In order to comprehend the immense possibilities of the problem before the management, let us consider the amount of gas that passes through a large fan, say one that is handling 200,000 cu.ft. of air per min. Assuming that this air coming from the Loomis colliery contains, as stated in Mr. Owen's letter, 1 per cent. of methane and the specific gravity of the gas being 0.559, the weight of gas passing through the fan in 24 hours would be $24 \times 60(0.01 \times 200{,}000)(0.559 \times 0.076) \div 2000 = 61.177$ tons.

Now, as estimated by Mr. Owens, the complete combustion of 1 lb. of methane generates 23,513 B.t.u. But the calculation shows the escape of $(61.177 \times 2000) \div 24 =$ say 5100 lb. of methane per hour. Then, if this weight of methane is burned to carbon dioxide and water, each pound of the gas yielding 23,513 B.t.u., (since 2545 B.t.u. per hour is equivalent to 1 hp.), this weight of gas escaping from the mine per hour is equivalent to $(5100 \times 23{,}513) \div 2545 = 47{,}000$ hp. The figures showing this tremendous potentiality in the return air of a gassy mine are staggering, to say the least.

Referring again to the tests made at the Loomis colliery and the attendant dangers mentioned by Mr. Owens, it can be said that arrangements are being made to increase or decrease the amount of pure air, which is added to the mixture drawn from the mine, so as to maintain a more uniform degree of inflammability and keep the mixture well below the explosive limit of the gas. It may even be found possible to make this control automatic, so that should there suddenly occur an increased percentage of gas in the mine air, this would be at once compensated by a corresponding increase in the addition of pure air, before the mixture enters the furnace.

The suggestion has also been made that the pipe line may be further protected by a gauze that will isolate the firebox of the furnace from the mine, after the principle of the safety lamp. It is further stated that a careful watch will be kept on barometric changes, knowing that a falling barometer is commonly followed by an increased outflow of gas in the mine. When these precautions are taken, it does not appear to me that any trouble need be anticipated, and the ultimate success of the plan will certainly reflect much credit on the men responsible for its development.

West Pittston, Penn. RICHARD BOWEN.

Drawing Pillars in Machine Mining

Letter No. 10—Referring to the letter of D. F. M., *Coal Age*, Feb. 6, p. 288, permit me to say that I agree with him in respect to the method that he has explained of drawing back the pillars with machines. There is one point, however, that I think is misstated in his letter. I have reference to the fact that the pillars should be attacked from the side opposite to the fall and not as explained in that letter, "by cutting through the rib in No. 1 room with the machines."[1]

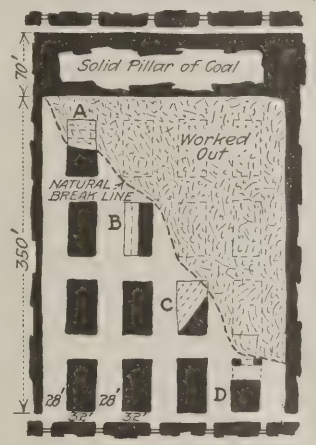
If the pillar is cut through from No. 1 room, there will be left what I call a "pick stump." When this stump is removed, there remains too little support for No. 2 pillar, which is apt to be crushed by the weight thrown on the end of that pillar, which is about 50 ft. back of the first pillar, the road in No. 2 room being all open.

Instead, however, the first pillar should be started and cut through from No. 2 room or on the side opposite to the fall, which will give better protection while the cut is being made and avoid the road's being closed before the remaining stump is all removed. In the same manner, No. 2 pillar should be cut through from No. 3 room, and the same order followed in all the rooms.

It is best to keep the line of pillar work on an angle of about 45 deg., which tends to cause the roof to break more against the rib of the pillar, and less weight is thrown on the pick stump, which is then removed with less difficulty than where the pressure is thrown with greater force on the supporting stump, as must be the case in the figure on page 288.

Crafton, Penn. RICHARD MCDOUGALL.

Letter No. 11—We are drawing pillars, with Sullivan machines, under almost identical conditions with those mentioned by "Operator," *Coal Age*, Jan. 2, p. 32. The



[1]This correction was made by D. F. M. in a second letter that more fully explained his sketch and which was published in *Coal Age*, Feb. 27, p. 415.

coal seam varies from 4½ to 5 ft., in thickness, and is overlaid with from 30 to 40 ft. of solid sandstone, at a depth reaching from 50 to 800 ft. below the surface. The lower half of the seam is a hard splint coal, while the upper half is softer and contains a 6-in. band of laminated or bone coal.

In our mine, the rooms are driven on 60-ft. centers and are 28 ft. wide and 350 ft. long. Rooms are opened on one side, only, of each pair of headings, and a solid pillar of coal, 70 ft. thick, is left at the head of the rooms, for the protection of the air-course of the next pair of butt headings. Twenty of these rooms form a panel.

When drawing back the pillars, several different methods have been tried, with the object of obtaining the largest possible recovery of coal with the machines. We have found that almost any method will work well, for the first 150 or 200 ft., when starting away from the solid barrier pillar. But, when the first fall occurs and a little weight is thus thrown on the pillars, the proposition grows more difficult, and it becomes necessary to adopt a method that will then give the best results.

The accompanying figure shows the work of drawing back the pillars in progress in a single panel. Four methods of attack are shown at *A*, *B*, *C* and *D*. At *A*, the pillar is shown as being cut across on the end, using the machines for that purpose. In this method, however, it was found that when a fall started it would usually come suddenly, and the roof would break tight to the face, the fall frequently catching the track. It can be said, however, that this method works well in a slate top that is carefully timbered.

METHODS OF CUTTING PILLARS

In the second method shown at *B*, the pillar is attacked by slabbing the rib, which is undercut the entire length of the pillar with the machine. This method worked well, until the thickness of the pillar was reduced to about 10 ft., after which the work became very dangerous, as the portion remaining was the only solid support for a considerable area of roof. While the weight resting on this stump was not sufficient to make it easily mined with the pick, any attempt to use the machine resulted in the coal settling down in a manner that made very hard cutting. Moreover, there was the added danger that the whole exposed area of roof would fall with the coal. It has been our luck to have two machines caught, in the attempt to use this method. They were both badly smashed.

The plan of starting the attack on the inby corner of the pillar and cutting out the coal on the bias, as shown at *C*, gave a little better success, but presented the disadvantage that when a big fall occurred, it was very apt to follow a featheredge and extend up into the rooms, thus cutting off the working face and making it very difficult to recover the balance of the pillar. Usually, a portion of this coal would have to be left, which was sure to give trouble later.

In all of these methods, timbers must be set regularly for protection against loose roof, but excessive timbering is of no avail. While large posts or many posts are useful at times, for special purposes, they generally serve to delay a fall, for a short time only; and when this finally occurs, the fall is greater and extends farther up into the rooms.

Our experience is that the best method to employ, and the one that recovers the most coal with the greatest regularity and safety, is the method shown at *D*. As this method has been fully described in previous letters, in *Coal Age*, it is only necessary to say, here, that a crosscut is first driven through the pillar with the machine, leaving about 6 ft. of solid coal on the gob side, for the protection of the work. The center of this stump is then cut out by the machine, leaving the two small stumps, as shown, one at each corner, to be removed by the pick.

This method has the advantage that the cut is always in the solid, with no large open areas behind the machine. It is economical of timber, the roof being supported by the coal stump, until the machine has finished its work and is withdrawn. In the use of the first method explained, roof falls occurred in increments of from 60 to 100 ft., while in the last method mentioned, these increments were reduced to from 18 to 30 ft., with a less thickness and a better control of the fall when the roof started to break.

Stone, Ky. MINING ENGINEER.

Waste of Coal

Letter No. 4—When Joseph R. Thomas remarked, in his excellent letter, *Coal Age*, Jan. 16, p. 160, that "we will never miss the coal till the fire goes out and the bin is empty," he could not have stated the truth more emphatically. He has done well to suggest a discussion of this subject from a practical standpoint.

Most men will agree that war-time requirements have made two things clearly discernible by the public eye. Either mining methods have very greatly improved, or the higher price paid for coal has caused operators throughout the country to mine and send to market coal that could not be mined at a profit, under the low prices prevailing previous to the war. Surely, there never was a time in the history of this country when the coal mines have been worked to their capacity, as during the past year or two.

LARGE RECOVERY OF COAL UNDER WAR STRESS

While there is no question but that much coal has been and is still being wasted by improper methods of mining and the careless disregard of necessary precautions on the part of both miners and mine officials alike, yet it cannot be denied that the war crisis made it possible to recover much coal that was previously considered as unmineable at a profit. I will cite a single instance that came to my notice some time since.

In a certain bituminous mine, the coal pitched so heavily in one section of the workings that cars could not be taken to the face. Still, the pitch was not great enough to cause the coal to slide down the chutes. For this reason, work was abandoned in that section and the miners transferred to a portion of the mine where the conditions were more favorable. It was not long, however, before all the available coal in that section was worked out and the foreman was obliged to again consider the working of the coal that he had previously abandoned.

Such was now the demand for coal that the foreman ordered sheet iron to lay in the floor of the chutes, which enabled the coal to slide freely to the heading below. Previous to this he had argued that the price paid for coal would not admit of this extra expense. Even then it was a common remark among the miners that the company would never get enough coal from that section to pay for the sheet iron; but the results soon proved to the contrary.

While one cannot say that the use of this sheet iron was an improved method of mining the coal, it resulted in saving what would otherwise have been an enormous waste of good coal. Lining the chutes with sheet iron, in such cases, has been in use for years, in the anthracite region, and this foreman simply used the same means when the situation required or the opportunity presented itself in the bituminous field.

Rapid Growth of Small Operations

Another feature, which has been brought to the notice of *Coal Age* readers, and has led to the development of large quantities of coal that was previously considered unmineable, is the number of small mines that were opened everywhere because of the extraordinary demand for coal during the war period. Many of these mines were isolated from railroads or other shipping facilities and had to be worked as "wagon mines."

In other cases, much coal was recovered from the outcroppings of larger mines, that had previously been abandoned. There is little doubt but that these small operations supplied much local trade and made it possible to devote the entire output of railroad mines to supply the needs of the war. Since much of this coal would never have been mined, it is clear that the war crisis has had a good effect in making plain the fact that much coal formerly regarded as unmineable and abandoned can and should be utilized.

There is no question but that, as indicated in Mr. Thomas' letter, much coal is wasted by careless miners not cleaning their places and allowing good coal to become lost in the gob, as well as in other ways, such as falling off the cars when being hauled to the slope bottom, because the car was improperly loaded or, perhaps, badly in need of repairs. A good foreman will see that the causes for such waste are removed as far as possible and careless miners trained to better habits.

Roads over which coal is daily hauled should be cleaned at regular intervals and kept in good condition to reduce this waste to a minimum. It must be remembered that every ton of coal lost or wasted shortens the life of the mine and reduces its value. Conservation of coal has been preached for the past ten years and yet many fail to consider its importance. It is hoped that these will be impressed with such a discussion.

Jacob, Penn. H. G. Cockill.

Reducing Ventilation at Firing Time

Letter No. 5—I recall distinctly that this subject was discussed in *Coal Age* several years ago. As I did not voice my sentiments at that time, the reopening of the discussion affords me an opportunity to express a few thoughts that are, perhaps, worthy of some consideration.

It is my belief that any attempt to reduce the ventilation in a mine, at the time of shooting, should be considered as an acknowledgement that a dangerous condition exists that requires some modification of the ventilating system, in order to avert trouble. If this is the case, it is a virtual admission of inefficiency, in respect to the ventilating system in use. All obtainable statistics relating to accidents in mines have shown conclusively that the majority of these accidents are either the direct or indirect result of carelessness or inefficiency, for which there is no excuse.

It is useless to argue this question, having in mind the presence of explosive gas only, since gas does not constitute the real danger in respect to explosions. The examination of mines where explosions have occurred invariably reveals the presence of coke that has been deposited on the ribs and timbers, which is evidence that dust and not gas is the real danger that must be avoided.

For over a century dust has been the main factor that has played havoc in the mines and proved itself the dangerous enemy of the coal-mining industry. In the year 1803, a Mr. Buddle, one of the pioneers in British coal mining, stated in his report of an explosion that had occurred in a dry and dusty but nongaseous mine that the men were burned by incandescent coal dust carried by the air current.

Now, the old saying is that "the value of a tooth is reduced where there is nothing for it to do." Working on this principle, the most effective method of dealing with the dust in coal mining is to treat it in a manner that will render it inactive and thus destroy its value in respect to producing an explosion.

The methods of treatment of coal dust have been fully explained in past issues of *Coal Age*, and I think it has been fully proved that the best method of keeping a dusty mine safe, at shooting time, is to employ a systematic system of sprinkling and washing down the ribs and timbers where the dust has accumulated. In addition to this, all accumulations of dust on roadways and travelingways should be removed regularly from the mine. Experience.

Birmingham, Ala.

Efficiency in Mine Management

Letter No. 4—In a recent letter that appeared in *Coal Age*, Jan. 30, p. 246, the writer referred to the position of mine superintendent as not being "an office job." The reference brought to my mind a conception that I formerly had of that official. I regarded him as a man who was able to produce the desired tonnage at a satisfactorily low cost. I thought of him as spending the greater part of his time in the office and only making an occasional inspection of the mine, which he generally left to the charge of the mine foreman.

A few years of close observance have shown me that there are many attributes needful to make a successful mine superintendent. He must, of course, be able to produce coal at a low cost and keep the mine in good condition and safe for work; besides, he must possess a sense of fairness that will enable him to see the other fellow's side of a question; he must also manifest an ever-ready sympathy, tact and diplomacy, together with not too keen a sense of humor in all his dealings.

To define what is a superintendent is about as difficult as to answer the question, "How old is Ann?" A

picture arises in my mind of the superintendent of a certain large operation. This man had been in charge for several years and had made himself familiar with the employees and their families. So successful had he been that there was little change among the mine employees; few were hired or discharged. Many of the men had been in the employ of the company for years and had built their homes, which was true alike of both the foreign and American miners working for that company. It may be amusing but, to my mind, it should prove instructive to cite, in order, the events of a single day in that superintendent's life. The narration would read as follows:

One Day's Record in the Affairs of a Successful Superintendent

Going to the office at 7:30, he started to open and read the mail, only to be interrupted by the electrician who came in from the power house with a list of needed supplies and repair parts and departed, after a few minutes' talk on some phase of his work. The superintendent resumes his task of reading over the mail and dictates a letter, in the midst of which he answers the telephone and again takes up the dictation only to be interrupted by Dick H., who comes in with the request, "Will the superintendent please send a carpenter to fix the back porch of my house, today, as the baby fell down the steps and skinned her nose." The superintendent promises and spends a few minutes to comment on the merits of the aforesaid baby, it being the man's only child.

On the departure of the much-pleased father, the interrupted dictation is once more hardly under way when the foreman calls up on the 'phone and gives an order for supplies that must be sent into the mine at once. That matter being attended to, the next visitor is the stableboss, who brings the information that "the gray mare Lizzie is off her feed." The superintendent goes carefully over the symptoms of the mare and then reads from Gleason's Horse Book, after which he concludes that the illness is not serious enough to call a veterinarian. He gives the stableboss some remedies and instructions and turns again to his dictation.

A few moments later, Mike Russ slips in to know if he can have enough bricks to build him an oven. The oven question being settled, Mrs. T appears and asks if it would be all right for her to move into the house that Mrs K has just vacated. Inquiry by the superintendent brings out the fact that Mrs T's reason for making the change is that Nick Slovak's chickens scratch up her flower beds, which the superintendent promises to remedy by building a more substantial fence between the properties.

The superintendent, here, puts in a long-distance call and has hardly done so when Mrs. T bursts into the office with a tale of woe of how Mrs. K had called her names; and "won't the superintendent please move Mrs. K into some other part of the town." Immediately after, Mrs. K appears on the scene with a similar tale of woe and some few minutes and the utmost diplomacy on the part of the superintendent are required to subdue that irate woman and restore her surface calm. This episode is happily cut short by the ring of the telephone. A few minutes' talk over the 'phone is followed by the carpenter, who comes in with an order for four panes of glass for house No. 77, stating that Jones' kids broke two windows playing "Andy Over."

The noon hour has now nearly arrived and, after a little routine work, the superintendent goes to lunch. Lunch over, he makes a brief visit to the power house, tipple or store, often taking a run into the mine, which may occupy the rest of the day. Not going into the mine, he starts for the office within an hour, but is intercepted on his way by Mrs. I, who wants a donation for the minister's new furnace. This woman is a born talker and relates at some length her experiences in the hospital, when she broke her arm last fall. The superintendent fidgets from one foot to the other and at last is glad to escape with a much-flattened pocketbook.

Finding a salesman in waiting at the office, the superintendent gives him an order for supplies, chats a few minutes and then turns to some work, going over the reports from the mine. In this, he is interrupted by Bob L, who wants to know why he is charged $6 for rent instead of the $4 that he is accustomed to pay. Another caller claims that he is short two cars and the superintendent turns him over to the bookkeeper, asking the latter to explain. Then, John Czek asks the superintendent if he can help him get out his naturalization papers, which the superintendent willingly does. Next, Charlie Y comes out of the mine with a cut on his head and, in the absence of the company doctor, the superintendent dresses the wound, putting in one or two stitches. This done, he barely has time to sign a few letters when his wife calls to know if he is ever coming home to dinner.

Responding to the dinner call, this affable superintendent had just left his desk when Mrs. R comes in to ask if he will please address a letter for her to her boy in France, as she does not write very well. Unlocking his desk, he addresses the letter and goes home to dinner. The meal is but half-eaten, however, when a loud knock at the door announces Dick T who wants the superintendent to come at once to his house, stating that two of his boarders got into a fight, with the result that one knocked the other down and he thought the man was dead. Leaving his dinner, the superintendent responds to this call, also, and finds much to his relief that the man was only stunned. He quickly settles the trouble between the fighters and goes home.

Reaching his house and the meal being scarcely finished, Tom W appears at the door with his wife, bearing a peculiar-looking package under his arm, which proves to be a hen, a half-dozen fresh eggs, and a pumpkin pie, all of which the good woman presents to the superintendent's wife with an appropriate speech and receives her thanks. Tom W then broaches the subject to the superintendent of his proposed new house and asks his help in arranging the plans and contracts. This the superintendent gladly agrees to do, and the three depart for the office, the superintendent returning home about 9:30 or 10 o'clock.

Such is the full day of one active and successful mine superintendent.

Spectator.

———, W. Va.

Efficiency in Firebossing

Letter No. 8—From the reading of Letter No. 3 on this subject, *Coal Age*, Jan. 23, p. 199, I am inclined to think that its writer, Edward H. Coxe, must be a superintendent. Speaking from my own present position as mine foreman and with a full knowledge of the duties of a competent fireboss, permit me to say that when a fireboss does his duty, the mine foreman will not need to set him to work digging a ditch or timbering a roadway.

Allow me to suggest to Mr. Coxe that he acquaint himself a little more with the requirements of the state mining law (Penn.) and then read up a little on accidents and how to prevent them in coal mining. If this is done with the sincere purpose of making a coal mine safe for work, the result cannot be otherwise than to change his opinion in respect to the daily employment of firebosses.

In many cases, the fireboss, having made his first examination of the mine, can assist in giving out the lamps to the men and, if he is on his job, he will explain, in detail, to each man who works in his section, what conditions he found in his place. He will willingly give the mine foreman an idea of what coal is loaded and ready to haul, and make other suggestions regarding work that must be done on the roads and in the working places.

A little later, the competent fireboss will be found making the second round in his section. This time, he gives more attention to the examination of the roof and observes carefully the manner in which the miners perform their work. The balance of his shift is spent talking with each man and advising him in regard to keeping his place safe.

Where pillars are being drawn, the fireboss must climb well up on the falls to ascertain the condition. Naturally, he performs many minor tasks such as giving information to drivers, assisting in lifting a car onto the track where it has been derailed, or helping a miner to set a post under a loose piece of top.

Such is a brief outline of a good fireboss' daily work. But, too often it happens that a fireboss is only interested in the theory of his work, as far as it will assist him in getting his certificate. When that is secured the books are sold or thrown aside and given no further attention or study. Such men seldom prove efficient or competent.

Incompetency, however, is not confined to firebossing, and I cannot refrain from saying a word here in regard to its effect in the mine when a superintendent is incompetent. Either there is a lack of proper supervision of the work, on his part, or the orders given by him prove impracticable and cause much trouble and friction in the mine.

At times, it has happened that good mine foremen have been obliged to resign their position, on account of the incompetency of their superiors in office. When that is the case, time is required to break in a new man and much loss results to the company. In my opinion, every mine superintendent should have at least eight or ten years' practical mining experience before assuming the duties of that office. He should hold a first-class, mine foreman's certificate.

Oliphant Furnace, Penn. JOHN H. WILEY.

Letter No. 9—Holding certificates, as I do, for both mineboss and fireboss, in this state, has made me much interested in the discussion, in *Coal Age*, regarding the latter position, which certainly has its good and bad points. Some time ago, I contemplated taking a position of fireboss that was offered me, in a certain mine, but asked that the place be held open for a few days, in order to give me time to consider it.

The advantages of firebossing may be briefly stated as follows: The position offers regular work and is not as laborious as most of the work performed in coal mining. The work is much more interesting than that of loading coal and offers greater opportunity for promotion.

THE DIFFICULTIES OF FIREBOSSING

On the other hand, there are disadvantages connected with firebossing, and these should always be considered, before a man takes upon himself the duties of that position. In the first place, the work of firebossing requires a man to leave his home in the early morning hours and start his examination of the mine alone. He must face many dangers, which no one understands better than the one who has encountered them. The fireboss is responsible for the safety of every portion of the section in his charge. His work must be completed and he must be back at the entrance of the mine in time to make his report before the men proceed to work.

Aside from these difficulties and dangers that surround the fireboss, in the performance of his work, there is too often a disposition on the part of a foreman to treat the fireboss in a way that is not pleasant. Frequently, his work is underrated as being of less importance than that of the foreman who has full charge of the mine. In the State of Indiana, I may say that more technical knowledge is required of a candidate for the position of fireboss than is necessary to secure a certificate to act as mineboss or foreman, and this fact may cause some foremen to berate the work of the fireboss.

To such an extent did this condition exist here, some years ago, that there was much talk of the firebosses organizing for their own protection. They hoped, by pooling their strength, to overcome the growing injustice that they felt was being done them, and secure better recognition and increase their chances for promotion.

ESSENTIALS TO SECURING HIGHEST EFFICIENCY

The question of attaining the highest efficiency in firebossing is well worthy of discussion and I want to make the following suggestions:

1. The ventilation of the mine should be entirely in the charge of the fireboss as it affects, primarily, his work of examining the mine, and is the chief element in securing safe and healthful conditions.

2. The fireboss should be given no more territory to examine and supervise than will permit him to do that work in a thorough manner. He should be given men to build all necessary doors, stoppings and overcasts and to assist in erecting brattices where these are required.

3. While I see nothing wrong in a fireboss turning his hand to do any work that may be required of him, it must be admitted that where a fireboss is put to loading coal, laying track and performing other work, to the detriment of his own, the effect will be to lower his prestige and impair his authority. There must be strict discipline to insure safety in coal mining.

4. The examination of a mine should never be started five or six hours before the time for work to begin in the mine. Particularly in a gassy mine, the mining law should restrict the time for beginning the morning examination to two or, at the most, three hours before the men go to work.

5. The fireboss should live as near as practicable to the mine, in order to avoid loss of time in going to and from his work, and that he will be able to reach the mine quickly in case his presence is needed in any emergency that may arise. In many cases, living close to the mine would mean to occupy one of the company houses, which are too often set close together with little opportunity for gardens and outhouses, such as barns, cow-sheds, and yardroom for hens and chickens, which many firebosses desire in their home surroundings. It is these comforts of life that add to the efficiency of all mine employees, particularly of firebosses, whose early morning work shortens the hours of his shift, in the day, and gives him opportunity for some outdoor work and exercise.

In closing, I want to mention that there is a custom prevailing in some of the mines in this state, where the duties of the fireboss are light, to make the roomboss perform the duties of a fireboss in connection with his own work. The roomboss, in Indiana, is really an assistant mineboss (foreman). He must hold a mineboss certificate, and is also required to have a fireboss certificate if his work combines the two positions.

Linton, Ind. W. H. LUXTON.

INQUIRIES OF GENERAL INTEREST

EDITED BY JAMES T. BEARD

Roof Conditions in Longwall Work

I have a longwall proposition that I would like to submit to the readers of *Coal Age* and get their ideas in regard to the best method to adopt in order to secure the best results. The proposition is as follows:

Ours is a bituminous coal of average hardness and 3 ft. 4 in. thick. Immediately above the coal is a 9-in. layer of very hard sandrock, which is overlaid with about 3 ft. of a soapstone formation. Above the soapstone, again, is sandrock. The coal is underlaid with 3 ft. of fireclay, which heaves slightly under the roof pressure.

The question I want to ask, particularly, is, Should this top be broken at regular intervals, using cogs for that purpose; or should the packs be so arranged that the roof will settle gradually on the waste, without breaking? SANDROCK.

Landstreet, Penn.

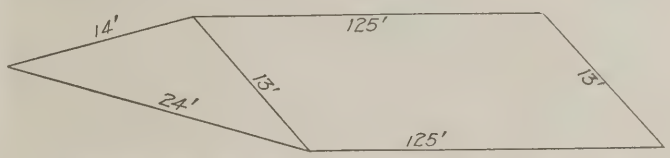
Coal Age will be glad to receive the suggestions of its practical readers who have worked longwall under conditions similar to those mentioned in this inquiry. It is to be regretted that the correspondent has not given the depth of cover. However, this can be assumed as varying from 200 to 300 ft.

The experience of the editor, in dealing with longwall work, is that, as a general proposition, it is far better to build solid packwalls and arrange these in a manner that will induce a regular and uniform settlement of the roof. The underlying principle of longwall work is to maintain a traveling weight or overburden bearing on the face of the coal and only sufficient to break down the coal when the latter has been properly mined.

In the best longwall practice, the roof should not be broken if it can be avoided as that would at once relieve the pressure, which must be utilized to break the coal. Moreover, the roof is liable to break off at the coal face, unless it is properly supported and controlled by uniform packs. The breaking of the roof at the face is the one thing that must always be avoided, in longwall work, as it destroys the principle on which this system of mining depends.

Tonnage per Foot-Acre

Please explain the rule for estimating the number of bushels of bituminous coal underlying an acre of land when the seam has a uniform thickness of 5 ft. This coal will average 80 lb. to the bushel, or 2000 ÷ 80 = 25 bu. per ton. There is, I understand, a rule for estimating the tonnage, which is generally used in practice. BITUMINOUS.



Martins Ferry, Ohio.

The rule to which this correspondent refers is one that is based on an assumed extraction of two-thirds of the coal underlying an acre, which was quite common practice, in bituminous mining more than a decade ago. The average specific gravity of bituminous coal can be taken as 1.27, which makes its weight 1.27 × 62.5 = say 80 lb. per cu.ft. There are 43,560 sq.ft. in an acre; and the weight of coal per acre, for a thickness of 1 ft., is, therefore (80 × 43,560) ÷ 2000 = 1742 short tons. Then, assuming a two-thirds extraction, the weight of coal available per foot-acre is $\frac{2}{3}(1742) = 1161$ short tons.

On this basis, the common practice was to estimate 1200 short tons, per foot-acre, of bituminous coal. Since the extraction of coal, at the present day, far exceeds two-thirds of the entire amount, a closer estimate for bituminous coal would be to allow 1500 short tons, per foot-acre, as the available coal in a seam.

Measuring a Coal Pile

Kindly permit me to ask how a coal pile having the shape and dimensions given in my sketch can be measured to ascertain its contents. The ground is flat. The coal was unloaded, by hand, along a railroad track.

SHOWING SHAPE AND DIMENSIONS OF COAL PILE

From the ridge line, the coal sloped each way uniformly, the length of slope being 13 ft. on one side and 14 ft. on the other side, while the spread at the base measures 24 ft. across. Kindly explain the manner in which the contents of this pile is calculated. The coal is mine-run bituminous coal. COAL DEALER.

Chicago, Ill.

In this inquiry, no data are given to determine the slope at the two ends of the pile; but, judging from the sketch, the coal may be regarded as stacked between two walls, making the two ends vertical and parallel. On this assumption, it is only necessary to calculate the area of a triangle whose three sides are 13, 14 and 24 ft. in length; and multiply this area by the length of the pile, which is 125 ft., as indicated in the figure.

The area of a triangle the three sides of which are known is calculated by the formula,

$$a = \sqrt{s(s-a)(s-b)(s-c)}$$

To apply this formula, let a = the sectional area of one end of the pile and s = the half-sum of the three sides, a, b, c. The half sum of these three sides is $\frac{1}{2}(13 + 14 + 24) = 25.5$ ft. and, substituting this and the given values in the formula, we have,

$$a = \sqrt{25.5(25.5-13)(25.5-14)(25.5-24)} = 74.15 \text{ sq.ft.}$$

The cubical contents of this pile is, therefore, 74.15 × 125 = say 9269 cu.ft. Mine-run bituminous coal measures 40 cu.ft. to the short ton. The weight of coal in this pile is, therefore, 9269 ÷ 40 = $231\frac{3}{4}$ short tons. Estimated in bushels, the pile contains, approximately, $231\frac{3}{4}$ × 25 = 5793 bushels.

EXAMINATION QUESTIONS

EDITED BY JAMES T. BEARD

Alabama Second-Class Examination Birmingham, Jan. 20-23, 1919

(Selected Questions)

Ques.—What dangers arise from blasting coal out of the solid?

Ans.—Coal that is blasted out of the solid is not mined or side cut, and there is little opportunity given for the charge of powder to do its work properly in breaking down the coal. Under certain favorable conditions in the coal seam, it is possible to employ what is sometimes called a "grip shot," in which the drill-hole is inclined at a sharp angle with the face of the coal. While this shot may not be mined or side cut, the butt cleats often existing in the coal cause it to break easily and there is no particular danger.

On the other hand, when these conditions do not exist and the shot is not mined or side cut, or when the charge is located on the solid beyond the cutting, there is danger of a blownout or windy shot being produced. In either case, much of the force of the explosion is spent on the air, instead of being absorbed in the breaking down of the coal. A large amount of heat and flame is produced, and there is danger of gas or dust being ignited and causing a local explosion, which may or may not be transmitted throughout the mine, depending on the condition of the mine air and the workings.

Ques.—How would you timber an airway when the bottom is soft or wet?

Ans.—Where the bottom is soft or wet, there is danger of the posts supporting the roof being forced down through the clay, leaving the roof free to settle heavily on the pillars, which are crushed by the undue pressure thus thrown on them. To avoid this contingency, the posts should be set on footboards whenever the bottom is soft or wet, so as to distribute the pressure and give a firmer footing to the posts. Under these conditions, extra precaution is required, in order to reduce to a minimum the danger of squeeze or creep, particularly if a good width of pillar has not been provided to avoid this trouble. In airways where the roof conditions are such as to require the timber frames to be set but a few feet apart, side sills are generally used instead of footboards. The bottom should then be well drained by ditches on both sides of the track.

Ques.—What dangers and difficulties are encountered from a mine squeeze?

Ans.—The occurrence of a squeeze in mine workings throws an undue pressure on the pillars left to support the roof and protect the roads and airways. The mining of the pillar coal is then more difficult and dangerous, because of the great weight on the pillars, which crushes the coal, and because of the danger of heavy roof falls when the pillars are withdrawn. Owing to the crushing of the pillars, it frequently happens that much good coal is lost beyond recovery. When roads are cut off or completely closed by the advance of the squeeze much tracking and timber also are lost.

Ques.—When extracting pillars, how should the general line of face be kept?

Ans.—The ends of the pillars should be kept in line with each other so as to provide a continuous break line, and produce a more uniform and gradual settlement of the roof in the gob. Where the line of fracture is straight a more uniform pressure is thrown on all the pillars alike, but when one or more pillars fall behind the others, the coal in them is crushed by the undue weight they carry. The line of fracture will generally need to be kept at an angle approaching 45 deg. with the entry to obtain the best results; but this is not always the case, as much will depend on the conditions in the seam and the overlying strata. These conditions must be carefully studied to determine the best line of fracture in drawing back the pillars.

Ques.—What should be considered in determining the size of pillars, in mines?

Ans.—The chief factors in determining the size of pillars, in coal mining, are the depth of cover, width of opening, thickness and character of the coal, nature of the overlying and underlying strata, and the time that the pillars must remain before being withdrawn. The presence of slips or fault lines in the formations must also be considered with regard to the effect produced on the working of the seam. The presence of water in the strata will soften the floor and roof of the seam, and require greater pillar support than is necessary in dry workings. The presence of gas in the floor or the roof of a coal seam may give unexpected trouble by causing the bottom to heave or the roof to fall.

Ques.—Why is the single-entry system of operating almost certain to prove a failure?

Ans.—In a single-entry system of working, the air current must be returned along the faces of the rooms, since there is no separate return airway provided. In this system, a fall of roof at the face of one or more rooms may block the entire circulation in the mine, until another opening can be made to conduct the air current to the return opening. When this happens the system of ventilation is a failure.

Ques.—What is the best mode of ventilation to adopt?

Ans.—The plan of ventilation of a mine should be such as to meet the particular requirements. There should always be a separate intake and return airway provided, except in longwall work, where the air travels the working face throughout the most of its course. In a small mine, the double-entry system will generally prove sufficient to meet every requirement; but, in a gassy mine, three or more main entries may be needed, in order to provide ample area in the return airway. In many mines producing large tonnages it is necessary to provide a multiple system of main entries, in order to secure the best results with regard to economy and safety. As the workings are extended, the mines should be divided into separate sections and each section ventilated by a separate air current. This is accomplished by splitting the main air current and building an air bridge at that point to carry the air across.

Book Reviews

To Avoid Blind Guesses at Probable Cost

MECHANICAL AND ELECTRICAL COST DATA. By Halbert P. Gillette and Richard T. Dana. Pp. xvii + 1716 + 16 index; 4½ x 7 in.; adequately, but not profusely, illustrated. McGraw-Hill Book Co., Inc., 239 West 39th St., New York City, publisher. Leather cover. Price, $6 net.

The weakest element in the engineer's whole equipment is in costs. The bulk of the training of the engineer tends to lead him away from the subject. Most of the craft have been drawn to the engineering profession by a delight in pure science, and scientists at heart they always remain. But they absorb a few "base mechanical" facts, to quote Shakespeare, in the course of their college or university training, though such facts are grudgingly given by instructors and unwillingly accepted by the student. The cost element of training comes last. It is the hardest information for the instructor to secure; it is contrary to his psychology and, as it is also alien to the psychology of the students, it is quite generally neglected.

Manager Knows, Yet Asks Engineer to Estimate

Besides, both preceptor and pupil argue, the study will serve only for a while, for prices are fleeting things, lasting only till the union forces a new wage scale, conditions of business introduce a new labor psychology, or the manufacturer prints a new discount table. But after all, despite the haughtiness and aloofness of such a superior being as the mining engineer believes himself to be, he must pay attention to the present and the ephemeral if he is to be successful. He is in an unfortunate position and one it is hard for him to correct. Under the present absurd division of labor, the manager does the buying, the bookkeeper keeps the accounts and the poor devil of an engineer estimates probable cost of construction. No wonder his estimates are too frequently a joke.

But how will a cost book based on pre-war figures help a man to learn as much or more than the manager who knows the real costs and propositions of manufacturers and who keeps all that knowledge in his managerial bosom Gillette and Dana in an introduction declare that such a book on "Mechanical and Electrical Cost Data" can and will help considerably, for any labor costs can be multiplied by the factor representing increase in wages and so corrected. They also declare that any machine costs can be determined when the increased cost factor has been determined for any one class of machine, for as one machine increases in cost another is almost sure to increase. So long as the design is not changed materially a fairly safe estimate can be made. The engineer must be patient. He cannot secure the impossible, and his judgment is shown in securing the best help that is offered.

Interest Charges During Construction

The writers of the book certainly open up ideas on valuation in their department entitled "General Economic Principles." The reviewer has looked long and unsuccessfully for a statement like the following:

"Very few operating companies charge any interest during construction, when new construction proceeds *pari passu* with renewals. In other words, after the original nucleus of the plant is built, the 'interest during construction' account, if ever there was one, is closed."

"If ever there was one," is a good reservation. The reviewer recalls one well-posted accountant who refused to allow for interest during construction unless that interest was actually paid to someone. If money was borrowed to build a plant, that plant was, by his way of reasoning, worth more than if the money was subscribed. When urged that work by a construction company was loaded with interest, profit and rick charges during construction he replied that he knew it, but to add interest during construction where a company constructed a plant with its own money was to credit a profit on the investment when no profit was actually made.

The section, just quoted on "General Economic Principles" contains many other wise considerations. Then follows "Depreciation, Repairs and Renewals," with a long table showing the estimated life of plant units in years, with the authorities for such estimates. This table is insufficiently detailed; for instance, ties for track construction are credited with a life of 8 years, of 13.3 years and 20 years. No attempt is made to differentiate the kind of ties of which the longevity is given. Steel, locust and hemlock ties are not given their appropriate longevities, nor is there any reference to the place and conditions of use.

Running rapidly over the book, Cost of Buildings, Chimneys, Moving and Installing, Fuel and Coal Handling, Steam Power, Internal Combustion Engines, Hydro-Electric Plants, Electric Light and Power Plants, Overhead and Underground Electric Transmission, Lighting and Wiring, Belts, Shafts and Motor Drives, Compressed Air, Gas Plants, Pumps and Pumping, Conveyors, Hoists, Cranes and Elevators, Heating, Cooking and Ventilating, Electric Railways and miscellaneous matters, such as arc welding, are taken up in turn. This is a handy book, a good companion to "Handbook of Cost Data" by Gillette and "Handbook of Construction Plant and Its Cost" by Dana. Every mining engineer's office of any pretension should contain all three. They do not cover the same ground, but supplement each other.

How To Store Goods With Profit

STORING: ITS ECONOMIC ASPECTS AND PROPER METHODS. By H. P. Twyford, Otis Elevator Co. Pages xvi + 196 + 5 index; 5 x 9¼ in.; 96 ill. D. Van Nostrand Co., 25 Park Place, New York, publisher. Cloth Boards. Price $3 net.

Provident storage was ever looked upon as one of the greatest of housewifely virtues—to put things by for future use, to keep them so that they would not spoil, to have them where they could be located even in the dark, to record their number, quality and purpose—these were primal duties and they remain so even today. But nowadays we buy in large quantities, and the problem becomes far larger.

As the purchaser has not expended on the product the labor that a housewife has expanded on hers, he is prone to forget just what he has on hand and to order it over again while he still has some of the material in reserve. He has not exerted himself to get it, so he doesn't feel the loss of his labor if the material spoils. Conversely, knowing these failings the manager is opposed to storing because he is afraid the stored material will not be used and because he anticipates that new material will be purchased whenever an emergency arises demanding the use of material of the kind stored.

Therefore methodical storage is the need of the hour, especially for large firms. It prevents excessive buying while permitting of speedy replacements when breakdowns occur. It assists in securing properly balanced buying, and it enables the manager to know just how well he is protected against unforeseen troubles.

Here is a book pointing out the economic questions related to storing, giving details regarding specifications, definitions and standardization, providing suggestions as to the location and equipment of the storeroom, showing what appliances facilitate its operation, detailing the manual, clerical and managerial work involved and then following the material from delivery to exit. Though more adapted to the larger storerooms of manufacturing concerns, it will afford the mine operator and manager many excellent suggestions.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Coal Production in Japan

An excerpt from *The Japan Chronicle* of Dec. 24 and 25, 1918, transmitted to the Bureau of Foreign and Domestic Commerce by Consul General George H. Scudmore, Yokohama, states that the output of Japanese coal mines during the last seven years was, in tons, as follows: In 1912, 15,709,663; 1913, 17,050,267; 1914, 17,289,861; 1915, 15,488,828; 1916, 17,476,803; 1917, 19,887,147; and 1918 (estimated), 20,835,254 tons. It will be seen that, compared with the output for 1915, which is the smallest during the last seven years, the 1918 estimate shows an increase of about 35 per cent.

At present about 26 yens ($12.95) per ton is quoted for Japan best and steam lump coal at Moji, and when freight, landing and other charges are taken into account the price at Kobe will be about 35 yen ($17.45). Opinions differ as to the outlook of the market. It is true, however, that though there has been a general decrease in the prices of other commodities since the armistice, there has been a continued advance in the price of coal.

At the end of November stocks at Moji and Wakamatsu, taken together (though Moji stocks alone showed an increase), showed a decrease of 55,000 tons compared with the preceding month, amounting to 149,000 tons. Stocks at the pit's mouth at the end of November were put at 296,000 tons, about 26,000 tons less than in October. Present stocks at Osaka amount to about 180,000 tons, a decrease of about 40,000 tons. Though stocks have diminished, there has been no particular change in the demand since the armistice, and it is thought that coal prices will continue at their present level, if not increase. On the other hand, the theory is advanced that the demand is bound to decrease as the result of the industrial slump caused by the termination of hostilities; and, as the number of coal miners will increase, owing to many workers being dismissed by industrial companies, there will be increased supplies in the future, naturally causing a decline in price.

Serious rioting is reported at Gelsenkirchen and other places in the Ruhr coalfield and conflicts between the military and Spartacists. The strikes are now said to have ended, but not before serious damage had been done to coke ovens and other industrial plant.

American Exports Set New Record

January exports from the United States, valued at $623,000,000, were announced by the Department of Commerce as exceeding any previous month in the history of American commerce. They compare with $505,000,000 for January, 1918, and $566,000,000 for December, 1918.

During the seven months ended with January, exports from the United States totaled $3,798,000,000, as compared with $3,450,000,000 for the corresponding period one year ago.

Imports during January were valued at $213,000,000, the report said, leaving a net trade balance in favor of the United States for the month of $410,000,000. Imports during January, 1918, were valued at $234,000,000, and during December, 1918, at $211,000,000.

Exports continued to show great strength in February, the total reaching $588,000,000 in value. This is a falling off from the record January total of $623,000,000, but as there were only 28 days in February, the daily average would appear to be even higher than in January. The total for the month represents an increase of approximately 42 per cent. over the $411,000,000 for February of last year. Exports for the eight months ended with February were valued at $4,386,000,000, as compared with $3,862,000,000 for the corresponding period of the previous year.

February imports are announced as $235,000,000, a gain over the $213,000,000 for January, and over the $208,000,000 for February, 1918. Imports for the eight months ended with February totaled $1,933,000,000, as against $1,841,000,000 for a similar period the previous year.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Mar. 17 states that the demand for steamers to take coal to the West Indies was a little better and that a number of charters were effected at the Chartering Committee's rates. The active demand at advancing rates for tonnage for general cargo to transatlantic ports is making it difficult to secure vessels to carry coal to South America, but there are occasional boats inquiring for such business that are willing to accept the Chartering Committee's rates. W. W. Battie & Co. expect to have a number of steamers in the near future that will be available for coals to South America.

The Chartering Committee's rates are as quoted below:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge. Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis., or $21 net, 600 tons dis.; Buenos Aires, $18.50 net, 1000 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.50 net, 500 tons dis. To Nitrate Range, $16.50 gross prepaid.

Sail (maximum)—Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. To Nitrate Range, $16.50 gross prepaid.

The coal crisis in Paris may now be considered at an end.

Exports of Anthracite and Bituminous Coal and Coke for the Calendar Years 1916, 1917 and 1918

(Compiled by Bureau of Foreign and Domestic Commerce)

Exported to	Twelve Months Ending December 1916 Tons	1916 Value	1917 Tons	1917 Value	1918 Tons	1918 Value

* Does not include fuel or bunker coal laden on vessels engaged in the foreign trade, which aggregated during the twelve months ending December, as follows: 1916, 7,825,731 tons, valued at $27,491,822; 1917, 6,883,176 tons, valued at $31,844,799; 1918, 5,626,175 tons, valued at $29,868,023.

Large Tonnage Allocated for Coal Export Trade

The increase in the coal exports is reflected clearly in the allocation of shipping made by the Shipping Board Mar. 17. The steamer "Salto" is to carry coal from New York to Montevideo, the "Glen White" from Hampton Roads to Brazil, the "West Indian" from New York to Uruguay, the "North Pines" from Hampton Roads to River Platte points, the "Snug Harbor" from Norfolk to the West Indies, the "Lake Ontario" from Hampton Roads to the west coast of South America, the "Point Lobos" from Hampton Roads to Hawaii.

In addition, the following vessels are assigned to take coal to Brazil: The "Randolph S. Warner," the "E. C. Pope," the "Bulano," the "Mojave," the "Andra," the "Chibiabos," the "Lakeside," the "Lake Shore," the "Biran," the "Lake Huron," the "Lakewood," the "Cranenest," the "Mineola," the "Randwijk," the "Larenberg," the "Sacarappa" and the "Bellatrix."

Other allocations for coal destined to West Indies points are as follows: The "Lake Akkra," the "Lake Forest," the "Lake Champlain," the "Frednes," the "Lake Buckeye," the "Lake Sebago," the "Lake Ledan," the "Lake Deval," the "Lake Butler," the "Lake Duncan," the "Lake Janet."

The following ships have been assigned for the carrying of coal to points on the Rio de la Plata: The "Prococyon," the "Sac City," the "Winterswijk." Other ships assigned to the west coast of South America are as follows: The "Saguache," the "Castle Point," the "Dalana," the "H. Ponteppidan." There was also a number of vessels assigned to the carrying of coal to the Pacific Coast, to New England and to various naval coaling stations. The total tonnage assigned for coal is 228,200.

Hampton Roads Coal Exports, February, 1919

	Gross Tons
Norfolk & Western R.R.	401,951
Virginian R.R.	210,284
Chesapeake & Ohio R.R.	184,973
Total	797,208

The War Trade Board announces that the export conservation list as of Mar. 1, 1919, includes coal and coke. Individual licenses, however, are not required to Canada and Newfoundland. Shipments of coal and coke to these destinations may be made under Special Export License R A C—63.

Commitments for Export

Instances have recently come to the attention of the War Trade Board wherein certain American exporters have been embarrassed by reason of the fact that they have entered into definite commitments for export shipments prior to the receipt of the necessary export licenses.

The War Trade Board takes this opportunity to renew its warnings to exporters that, although the importer in the country of destination may have contracted to purchase goods and may have cabled that he possesses the necessary import certificate, the prohibitions of the Trading with the Enemy Act and the necessity of maintaining the blockade conditions may prevent the issuance of an export license. In view of the present policy of the associated governments with respect to shipments to the countries contiguous to Germany, the War Trade Board is unable definitely to assure exporters in advance that licenses will be granted. For their own protection, therefore, exporters should obtain export licenses before making definite and unconditional commitments.

Import Duties on Coal and Coke

With American coal exporters seeking new fields for their product, a knowledge of the rates of duties levied on coal and coke shipped to the various countries, are of necessity of much interest to the coal industry. In making use of these rates it should be kept in mind by shippers that authoritative information in regard to the duties can be obtained only from the custom authorities of the country concerned. This precaution is advised by the Bureau of Foreign and Domestic Commerce, at Washington. The bureau also advises that to test the rates small trial shipments are advisable.

It is also explained that when two or more rates of duty are shown for the same article, products of the United States as a rule are admitted at the lowest rate ("conventional" or "minimum"), except: (1) Into France and French colonies, where (in the case of most articles) the "general" rate is applied; (2) into Canada, when the "general" rate is applied; and (3) into other British colonies, where the "preferential" rates (if any) are withheld from all non-British imports.

In some countries there is an addition of surtaxes which are to be added to the rates.

The following tabulation shows the rates of import duties levied by various countries to which American coal is sent:

	Rate of Duty
Austria-Hungary—Coal and coke	Free
Belgium—Coal and coke	Free
France—Coal or coke (general and minimum), francs per 100 kilos	0.12
Germany—Coal, anthracite, unmanufactured cannel coal, coke and gas coal, from all countries	Free
Italy—Coal and coke (general and conventional)	Free
Norway—Coal	Free
Portugal—Coal, per ton	0.345 milreis
Spain—Mineral coal. (Exemption of coal from import and transportation duties in Spain was granted by royal decree of Apr. 7, 1915. No announcement of the reimposition of the duty has been received.)	
Sweden—Coal and coke	Free
United Kingdom—Articles not specified in the tariff	Free
Russia—Coal. Imported by the Black Sea or the Sea of Azof, rubles per pound	0.066
Imported by the Baltic Sea, rubles per pound	0.0165
Coal imported by the White Sea is admitted free of duty.	

	General	Preferential
Canada—Coal, anthracite, anthracite coal dust	Free	Free
Bituminous slack coal, such as will pass through a ¾-in. screen, subject to regulations prescribed by the Minister of Customs, per ton	14c.	10c.
Plus ad valorem	7½ per cent.	5 per cent.
Coal, bituminous, round and run-of-mine, and coal not specified, per ton	53c.	35c.
Plus ad valorem	7½ per cent.	5 per cent.
Gibraltar—Coal	.....	Free

	Valuation per 1000 Kilos	Rate of Duty
Argentina—Coal	7.00	Free
	Per Kilo	
Bolivia—Coal	0.07	Free
Brazil—Coal	....	Free
Chile—Coal, not specified, and coke	....	Free
Colombia—Coal	....	Free
Ecuador—Coal	....	Free

	Valuation Pesos per 1000 Kilos	Rate of Duty
Paraguay—Coal	11.00	Free
Peru—Coal	.....	Free

	Valuation Pesos per 1000 Kilos	Rate of Duty Per Cent. of Valuation
Uruguay—Coal	10.00	6
Venezuela—Coal	....	Free
Costa Rica—Coal	.....	Free

	Rate of Duty Peso per Kilo
Guatemala—Coal except pulverized coal, gross weight	0.01¼
Honduras—Coal	Free
Nicaragua—Coal	Free
Panama—Articles not specified	Free
Salvador—Coal	Free
Finland—Coal	Free
Denmark—(Crown, 26.8c.) coal, per 100 kilos	0.03 crowns
Holland—Coal	Free
Switzerland—Coal	Free
Greece—Coal	Free
Turkey—Coal	Two (2) Piastres per 100 kilos
Bahamas—Coal	Free
Barbadoes—Coal and coke, per ton	2s. 6d.
Bermuda—Coal, per ton	2s.
	Ad Valorem
British Honduras—Coal	15 per cent.
Trinidad and Tobago—Coal, coke and patent fuel	Free
Jamaica—Coal, coke and patent fuel	Free

	Per Ton General	Per Ton British Preferential
British Guiana—Coal, bituminous	$0.50	$0.40
Other	.50	.50
Coke and patent fuel	.50	.50
Newfoundland and Laborador—Coal, anthracite imported through St. John's port	.70	.....
Coal imported through any other port	.50	.....
Dutch Guiana—Coal	Free	.....
Dutch West Indies—Coal	Free	.....
Dutch East Indies—Coal and coke	Free	.....

	Per 100 Kilos. Francs
St. Pierre and Miquelon—Coal	Free
Anthracite	0.10
Guadeloupe—Coal	Free
Martinique—Coal	Free
Mexico—Coal	Free
Haiti—Coal	$1.30 per 500 kilos or 1000 lb.
Cuba—Coal	Free
Virgin Islands—Coal	Free
Dominican Republic—Coal and screenings of coal (gross weight) 1000 kilos	$0.25
Coke (gross weight) 1000 kilos	.75
Fuel charcoal	5.00
Briquets of coal dust, screenings of coal waste, prepared for fuel, with or without the addition of other substances and other fuels (gross weight) 1000 kilos	3.00

COAL AND COKE NEWS

EDITED BY ALEX MOSS

Harrisburg, Penn.

Governor Sproul, who last week asked Attorney General Schaeffer to inquire into the power of the state to make an investigation of the proposed increases in the price of anthracite coal, on Mar. 19 indicated in correspondence made public between himself and a representative of independent operators, that an investigation by a legislative commission might be the most effective way to reach a decision as to whether the raise in price is justified.

The Governor also threw out the suggestion to the operators that if a way could be found to prevent, or even to defer, the proposed increase in coal prices until such an investigation has been made as will show that such an increase is justified, if it can be justified, a great deal will have been accomplished.

It is possible, it is said about the capitol, that an investigation might be averted.

Francis S. Brown, former Attorney General of the state, sees no way out for the coal operators except that they be allowed to charge the higher prices announced in their summer schedules. He pointed out that the high wages paid the mine workers, the increased transportation charges, and the fact that so little coal had been purchased this winter, had placed the coal men in a bad situation.

Coal operators who lease properties from the Girard estate have asked the Board of City Trusts of Philadelphia, which handles this estate, to relieve them of a certain portion of the royalties now paid under the increased price resulting from the higher wages. The matter is being placed before the court with a recommendation that the operators' appeal is a righteous one.

When the government raised the miners' wages a dollar, this was automatically added to the price per ton charged by the operator. In accordance with the terms of the Girard lease, the royalty increases proportionately with the gain in price, so that the operator was being taxed for the wage advance, on which he says he did not get any return. The operators ask that the royalty tax on this one dollar be taken off, as they cannot otherwise produce their coal without a loss.

Uniontown, Penn.

The Fayette County coal region continued to mark time during the past week, with but little change in the local situation over that of the preceding week. Approximately 500 additional coke ovens, widely scattered, were blown out in the region, and operation at plants still running averaged four days a week with additional employment given many workers at improvements and repairs being made at plants in order to put the operations into good shape for the prosperous run believed to be due in the immediate future.

The coal market continues to show signs of resuscitation. During the past two weeks there have been a number of inquiries concerning contracts, and the increased number in which these inquiries are being received is believed to be convincing proof that storage supplies have been depleted and that users will have to place orders immediately to keep their plants in operation. There is no storage supply in the region, and this means that when the contracts are signed work will be resumed immediately. Another encouraging development of the week was the receipt of some highly important inquiries from South American industrial concerns. A few cargoes of Fayette County coal have been shipped south during the past few months and there are indications now that some of the operators are to find a ready market in the South American field for their product.

Early stimulation of the coke industry is expected now following the announcement in Washington this week of agreement upon basic prices for steel commodities with basic pig iron at $25.75 a ton This indicates that the price of coke will be around $4.70 a ton if the ratio of 5.5 to 1, effective during the war between the price of pig iron and coke, is maintained. Operators generally throughout the region seem inclined to go along under the 5.5 to 1 ratio, but they point out that under present conditions they would be unable to supply coke at a profit at a price lower than $4.70. A number of contracts for the first quarter are about to expire and renewals were held up pending decision of the conference with the Industrial Board of the Department of Commerce and the iron and steel representatives, although in some instances arrangements were made to continue shipments on a month to month basis.

Announcement by Judge E. H. Gary, head of the iron and steel institute, that there was no intention at the present to interfere with the wage scales is reassuring to the region and the feeling of optimism which has been so manifest in the Fayette County field during the period of readjustment continues at high tide.

Charleston, W. Va.

The most encouraging development in West Virginia coal fields was the resumption of work at one or two large operations in the state on Mar. 17, after a suspension lasting over a considerable period. Otherwise conditions as a whole were unchanged in the mining industry of the state. There did not appear to be, during the second week of March, either any decrease in production or any appreciable increase, except in one district. That production is no longer on the toboggan was looked upon as being a favorable sign, but producers up until the last week or so had looked forward to a better market in the West, only to find after careful inquiry that little might be looked for in that respect for the time being.

The general resumption of coal traffic on the lakes is not expected as early this year as in years past. Naturally this will have an effect on other consuming areas, since the resumption of activity in the lake trade was considered reasonably certain of stimulating activity throughout the West. Since Western business has not been increased those districts whose products are usually consumed in that part of the country are working only about one-quarter of the time.

Generally speaking there is more activity in the East than in the West, if the direction of the bulk of the coal produced is to be taken as an index to conditions. However, the Pocahontas district has derived some business from Western sources, and it has helped to stimulate the production and sale of coal in that field to a considerable extent. Car shortages existing in several producing districts are attributed to the fact that the railroads have been under instructions to use only the larger capacity coal cars. This order, however, was rescinded on Mar. 16, at least as to some districts.

The export situation has proved to be discouraging to some West Virginia producers so far as vessels and rates are concerned.

Spokane, Wash.

"This year the coal mines of the Northwest will not operate 40 per cent. of the time, which means a heavy expense for the operators and a shortage of coal," states James S. Ramage, head of the Continental Fuel Co. and the Hawkeye Fuel Co.

For some time there has been serious over-production of coal in the Canadian and other districts from which Spokane and nearby cities receive their supply. About 80 per cent. of the steam coal used in this district comes from the mines of Canada, and a serious situation has developed in that country as evidenced by the recent report issued by the workingmen's compensation commission in the definite statement that cost of labor in producing coal is $2.60 a ton, which is above previous calculations and more than in other field with which Canadian mines compete.

It has been estimated from time to time in a general and unscientific manner that the labor cost of producing domestic coal was from $1.60 to $1.80 per ton. The coal industry in the province of Alberta is not on a very sound footing, and the outlook is far from reassuring. The reason for the high labor cost is that the industry is seasonal. The work is carried on not more than six months during the year and in some parts less. It seems that there are too many mines operating in the province. There are sufficient mines open and sufficient machinery to produce five times as much coal as will be mined this year. Last year 70 mines closed and 71 new ones were opened. The opening of new mines made the problem more difficult. With one-half of the mines in operation working a greater part of the season the situation would be much improved. It is difficult for the Government to prevent the opening of new mines, but unless something is done of that nature the coal industry of Canada will be in serious danger.

The state legislature effectively defeated the "coal bill" by forgetting it on second reading. The "coal bill" No. 204 provided that no municipal, county or state or other public office or institution should use other than Washington fuel. It was defeated when it first made its appearance but was resurrected the last week of the session for reconsideration.

Victoria, B. C.

"By bringing the coal-mining companies under the alternative of income tax or mineral tax, in common with other mining companies, we can hope for a revenue of $200,000 instead of the $160,000 estiated for the last year."

This statement was made by the Hon. John Hart, Minister of Finance in the British Columbia Government, when making his budget speech before the Provincial Legislature recently. It is of special interest to the coal operators of the Province as it intimates the policy on which the Government has determined relative to the taxation of the coal-mining industry. From the sense of the statement it is concluded that the report that a straight increase was to be made in the tax per ton of coal produced is without foundation.

In explanation it may be said that the tax the companies now pay is 10c. a ton. Returns of coal produced are made to the Government at regular intervals accompanied by taxation payments on the basis shown. Under the amendment which the budget speech of the Minister of Finance suggests, it is understood that this rate will stand, the companies paying as heretofore, but if at the end of the year it is found that tax on a company's income would realize more to the Treasury than has the 10c. a ton, the company will be required to pay the difference. In other words, the company will be taxed on whatever basis is found to bring in the greater amount to the public exchequer.

It must be understood that there is no definite assurance as yet that this is the Government's policy, because the bill amending the taxation act is not before the House up to the time of writing; but it is the only interpretation that can be placed on Mr. Hart's budget speech, and operators are satisfied that nothing further will be done this year. As far as can be gathered there is no particular objection to the proposal, though there would have been to any suggestion that the tax on the per-ton production be raised. The argument brought against such a move is that British Columbia coal to a large extent comes into competition with that of the Province of Alberta, and the coal of the latter Province is taxed only 5c. a ton.

PENNSYLVANIA

Anthracite

Minooka—The Carlton Coal Co. breaker was totally destroyed by fire on Mar. 19. The loss will exceed $50,000. The origin of the blaze still remains unknown. The structure was burned to the ground.

Pottsville—State Mine Inspector M. J. Brennan, of the nineteenth anthracite district, in his annual report to the state department of mines shows that last year influenza was far more deadly to mine workers than all the dangers of the mines. There were only 17 men killed in his district during 1918, but the Philadelphia &

Reading Coal and Iron Co., operating in the district, lost 118 men from the influenza. Pine Hill colliery lost 48, and Oak Hill 42. The Buck Run collieries lost 12 per cent. of its men from influenza and Darkwater colliery lost 14 per cent.

Scranton—Fire the night of Mar. 16 caused the destruction of the Minooka breaker of the Carlton Coal Co. It was one of the few electrically equipped breakers in this part of the anthracite field, and the loss is estimated at $50,000. Several hundred employees were thrown out of work. It is believed that crossed electric wires started the blaze.

Browndale—J. G. Westcott, of Endicott, N. Y., C. H. Truesdale and E. A. Wendell have purchased the Clinton Falls colliery. The purchase of the colliery includes a plot of ground containing 130 acres of coal land. The new owners are to take immediate possession. The machinery and the breaker on the tract have been leased to the company.

Jeddo—Returning to his home in New York, after an inspection of the G. B. Markle Co. properties, John Markle, president of the firm, announced that he will abandon his palatial summer residence and take out the rich beds of anthracite which underlie the premises, covering approximately 18 acres. The estate is one of the beauty spots of the Markle interests, and during the war was turned over to the miners and their families for the planting of gardens. The coal at this point forms one of the richest beds in the entire hard coal fields.

Reading—Engineers who completed an inspection of the Schuylkill Navigation Co. canal on Mar. 18 announced that there will be little or no coal boating on the stream between Port Clinton and Philadelphia next summer on account of the channel being filled with an unusual amount of coal dirt. The recent 7-ft. rise in the Schuylkill River, the largest of the winter, caused thousands of tons of coal dirt to be washed into the canal below Reading. It is explained that it would take an immense amount of dredging to clear the channel, and the navigation company does not seem inclined to go to the expense at this time.

Tamaqua—On Mar. 25 the Lehigh Coal and Navigation Co. put in operation its new No. 11 breaker in the Panther Creek. The breaker is of all-steel construction and is the finest and most modern in the southern anthracite fields. Heretofore it was necessary to send the product from the No. 11 workings to Hauto to be prepared for market, but the new structure will turn out the finished product ready for shipment, proving a great economy. The new breaker will have a capacity larger than the present supply calls for, as it is designed for future contingencies, when the output will be increased by the opening of additional workings.

BITUMINOUS

Canonsburg—A new tipple is to be erected at the Bridgeville mine, and a movement is on foot to organize a Boy Scout patrol.

Shenandoah—The Newly formed Raven Run Coal Co. has awarded a contract for a stripping at its colliery near here. A burning culm bank at this colliery has been successfully cut and the fire is under control.

Clymer—The Widdowson Coal Co. is constructing a new incline plane and storage bin just above its present tipple and will eliminate the long tram haul which it has had heretofore. The coal is loaded from the storage bin into the incline plane cars, which are of the large drop bottom monitor type car.

WEST VIRGINIA

MacCorkle—Under the direction of Samuel Butler, of Charleston, general manager, the Malleable Coal Co. is preparing to operate an additional mine which it is now opening at this place. The company is also erecting an up-to-date, well equipped tipple and intends to build two miles of standard-gage railroad.

Boomer—The No. 2 North mine of the Boomer Coal and Coke Co. broke all its previous records on Mar. 12 with an output of 1115 tons of coal. J. R. Huddy is the superintendent and C. E. Lilly the foreman. The company has been operating its mines on half time for a few weeks, but expects full-time operation in the near future.

Algonquin—The Algonquin Coal Co. has recently completed 20 new dwellings for the use of its employees.

Matoaka—The American Coal Co. has completed the tipple at the Piedmont mines, which will be used for dumping coal in cars provided by the Virginian R.R. The tipple tracks have not been laid as yet, having been held up on account of the war. It is expected the work will be commenced at once. When completed this mine will be able to load coal for shipment via both the New York & Western and Virginian railroads.

Matoaka—Representatives of the Consolidated Coal Co. were in this field looking over the properties of the American Coal Co. and subsidiary companies, with a view to purchasing. It is reported no agreement could be reached on price.

ILLINOIS

Niantic—Officers of the Niantic Coal Co. have under consideration the sinking of a shaft to a 7-ft. seam of coal which is believed to lie about 500 ft. beneath the surface. Coal is at present being mined from a 5-ft. seam at a depth of 365 feet.

Carlinville—Sixty-six men were employed the day the Berry mine operated. This is the first of the three new coal mines which the Standard Oil Co. is opening. More men will be taken on from time to time, and eventually 500 or more will be given work.

West Frankfort—It is said that many of the English and Italian miners in this vicinity are preparing to go back to Europe. The reasons assigned are the lack of work around the mines. Many of the Italian miners made such large wages during the war period that they can live at their ease in the villages of Italy for the rest of their lives.

Collinsville—At the Seventh subdistrict miners' convention here it was reported that there are now 65 coöperative stores in Illinois, organized by the miners. They are under the direction of the Central States Coöperative Society.

KENTUCKY

Whitesburg—The Wells-Elkhorn Coal Co., Beaver Creek, Ky., has purchased the plants and business of the Elkhorn-Black Diamond Coal Co. and the Salt Lick Coal Co., and has acquired additional holdings also—making this one of the largest in the new field. The capital of the company has been largely increased and some large extensions are planned for the immediate future.

Sergent—The Whitley Elkhorn Coal Co. has completed the installation of its power equipment, and plans some extensions and increases at once. Adam Q. Ramey is the electrical engineer.

Personals

H. A. Anderson has been promoted to the position of mine foreman for the Algonquin Coal Co., Algonquin, W. Va.

J. J. Maloney has been employed as a sales representative for the Goodman Manufacturing Co., of Pittsburgh, Penn., in the central Pennsylvania field.

Tom Cunningham has been engaged as mine foreman for the Pawama Coal and Coke Co., Matoaka, W. Va., vice **J. W. Shewsbury**, who has resigned to engage in other work at Roanoke, Va.

Joseph A. Graft, civil and mining engineer, has opened an office at 507 First National Bank Building, Connellsville, Penn. Mr. Graft until recently was superintendent of the Elkhorn Piney Mining Co., at Riley, W. Va.

F. W. Nay, well known among Kentucky coal operators of Clarksburg, W. Va., where for years he was connected with the Elkhorn Coal Corporation, has been transferred to Wayland, Ky., in the right Beaver Creek field of Kentucky.

G. M. Mathews, formerly manager of the Amburgy Coal Co., Smoot Creek, Ky., has accepted a position as superintendent of the Elkhorn Coal Corporation, Garrett, Ky., in the Beaver Creek field of Kentucky. He has entered upon his duties.

Roy Shirley, formerly coal inspector for the United States Fuel Administration in central Pennsylvania, has accepted a position with the Hulburt Oil and Grease Co., Inc., of Philadelphia. Mr. Shirley will make his headquarters in Punxsutawney, Penn.

Capt. A. C. Nell, construction division, United States Army, who for the period of the war has been in charge of the purchase of power and mechanical equipment in the construction division, has been released from active duty in the army and has been appointed Chicago district manager for the Lea-Courtenay Co. and the Schutte & Koerting Co. Mr. Nell was formerly connected with the Allis-Chalmers Manufacturing Co. The Chicago offices are at 1466 Conway Bldg.

Obituary

E. W. Bates, who has held the controlling interest in the Latham Mining Co., Lincoln, Ill., died Mar. 15 at Miami, Fla.

O. D. Maxwell, assistant superintendent of mines at Glace Bay, N. S., died Mar. 17 from heart failure. He was 50 years of age and had been an official of the coal company for 18 years.

Charles J. Wittenberg, president of the Wittenberg Coal Co., of New York City, died Wednesday, Mar. 19, in his fifty-fourth year. He was also president of the Newport News Docks and Coal Corporation, the Pocahontas and New River Coal Co., the Victoria Coal Mining Co., and the Virginia and Tidewater Coal Co.

John Patterson, mine foreman of the Klondike mine at Lilly, Penn., was killed recently when an unloaded mine car broke loose from a trip and ran down a grade, catching Mr. Patterson between the runaway car and a standing loaded car. He was fatally crushed and died on his way to the hospital. He was aged 50, and leaves a family.

John R. Williams, member of the once prominent bituminous company of Frank Williams & Co., now for some years out of business, died at his home in Buffalo on Mar. 18, at the age of 64 years. Since the dissolution of the company he had continued business in his own name, though quite out of health for some time. He was single. Three brothers, not in the coal business, and two sisters survive.

Coming Meetings

Illinois Mining Institute will hold its annual meeting May 22, 23 and 24. Secretary, Martin Bolt, Springfield, Ill.

National Coal Association will meet May 21, 22 and 23, at Congress Hotel, Chicago, Ill. Secretary, J. D. A. Morrow, Washington, D. C.

International Railway Fuel Association will hold its annual meeting May 19-22 at the Hotel Sherman, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

Indiana Retail Coal Merchants' Association will hold its annual spring meeting Apr. 23 and 24 at Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

Canadian Retail Coal Association will hold its fifteenth annual convention Apr. 2 and 3 at the King Edward Hotel, Toronto, Canada. Secretary, B. A. Caspell, Brantford, Canada.

Coal-Loading Shovel. W. Ferris, S. Bager and M. L. Fykse, assignors to Bucyrus Co., S. Milwaukee, Wis., 1,289,426. Dec. 31, 1918. Filed Apr. 28, 1917. Serial No. 165,215.

Publications Received

Methods of Shutting off Water in Oil and Gas Wells. By F. B. Tough. Bulletin 163, Petroleum Technology 46. Illustrated, 122 pp., 5¾ x 9 inches.

Biennial Report of the State of Nevada State Inspector of Mines, 1917-1918. A. J. Stinson, State Mine Inspector. Unillustrated, 97 pp., 6 x 9 inches.

Twentieth Annual Report of the Mining Industry of Idaho for the year 1918. Robert N. Bell, State Mine Inspector. Illustrated; pp. 133; 6 x 9 inches.

Abstracts of Current Decisions on Mines and Mining Reported from May to September, 1918. By J. W. Thompson, Department of the Interior, Bureau of Mines. Unillustrated, 138 pp., 6 x 9 inches.

Mines Producing Low-Sulphur Coal in the Central District. By Gilbert H. Cady. State of Illinois Department of Registration and Education, Division of the State Geological Survey. Cooperative Mining Series, Bulletin 23. Unillustrated, pp. 14, 6 x 9 inches.

The Quigley Powdered Fuel System. Quigley Furnace Specialties Co., Inc., New York, N. Y. Bulletin No. 11. Pp. 16, 8 x 11 in., illustrated. A system for preparing, transporting and burning powdered coal, lignite and peat that is the result of twenty years specializing in selection and application of fuels, and in furnace design, construction and operation.

Water-Gas Operating Methods with Central District Bituminous Coals as Generator Fuel. A Summary of Experiments on a Commercial Scale: a Preliminary Report. By W. A. Dunkley, State Geological Survey Division and W. W. Odell, U. S. Bureau of Mines. State of Illinois Department of Registration and Education, Division of the State Geological Survey. Cooperative Mining Series. Bulletin 24. Unillustrated, pp. 28, 6 x 9 inches.

Trade Catalogs

Leyner Oil Furnace No. 3. Ingersoll-Rand Co., New York, N. Y. Form No. 9120. Pp. 4, 6 x 9 in., illustrated. Catalog describing furnace used for heating drill steel.

United Hoists. United Iron Works Co., Kansas City, Mo. Catalog H-19. Pp. 76, 10¼ x 6¾ in., illustrated. Specifications of belt-driven, steam-driven electric-driven and horse and hand operated hoists.

Specifications of the Mancha Storage Battery Locomotive. Mancha Storage Battery Locomotive Co., St. Louis, Mo. Catalog. Pp. 4, 9 x 11 in., illustrated. Describes in detail the company's well-known types of haulage locomotives.

Fairmont Steel Tie. Fairmont Mining Machinery Co., Fairmont, W. Va. Pamphlet. Pp. 4, 6 x 9 in., illustrated. Gives the construction details of a steel mine tie that is being used in every coal-producing state in the Union.

Sullivan Small, Belt Driven Air Compressors.—Sullivan Machinery Co., Chicago, Ill. Bulletin 75-G. Pp. 12, 6x9 in., illustrated. Compressors described range from 50 to 470 cu. ft. in capacity. Simplicity, compactness, power, economy, a minimum of care and attention are claimed.

High-Tension Outdoor Universal "Unit Type" Bus Bar and Wiring Supports. Delta Star Electric Co., Chicago, Ill. Bulletin No. 34. Pp. 48, 8 x 10½ in., illustrated. Gives the design, adjustable features, prices and other details of bus bar and wiring supports for outdoor substations.

"Howells" Non-Corrosive Center Spads. Howells Mining Drill Co., Plymouth, Penn. Booklet. Pp. 6, 3⅝ x 5⅝ in., illustrated. Descriptive of mining engineer and surveyor's center spads made of copper, brass and galvanized sheet steel. Two pages are devoted to one of the Howells heavy geared post drill.

Perforated Metals. Hendrick Manufacturing Co., Carbondale, Penn. Catalog. Pp. 128, 6¼ x 9¼ in., illustrated. A beautifully printed book descriptive of this manufacturer's product, which includes perforated metals, elevator buckets (plain and perforated), conveyor trough and flights, stacks, tanks, hoppers, elevator casings and light structural steel work.

Automatic Reclosing Circuit Breakers. Automatic Reclosing Circuit Breaker Co., Columbus, Ohio. Bulletin No. 301. Pp. 4, 8½ x 11 in., illustrated. Describes the company's new type ARL, DRL and CRL breakers. These are automatic in operation and are governed by an index which responds only when load conditions are proper. The index is adjustable to suit any load condition.

No. 7 Deister-Overstrom Diagonal Deck Coal Washing Table. Deister Concentrator Co., Fort Wayne, Ind. Bulletin No. 2. Pp. 4, 9½ x 11½ in., illustrated. Among the advantages claimed for this process of washing bituminous coal are: Removes sulphur, reduces loss of combustible in ash, increases heating value, increases boiler efficiency, decreases transportation difficulties, makes marketable product from low-grade coal or screenings.

Catalog No. 17. Ohio Brass Co., Mansfield, Ohio. Pp. 671, 6¼ x 9¼ in., illustrated. A comprehensive publication, carefully indexed and divided into department classifications for ready reference. Should be on the desk of any purchasing agent interested in appliances used in mine haulage systems and transmission lines. Among the specialties listed are high tension porcelain insulators, overhead materials, rail bonds and car equipment.

Industrial News

Ashland, Ky.—The Lackey Mining Co. has increased its capital stock from $12,000 to $25,000.

Mossy Bottom, Ky.—The Kentucky Block Fuel Co. has increased its capital stock from $100,000 to $200,000.

Akron, Ohio—The authorized capital of the Akron-Virginia Coal Co. has been increased from $10,000 to $250,000.

Ashland, Ky.—The Sandy & Guyan Coal Co., capital $20,000, has been incorporated by H. C. Rogers, V. I. Jones, O. D. Jones, and others.

Indianapolis, Ind.—The J. R. Morris Coal Co. has filed notice of an increase in its capitalization from $30,000 to $60,000, to provide for expansion.

Richmond, Ky.—The Savage-Smith Lumber and Coal Co., Richmond, capital $20,000, has been incorporated by Earl Savage, William Smith and D. C. Field.

Cincinnati, Ohio—The Kellicka Coal Co. has been chartered with a capital of $100,000 by Edward F. Peters, Frank E. Burnett, S. Geismar, S. R. Ducker and J. G. De Fossett.

Scranton, Penn.—The Echo Coal Co. has been incorporated with a capital of $50,000 to engage in general coal-mining operations. E. A. Gallagher is the principal incorporator.

Ebensburg, Penn.—The Cambria Fuel Co. has been incorporated with a capital of $100,000 to operate in the Ebensburg district. A. W. Evans and associates are the incorporators.

Cleveland, Ohio—The Lake and Rail Coal Co. has been chartered with a capital of $10,000 by Edwin Robbins Smead, Marie O. Smead, Alice I. Lane, Rudolph Krause and Henry Grund.

Sullivan, Ind.—The Black Comet Coal Mining Co. has filed notice with the Secretary of State of an increase in its capitalization from $100,000 to $135,000, to provide for expansion.

Lock Haven, Penn.—The Lock Haven Mining Co. has filed articles of incorporation with a capital of $100,000, to operate in the Lock Haven section. C. F. Kreamer is the principal incorporator.

Knoxville, Tenn.—The Calvin Holmes Coal Co., has recently filed notice with the Secretary of State of an increase in its capitalization from $100,000 to $150,000, to provide for general business expansion.

Morgantown, W. Va.—The Adams Coal Co. has filed articles of incorporation with a capital of $25,000 to engage in coal-mining operations in the Morgantown district. John A. Adams is the principal incorporator.

Ashland, Ky.—The Sandy & Guyan Coal Co. has been incorporated with a capital of $20,000 to engage in general coal-mining operations in the Ashland section. V. I. and O. D. Jones and H. C. Rogers are the incorporators.

Cincinnati, Ohio—The Kellicka Coal Co. has been organized by local financial interests, with a capital stock of $100,000, being a reorganization of the old Kellicka Coal Mining and Sales Co., operating in Harlan County, Kentucky. L. E. Armen-

Lexington, Ky.—The Vesper Coal Mining Co. has opened offices in Dallas, Texas, with J. K. Bowering as agent in charge of their Texas business. This company owns leases on a large area of west Texas coal lands which it is planned to develop at an early date.

Petros, Tenn.—The State Board of Control, Nashville, John S. Denton, chairman, is arranging plans for the immediate reconstruction of the tipple at its Brushy Mountain coal-mining properties recently destroyed by fire with loss estimated at $10,000.

Pittsburgh, Penn.—The Consumers' Fuel Co. has contracted with the Roberts & Schaefer Co., of Chicago, for the installation of a picking table in connection with its tipple at the Eureka mine. The new equipment will be installed within the next sixty days.

San Angelo, Tex.—The West Texas Coal Mining and Developing Co. is arranging plans for the early development of approximately 585 acres of coal properties. Mining machinery for all details of production will be installed. J. W. Powell, Ballinger, Tex., is president.

Jellico, Tenn.—The Italian Coal Co., recently incorporated with a capital of $50,000 to operate in the Jellico district, has arranged plans for the development of a tract of about 5000 acres of coal properties. It is understood that work will be inaugurated at an early date.

Evansville, Ind.—The Evansville Atomized Fuel Co. has been incorporated with a capital of $250,000 to manufacture atomized fuel in Vanderburg County. Fred Amann, John J. Tuite, William E. Tuite, Thomas Lavelle and Norman Patrick, Indianapolis, are the incorporators.

Jellico, Tenn.—The Italian Coal Co., recently incorporated with a capital of $50,000, has plans for development of 5000 acres of coal land, but has not completed plans relative to production and time for starting development. C. O. Baird, E. S. Miller and Z. D. Baird are the principals.

Whitesburg, Ky.—The Wells-Elkhorn Coal Co. has increased its capital stock from $75,000 to $300,000, after leasing about 1500 acres of coal land in the Jack's Creek section. The company has its office at Left Beaver Creek. A new town will probably be built at the site of the proposed mine.

Whiteside, Tenn.—The New Etna Coal and Lumber Co. has been organized by J. C. Higdon, president; Van Eastland, secretary, and others, to develop a 200-ton daily production. The company will also handle lumber, ties and forest products. Company is capitalized at $30,000 and has equipped mines.

Phoenix, Ariz.—The Olmos Coal Mining Co. of Phoenix, Ariz., has been granted a permit to do business in Texas, employing a capital stock of $400,000. Texas headquarters will be maintained at Eagle Pass, and the company will develop extensive holdings of coal lands in the border country of Texas.

Whiteside, Tenn.—The New Etna Coal and Lumber Co., recently incorporated with a capital of $30,000, has perfected its organization and is arranging plans for the development of local properties, to have a daily capacity of about 200 tons for initial operations. J. C. Higdon is president, V. Eastland is secretary.

Whitesburg, Ky.—The Wells-Elkhorn Coal Co., a new corporation at Left Beaver Creek, north of Whitesburg, has increased its capital from $75,000 to $30,000, after leasing 1500 acres of coal lands in the Jack's Creek section. The company plans big developments and a new mining town when conditions are right.

Washington, D. C.—In a tentative decision rendered by the attorney examiner of the Interstate Commerce Commission, joint rates on coal from Illinois and Indiana mines, allowing a charge to St. Louis of 20c. higher than that to East St. Louis, due to river transportation across the Mississippi River, have been upheld.

Gadsden, Ala.—The Blount Mountain Coal and Iron Co. has filed articles of incorporation, capital stock being named as $2000. J. J. Burns, of Chicago, is president of the company and D. E. Mitchell, of Gadsden, is the local agent of the corporation. It is understood that the company has about 30,000 acres of coal land under option.

Dayton, Ohio—The Robert H. Ball Coal Co., recently chartered with a capital of $150,000, will soon start development of a large area in the Hazard field of Kentucky. It is also announced by Robert Ball, president, that the concern will build a large coal elevator in its retail yard in the east side of Dayton at a cost of approximately $20,000.

Scranton, Penn.—H. McKean Conner, consulting mining engineer, has received the drawings for a complete coal mining plant to be built in South Brazil, the expected output to be 1000 tons in eight hours. The shaft is 131 meters deep. The equipment, which has all been bought in the United States, is up to date in every particular.

Radford, Va.—The Belle Hampton Coal Co., recently incorporated, has completed negotiations for the purchase of the Belle Hampton coal properties, and it is understood that plans are now in process of formation for the commencement of development at an early date. It is said that the plans include the construction of necessary railroad facilities.

Chicago, Ill.—The first concrete coal car ever constructed was recently delivered to the Illinois Central R. R. for operation in the company's coal service. The patentee and designer is Joseph B. Strauss, civil engineer and president of the Strauss Bascule Bridge Co. The car has a capacity of 100,000 lb. and was built by the Conway Co., a Chicago concern.

Columbus, Ohio—The Flint Coal Co. has been chartered with a capital of $40,000 to operate a coal mine near McArthur. The mine has been opened and is loading some coal. It is planned to increase the output. William Dauch, of Delphos, Ohio, is president; W. C. Fridley, Lima, vice president, and L. F. Bertram, Columbus, secretary, treasurer and general manager.

Chicago, Ill.—The W. A. Jones Foundry and Machine Co., manufacturer of a complete line of power transmission apparatus, special foundry and machine work and also the Jones spur gear speed Reducer, has opened an eastern office at 30 Church St., New York, under the direction of Lemuel C. Biglow, who formerly for a number of years held a similar position with the Morse Chain Co., of Ithaca, N. Y.

New York, N. Y.—The St. George Coal Co. is the name of a new corporation with offices in the Singer Building, 149 Broadway, this city. G. B. St. George is the president and L. V. Bermingham is vice-president. Mr. Bermingham was formerly a salesman for Whitney & Kemmerer. This company will handle Philadelphia & Reading; Delaware, Lackawanna & Western and Lehigh Valley Coal Co.'s coals.

Clarksburg, W. Va.—One of the new and larger corporations of the state organized within the last few days insofar as securing a charter was concerned, is the Orr Coal Co., with a capital of $100,000, the company being interested in the operation of several large plants in northern West Virginia. Leading figures in the new company are Harry W. Sheets, J. W. Agnew, C. S. Elliott, C. E. Prunty and J. W. Booth, all of Clarksburg.

Chicago, Ill.—The Sullivan Machinery Co. announces the appointment of Chester Mott as manager of its branch office at Denver, Colo., 837 Equitable Building, succeeding Wallace T. Roberts, recently resigned. Mr. Mott has been associated with the company for several years past in the capacity of sales engineer at its Spokane, Wash., office and more recently at its Chicago office in charge of the company's interests in Iowa, Northern Illinois and Minnesota.

Dallas, Tex.—The Garrison Coal and Oil Co. is being organized here for the purpose of developing a tract of 500 acres of land underlaid with lignite. This tract of land is near Garrison, Texas, and is also considered as promising for oil development. The company is capitalized at $500,000 and the officers are: Sterling P. Strong, of Dallas, president; T. R. McLean, of Mount Pleasant; L. E. Birdsong, of Greenville; J. R. Slay, of Frost; R. W. Caraway, of Logansport, La.; and W. Y. Garrison, of Garrison, directors.

Benton, Ill.—The Dodds Coal Co., with a paid-up capital of $25,000, has been incorporated by the Illinois secretary of state. It has its principal office at Carrier Mills, Saline County, Illinois. The company has secured a large tract of land just southeast of Carrier Mills for prospecting. The Big Four R.R. has a switch leading to the mine. The vein of coal is said to be large and the quality unsurpassed. Coal has been lifted during the past few months from the air shaft, but the main shaft is to be completed within a few weeks.

Charleston, W. Va.—Under the terms of a bill introduced in the Senate of the West Virginia legislature, now in extraordinary session, by Senator E. H. Morton, of Webster Springs, no company, firm or person shall operate a mine after June 1, 1919, unless a license shall have first been secured; and to secure such a license application would have to be made to the auditor of the state, together with a written statement swearing to the production of each mine of the applicant.

Charleston, W. Va.—In all 33 lives were lost during the month of February in West Virginia mines, 21 fatalities alone being due to falls of coal, slate, roof, etc. The next largest number of casualties—seven—was due to mine-car accidents. Only two deaths were caused by motor accidents. The only other fatality within the mines was caused by an electrical shock. There were, however, two deaths on the outside of the mines, one due to electricity and the other resulting from a motor-car accident. Of th total number of 33 fatalities, 11 were in McDowell County.

Columbus, Ohio—President Henry A. Williams and Secretary James T. Daniels, of the Columbus Chamber of Commerce, have suggested a central route for the proposed barge canal to connect the Ohio River with Lake Erie. In the authority secured from Congress for a survey the route from Cincinnati to Toledo by way of the Miami canal is expressly mentioned, but authority is given for the survey of "other practicable routes." Now it is proposed to have the route from Columbus to Sandusky via the Scioto River to Marion and the Sandusky River from Upper Sandusky to Sandusky surveyed also.

Danville, Ill.—The Illinois Traction System has been ordered by the Council of Danville, Ill., to cease hauling coal through the streets between the hours of 6 a.m. and midnight. During the period of the war the demand for coal became so urgent and the difficulties of transportation so great that the Councils of Danville, Champaign, Urbana and other cities modified their pre-war ruling that no interurban trains of coal could be moved through the streets between the hours of 6 a.m. and midnight. The Danville Council now demands that coal cars be transported through the streets of the city only during the latter part of the night, that is from midnight to 6 a.m.

Gary, Ind.—About 5000 tons of coal, originally purchased by the Aetna Explosive Works for the purpose of making munitions, have been purchased by the Gary board of education. James F. Cullerton, purchasing agent of the school system, bought the coal through the Empire Trust Co., receivers for the Aetna company. The coal was the property of the French Government, which made its purchases through the Aetna company. Mr. Cullerton purchased 2000 tons at $1 a ton and learning that 3000 tons were still in the bunkers, telegraphed an offer and it was immediately accepted. Mr. Cullerton made a large saving for the board of education, the supply of coal being enough to last the Gary schools one year.

Louisville, Ky.—Further warnings on the part of western Kentucky mine workers to some of the operators who are cutting coal prices, or who are threatening to make reductions, have been sent out by unions representing the men. Serious conditions are said to be impending unless the workers are heeded. The latest ultimatum is from District Union No. 23, United Mine Workers of America, with headquarters in Kentucky and is addressed to western Kentucky operators in general. The miners claim that the only meaning of reduced prices is reduced wages. The ultimatum recites that the coal miners need more than a mere living, in fact a profit on their work, and emphasizes the fact that the coal miner has done a large part in the industrial background of the recent world war.

Baltimore, Md.—The annual meeting of stockholders of the Consolidation Coal Co. held here recently brought with it the retirement from its presidency of Jere M. Wheelwright, who will, however, take up the work incident to the post of chairman of the board of directors. Former Senator Clarence Watson, who has been chairman of the board, became president of the company. New vice-presidents named are Sprigg D. Camden, of Parkersburg, W. Va.; F. W. Wilshire, of New York; and E. M. Mancourt, of Detroit. Arthur Hale was reëlected vice president. George T. Watson and Fairfax S. Landstreet are named as assistants to the president. New directors on the board are Gen. Carl R. Gray, Brooks Fleming, Jr., and George T. Watson. The net tonnage of the Consolidation mines in 1918 was 8,053,010, as against 9,533,543 tons the year previous. The net earnings of $26,148,895 showed only a decrease of $35,691, but the net earnings of $7,155,169, because of labor and other operating increases in cost, showed a falling off of $4,181,791.

St. Louis, Mo.—Following the submission of a tentative report to the Interstate Commerce Commission by Commissioner Mackley upholding the Terminal Railway Association's bridge arbitrary of 20c. a ton on coal, bills have been introduced in the Legislature authorizing the city to create and operate its own terminals. It is planned to establish such terminals in competition with the Terminal Railway Association if the Interstate Commerce Commission upholds Mackley's report. It is the intention to use the municipal free bridge, city terminal property and the Manufacturers' Ry. It is also contemplated to appeal the case to the Federal Court, if the decision of the Commission is adverse to the city. The appeal will be in the form of contempt proceedings against the railroads in the Terminal combine to compel them to show cause why they treat the Terminal as a separate road and allow it a separate rate for carrying coal and other freight across the river to St. Louis and performing a delivery function which the roads themselves should perform.

Weekly Review

Labor's Attitude When Peace Is Signed Now Chief Topic of Discussion—Now Is Best Time to Purchase Fuel—Consumer Shares Blame in Present Coal Situation—Anthracite Industry Dull—Contract Inquiry Brisk

UPPERMOST in the minds of the thinking element in the bituminous coal industry is the question of what turn events will take when the present wage agreement expires, which will be when the treaty of peace is signed. To say that the mine workers are restive is to put it mildly. The men are dissatisfied with their present earnings and with their hours of work, and have already gone on record as demanding a six-hour workday for only five days a week and an increase in the daily rate. This would net them more return for the reduced working time than they receive for a full 48-hour week under the present agreement.

These demands, in the main, are the result of the reduced working time at the mines, though one cannot overlook the fact that they are also a reflex of the attitude now being taken by British mine labor. The tremendous cut in coal consumption in this country immediately following the signing of the armistice led to the shutting down of a large number of operations and the curtailment of working time at many others. The story has been told so often that it has become almost a platitude.

What the large consumer of coal does not realize, however—and what he will be the first to deny—is that he himself cannot escape blame for the present situation. He kept out of the market for so long a period that his disinterestedness has shaped itself into a boomerang that has turned the corner and will shortly strike him in his most vulnerable spot—his pocketbook. For, if the miners' demands are satisfied, it will mean an increase of more than 60 per cent. in the earnings of mine workers who are paid by the day. Other classes of labor will doubtless want increases, and all in all the cost of producing bituminous coal will be much higher. This certainly is pathetic, as the chief reason that prompted most consumers to hold off in their buying was that prices must certainly come down.

Once the situation is viewed in its true light, apathetic purchasing agents will awaken to the fact that the time to buy coal and make contracts for their future requirements is right now. The Federal Fuel Administration has already seen the handwriting on the wall, and is urging consumers to buy soft coal early. This is not another unfounded cry of "Wolf! Wolf!" but is based on the production figures of weekly coal output. During the week ended Mar. 31 the output of bituminous coal was 8,065,000 net tons. At this rate the production at the end of the present coal year will not exceed that of the previous coal year by more than 8,000,000 net tons.

The anthracite situation is exceedingly dull. What the labor attitude will be when peace is signed it is hard to foretell, as the workers in the hard-coal region have a contract that does not expire until 1920. However, we have heard references made somewhere to "scraps of paper." Agreements and treaties in these momentous days seem to carry with them no particular significance.

A reduction recently made in the price of rice and barley may help to stimulate interest in these two steam sizes of anthracite. Dealers are not stocking up to any extent, believing that it would be wiser instead to dispose of the stocks on hand. Production is picking up somewhat, the output of hard coal during the week ended Mar. 15 being estimated at 1,206,000 net tons. The total production for the coal year to Mar. 15 is 89,317,000 net tons, as compared with 95,370,000 net tons during the same period of the previous year.

Contract activity in the bituminous industry is brisk, though operators are loath to bind themselves at this time as they do not know what the labor situation will be two months from now. Prices are being maintained, the better grade coals finding ready takers at former Government figures. Low-grade coals are hard to move. Conditions in the bituminous trade are improving, though many operations are still working short time due to "no market."

WEEKLY COAL PRODUCTION

The production of bituminous coal during the past few weeks has varied but very little, and the current week's output, estimated at 8,065,000 net tons, is no doubt a fair barometer of bituminous coal demand. As during recent weeks, the current week's output fell approximately 3,000,000 net tons below the production for the same week of 1918, bringing the excess in the output for the coal year to date over the same period of last year down to 13,670,000 net tons, and it is estimated that the close of the coal year on Mar. 31 will find the excess at not more than 8,000,000 net tons, and the actual output at approximately 558,000,000 net tons for the year. The daily average per working day during the week ended Mar. 15 is estimated at 1,344,000 net tons, as against 1,806,000 net tons for this coal year to date, and 1,760,000 net tons for that period of the 1918 coal year ending with Mar. 16.

Production of anthracite in the United States during the week ended Mar. 15, estimated at 1,206,000 net tons, was approximately 20 per cent. in excess of production during the week ended Mar. 8, estimated at 989,000 net tons. Compared with the production during the week ended Mar. 16, 1918, when the output was 2,099,000 net tons, the current week's production was exceedingly low. The daily average per working day during the week ended Mar. 15, is estimated at 201,000 net tons, as against 298,000 net tons for the coal year to date, and 318,000 net tons for the same period ended Mar. 16, 1918. Total production for the period Apr. 1, 1918, to Mar. 15, 1919, is estimated at 89,317,000 net tons, as compared with 95,370,000 net tons during the same period of last year.

Carriers' reports for the week ended Mar. 15 show but few changes in loading in the various fields, compared with the week to Mar. 8. Slight decreases occurred in Pennsylvania, Tennessee and Kentucky, and in the central states, while slight improvement was reported in all other fields. For the calendar year to date, loading in all the fields is considerably behind that of last year.

The mines of the country have been operated during the past four weeks at approximately 50 per cent. of their full time, with time losses due to labor and car shortage, mine disability and lack of market, fluctuating but very little from week to week. The real limiting factor is, of course, lack of demand, and unless the "buy early" campaign, inaugurated by the United States Fuel Administration during the past week, is taken seriously by the consumers of the country, very little improvement may be expected in the full-time operation of the mines until the stocks accumulated last summer and fall are more generally used up.

Tidewater shipments to New England during the week ended Mar. 15, are estimated at 57,710 net tons, and are 48.2 per cent. behind shipments during the week of Mar. 8. No tonnage was loaded at Baltimore for New England, while the tonnage loaded at New York and Philadelphia, amounting to 34,156 tons, fell 47 per cent. behind the loading of the week preceding, and Hampton Roads tonnage of 53,554 net tons fell 49 per cent. behind. Rail shipments during the week to New England were not reported.

Shipments of bituminous coal from North Atlantic ports and Hampton Roads to all points, during the week ended Mar. 15, are estimated at 321,064 net tons, and are 29.4 per cent. behind shipments during the week preceding. Baltimore, with a loading of 35,069 net tons, was the lone harbor to report improvements, the current week's shipments exceeding that of the preceding week by 57.7 per cent. Shipments from New York and Philadelphia during the week of Mar. 15, fell 48.1 per cent., and from Hampton Roads 19.4 per cent.

Beehive-coke production in the United States during the week ended Mar. 15 is estimated at 429,446 net tons, as against 441,031 net tons during the week of Mar. 8, and 604,516 net tons during the corresponding week of last year. The daily average per working day during the current week is estimated at 71,574 net tons.

and while slightly in excess of the daily average for the calendar year to date, estimated at 70,402 net tons, is considerably below the daily average for the same period of 1918, estimated at 79,312 net tons. Production during the current week in Pennsylvania, Virginia, Kentucky and the far west states fell below that of the week of Mar. 8, while considerable improvement occurred in West Virginia, Alabama, Tennessee and Georgia. Compared with the week of Mar. 15, 1918, the current week's production in all states is exceedingly low.

BUSINESS OPINIONS

Bradstreet's—Trade and industrial developments of the week have been many and varied, these including a further expansion in spring trade at most markets, especially in dry goods and wearing apparel, hitherto inclined to lag a trifle behind other lines; a speeding up of industrial operations where readjustments have been completed and new demand has appeared; a glowing series of reports as to early crop and soil conditions in surplus crop regions; a rather sharp advance in many food products, with a consequent advance in the general level of necessaries; excellent returns as to general export trade for February, and enlarged shipments of wheat to Europe.

Marshall Field & Co.—Current wholesale distribution of drygoods is running considerably less than for the same week of 1918. Road sales for both immediate and future delivery also were much less than the high figures of a year ago, although first fall orders for lines which have just been opened are larger in comparison with those of last year. More customers were in the market. Collections continue satisfactory.

Dry Goods Economist—In the great agricultural region west of Chicago retailers are doing a large business. Naturally, in the industrial centers where there has been cessation of Government work, or labor unrest, retailing has been on a somewhat less free scale. Such conditions, however, are the exception. For Southern retailers there has been encouragement in the renewed upward movement of cotton.

American Wool and Cotton Reporter—The feeling in the wool market is improving generally. Demand is, however, a little spotty. Some days the demand is marked and some days it is not so pronounced. China wools are of interest for woolen purposes, and fine wools are also in demand. There is some talk of the United States Government following the ideas of the British government in reducing the price levels. Dealers are naturally laying their plans for purchases of the next clip, and they do not want to make them at the present level, if the Government is going to reduce prices. Tendencies in the cotton market are bullish. Predictions are made in many quarters that raw cotton will sell at materially higher prices before a new crop is marketed.

The Iron Age—Among the leading producers of steel there has been no change in the feeling that price reductions at this time will not produce the desired revival in buying. Reductions in copper, more drastic than have been proposed in steel, have not stimulated demand, it is argued; and the spelter market, with the price below the cost of well-equipped producers, has no semblance of life. The amount of steel bridge and building work put under contract in February was practically no greater than that in January. The total of the two months is 44,000 tons out of a year's capacity of 2,160,000 tons. In the winter of 1914-1915, before the war demand from Europe set in and when the fabricated steel business saw the lowest demand for years, the January-February total was about 95,000 tons, more than twice this year's.

Atlantic Seaboard

BOSTON

Another pause in buying. Many contracts made for small tonnages. No comprehensive buying as yet. Quotations firm. Few consumers can take April or May coal. Diffident about contracting. Wide range in price continues. Hampton Roads freights approach stable figure. June is the earliest date set for buying Southern coals. Distress offerings at New York piers. Anthracite quiet. Railroad-owned barges tied up generally. Effort made to induce retail buying, but demand extremely light. Steam sizes in short supply.

Bituminous—For the first time since the market began to improve a month or so ago there is now an interval of very few purchases. It is not due to any slackening in interest, nor can it be regarded in any sense as a sign of weakness; it simply means that those who were ready to buy have done so, and that others have postponed entering the market. There is bound to be a dull period between now and a month or two hence when it is expected there will be renewed inquiry and on a larger scale. Those who can take in during the summer what is practically a season's supply are still waiting to test the market, and this attitude will be justified so long as operators make spot prices less than their contract offerings. The crux of the matter is, however, that there are few large consumers in position today to receive shipments in such volume as would be of help to producers who are struggling to hold their men at the mines.

While the number of contracts already placed is large, and the aggregate tonnage considerable, it should be stated that most of them are for less than 10,000 tons and that with few exceptions they are on grades that have come to be regarded as specialties. Nothing else would account for the prices consumers have agreed to pay. And it is also true that by far the greater number of these contract arrangements have been made in the same channels as in other years. Service during 1917 and 1918 has frequently been a consideration in favoring customary sources of supply, but now most of this smaller business has been taken care of and there remains the broad competitive market the trade is hoping for later in the season.

Several charters have been made from Hampton Roads to Boston at $2, but there is only light demand even at that figure. The trade regards this as about the right level for barge transportation, although on steamers it is felt that when several of the 5000 to 8000-ton ships are returned by the Shipping Board to their owners, there will be a rate nearer $1.50@1.75. It is expected that by June 1 Hampton Roads rates will have become stabilized and that the smokeless agencies will be in that much better position to make delivered prices.

No one here looks for any active market on Pocahontas and New River until well into June and July. Of course a considerable volume of business has already been underwritten by factors who are themselves producers, but this is all on a mine basis plus charges. Inland from Providence and Boston buyers are more likely to wait for a definite figure on cars; otherwise they will turn to all-rail shippers. It seems to be clearly established that a large number of buyers who have been accustomed to Southern coals will pay a dollar or more over the cost of all but the very choicest grades from Pennsylvania.

One of the demoralizing features of the present situation is the volume of distress coal available at the New York piers. This is being sold at from 50c. to 75c. less than any $2.95 price at the mines would warrant and the few orders that were in the market for April shipment have been filled from that source. With small barges plentiful at $1.35 from New York to Boston it is easy to see that this coal would be readily absorbed by consumers who had the room to take it. Buyers find it hard to understand why prices should be held so firmly at the mines while sacrifices are being made at the loading ports.

Bituminous prices at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net ton as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.80@3.50
Philadelphia, gross tons	4.20@4.90	5.00@5.55
New York, gross tons	4.50@5.25	5.35@5.95
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.80

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.70@5.25 f.o.b. Norfolk and Newport News, Va., for spot coal, the former Governmental differential of 35c. in favor of New River being fairly well maintained. Alongside Boston the present gross ton range would be $7.15@8.10.

Anthracite—Demand remains extremely quiet, the kind of market that usually precedes a 50c. reduction in price. While retail dealers along the coast have no expectations of lower prices on coal they are certainly withholding orders until something definite is announced with regard to barge rates. Only in scattered instances, however, are all-rail dealers filing their orders for April shipment. A 15c. advance is certain for May 1, and yet there is no buying in any direction worth talking about. In any other year this lack of interest would be something remarkable.

A large fleet of railroad-owned barges and tugs is tied up at New York because the authorities have not yet seen fit to fix lower rates. Outside barges are in ample supply at $1 to ports on Long Island Sound and at $1.25@1.35 to Boston. The few cargoes of domestic sizes now coming forward are being freighted in these boats and the trade is eagerly waiting for some sign from Washington that railroad barges will resume their usual functions in the anthracite business. Meanwhile the piers at Philadelphia and New York are embargoed from further receipts because of accumulation, and collieries are forced to shut down three and four days a week.

NEW YORK

Reduction in prices for rice and barley announced by one of the large companies. Harbor strike ties up shipments and supplies are running short. Public service corporations are feeling effects of labor trouble. Line dealers taking coal and active market expected. Policy of education may help summer buying. Bituminous situation shows slow but steady improvement. Dumpings of anthracite and bituminous increase.

Anthracite—The announcement of one of the large producers of a 15c. reduction in the prices for rice and barley was by far the best information received by the trade the past week. A cut in the mine prices for the anthracite steam sizes has been hinted at for some time as the only way of holding the present trade and also as a means of regaining some of the trade lost to soft coal operators because of the lower prices at which bituminous could be obtained. With the cut in rice and barley prices the present rates at the mines are $2.75 for rice and $2.25 for barley. There was no cut made in buckwheat.

There is a good demand for the steam coals which enables the companies to maintain prices and put a premium on some grades of the so-called independent product, especially the better grades. Stocks are not plentiful because of the curtailed production, but there is enough to keep everybody supplied with current requirements.

Movement of the domestic coals, as well as of the smaller sizes, has been slow because of the harbor strike now in its fourth week. Very little coal has left the docks, but this has not as yet inconvenienced the local retail dealers to any great extent, most of whom had full bins when the difficulty first started. Their bins are now beginning to look rather bare, but no serious consequences are looked for so long as weather conditions remain seasonable.

Most Brooklyn and Long Island dealers have been kept supplied with coal because of all-rail deliveries. The office buildings in lower Manhattan are not having any difficulty in keeping their fires going, most of this fuel being ferried across the river from the New Jersey pockets.

Some houses report fairly active buying inland with good prospects for the late spring and summer. It is expected that considerable coal will be sent into the west, many inquiries having been received from that section of the country.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	5.85	7.70
Stove	6.10	7.95
Chestnut	6.20	8.05
Pea	4.80	6.55
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The slow but steady improvement continues. Operators say that inquiries are more numerous and that the prospects of a good contract closing are encouraging. In some instances it is said the operators are inclined to hold back, they not being disposed to tie up the major part of their output.

The marine strike is playing havoc with consumers, not many of whom can boast of large stocks at present. With the trouble entering upon its fourth week and the settlement apparently as far off as at any time, the outlook is dubious for many industrial plants that secure their coal by water. Already many large consumers are canvassing the situation and making arrangements, if it is possible, to secure sufficient coal to meet their current needs.

Shipping has also been interfered with and many bottoms have been sent to other ports because of the difficulty to obtain

fuel here. In many instances transatlantic liners have been detained for a couple of days while waiting for sufficient coal to take them to Europe. This has caused a considerable loss of tonnage to local dealers.

There is an increasing call for coal along the line, but in small lots, the tendency apparently being to prevent having large stocks on hand as the heated season opens. There is also a feeling that buying can be done at lower prices as the season advances, but operators ridicule that idea in the face of the present cost of mining.

The poorer grades of coal are not being inquired about, buyers wanting nothing but the high-grade coals. While the appended price list gives the average range of quotations, some lower quotations have been heard of for various grades of coal:

Quotations in various grades of bituminous coal for spot delivery and contract follow:

	Spot	Contract
South Forks	$2.90 to $3.50	$2.95 to $3.50
Cambria County (good grades)	2.80 to 3.10	2.95 to 3.10
Clearfield County (good grades)	2.65 to 2.95	2.80 to 2.95
Reynoldsville	2.65 to 2.95	2.85 to 3.00
Quemahoning	2.85 to 3.10	2.95 to 3.10
Somerset County (best grades)	2.80 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.50 to 2.75	2.75 to 2.95
Western Maryland	2.50 to 2.75	2.65 to 2.85
Fairmont	2.10 to 2.35	2.35 to 2.50
Latrobe	2.25 to 2.40	.....
Greensburg	2.35 to 2.40	2.35 to 2.60
Westmoreland ¼-in.	2.60 to 2.75	2.65 to 2.75
Westmoreland run-of-mine	2.40 to 2.65	2.40 to 2.65

PHILADELPHIA

Improvement in anthracite situation checked by state price inquiry. Consumers withhold orders expecting lower prices. Retail price cutting minimized. Pea size hangs heavily on shippers. Stove and nut in most demand. Contracting on steam sizes. Bituminous quiet. Prices well maintained, with light production. Contracting increases. Railroads buying little fuel until April 1.

Anthracite—As the dealers were preparing to go after spring business following the announcement of the summer price schedule, Governor Sproul announced his intention of investigating the reason for the continuation of the winter schedule. The newspapers have given wide publicity to the subject, and this has had quite a distressing effect on business.

Any investigation honestly undertaken will only divulge what every other similar query has shown during the past several years—that the retail price of coal per ton has advanced far less in proportion than most commodities. As a matter of fact it would not be surprising if the investigation should demonstrate that an even higher price is justified.

In the meantime the coal trade has sagged almost completely. Retailers report that many customers who had placed orders for spring delivery have telephoned in suggesting that these be held until later in the season, frankly stating that they feel coal might be lower in price. This seems to be the general impression.

Shippers report that little business is being received without solicitation. Even where dealers have room for a considerable tonnage they are in no hurry to buy, and all seem satisfied they can secure their requirements during April.

There is little price-cutting, what there is of it being confined to the firms who usually indulge in this game. So far as we can learn the principal efforts of the price cutters have been centered on pea coal, which nearly every one has in stock in large volume. The lowest price on this size remains at $8, and one dealer has cut as low as $10 on egg.

Pea coal continues to be a burden on the shippers. It was really a surprise when the new prices were announced that some action was not taken to make it more attractive. It is a fact that some shippers have changed their screens and a better size is coming to market, but the price is too near that of chestnut to attract the consumer; as a consequence sales are away below normal for this time of year. Chestnut is beyond all doubt the best seller now, and with stove is causing much less trouble than the other sizes. Owing to the mild winter, egg coal, which usually had quite a spurt late in the season because the early supplies of the householders had become exhausted, has recently been draggy. We hear of some price cutting on it by the smaller houses. This condition will probably not be general after Apr. 1, as we expect to see egg as well as broken well covered by contract. At this time one of the large operating companies is entering into agreements on broken at $5.95 at the mines, which is also the present circular on that size, and while egg coal is $5.85 and will so continue until May 1, will eventually be 40c. higher than broken.

Among the steam coals buckwheat is being sold off by some of the independents, but not in very large lots. All the larger shippers are adhering strictly to the price of $3.40, as recently announced, and are making contracts on that basis. On the smaller sizes there have been slight price reductions by the companies, amounting to 15c. per ton.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	5.85	7.70	Rice	2.75	3.65
Stove	6.10	7.95	Boiler	2.50	3.50
Nut	6.20	8.05	Barley	2.25	3.15
Pea	4.80	6.40			

Bituminous—The trade continues as it has for the past ten weeks. There is little buying for current use, yet the operators are able to maintain the price range on good coals from $2.90 to $3.15. Rather than sell below these figures many operators close down their operations. On special coals, such as blacksmith, prices run from $3.25 even up to $3.75, with of course little tonnage moving. There continues to be an increasing contract activity, with prices fixed similar to those quoted above. While some contracts are dated to begin Apr. 1, many do not call for shipments until several months later, even up to June 1. At this time the railroads are not actively in the market for fuel, but there are indications that they will be ready to close agreements by Apr. 1.

BALTIMORE

Prices quoted at mines more even than at tide, where there is an unusually wide range for bituminous coals. New York strike and embargo cuts loose some cheap fuels in this section, and the market is strictly one for buyers and not sellers. Hard coal dealers here to take up retail price question during week.

Bituminous—A tremendous effort is being made by producing concerns and distributors to hold up the market, but the success has been rather indifferent at times. Some high-grade coals, it is true, are being held firm at the old Government maximums or better, but other high-grade coals are selling much off that figure. Some operators have agreed to stand by others in their regions to protect fuels, and then openly admit that some sales have been made below the quotations they give when approached. At tide the sales of coal caught here have gone over one of the widest ranges in years, practically the same grade of coal selling to the trade on a single day at prices ranging from a little over $2 on up to $2.75.

The strike in New York harbor has had a distinct effect here. Much coal has been caught away from New York by the embargoes, and has either been shunted into this and other eastern territory or is standing on sidings at the mines or along the railway lines to the coast. This coal in some cases is now offering cheap and hurting what would otherwise be a firmer market.

Another disturbance to the local situation was the release here during the week to the bunker trade for foreign vessels of some 180 cars of coal which the Navy had standing at the Canton pier of the Pennsylvania R.R. since December. Vessels were ordered to take this coal to the exclusion of private shippers. This coal is being fast cleared up, but the Navy has another lot at Curtis Bay and a big storage pile at a water-front ordnance depot; and there is a fear in the coal trade that this, too, will be released.

Anthracite—The hard-coal dealers have taken no steps as yet to fix an April selling price to the public here. The various wholesale schedules are awaited first. The members of the board of the Baltimore Coal Exchange will take up the subject some time this week and will then call a meeting of coal dealers to arrange a schedule of sales. It is probable that the margin of profit as allowed during the war by the Fuel Administration will be followed. This may give a slight cut in the spring and early summer from the existing retail schedule, and possibly a slight advance when the full over-summer 50c. raise in wholesale prices becomes reflected in the retail selling here.

Lake Markets

PITTSBURGH

Production remains very light. Market slightly more ragged. Steel industry's coal consumption may not decrease further.

The coal market is as dull as ever, and is somewhat more ragged. Production remains at 25 to 30 per cent. of capacity, not having improved appreciably, while it still seems to be a shade in excess of actual requirements, so that odd lots of coal are frequently forced on the market at cut prices, below the accepted levels of $2.35 for mine-run and $2.60 for ¾-in. gas. In the case of demurrage coal sales are sometimes made at under $2.

Coal consumers are showing the utmost conservatism and evidently will consume practically the last ton of coal in stock piles before making extensive purchases, their theory being that while demand for coal may become much more active it is quite improbable that any demand can develop that would send prices above the present asking levels.

Very little contracting has been done for the twelvemonth and operators are no longer making any effort to close contracts. They realize that the situation will have to work itself out and that the maintenance of prices depends upon regulation of production to requirements.

Coal consumption by the steel industry has decreased further, but the decline in steel mill operations will probably be arrested by the slight price reductions that were made last week under the auspices of the Industrial Board of the Department of Commerce. While these reductions were less than had been expected, they will probably inject a confident feeling in the steel market for a month or two at least.

Apart from occasional sales of odd lots forced on the market, the market is quotable at $2.25@2.35 for steam mine-run, with 1½-in. domestic at but little more, ¾-in. gas coal running $2.50@2.70 according to grade, all per net ton at mine, Pittsburgh district.

BUFFALO

Trade still slow. Light contracting. All mines going on short time. No promise of a stir. Loading anthracite into lake vessels.

Bituminous—The demand continues light. If there is any increase most of the trade have not observed it. The warm weather has had much to do with the small consumption of coal. Nobody recalls such an open winter. Last year it was May before the lakes were open, this year they have not frozen at all. Jobbers are not receiving many contract inquiries, for consumers still expect a decline in prices.

The price of high-grade bituminous is still at former Government figures, though some low grades are selling at a reduction, with certain members of the trade trying to maintain that these cut prices are the prevailing ones. Quotations: $4.65 for thin-vein Allegheny Valley; $4.45 for Pittsburgh and No. 8 lump; $4.20 for mine-run and slack; $5.65 for smithing and smokeless; $5.60 to $6.10 for cannel; all per net ton, f.o.b. Buffalo.

Anthracite—The situation remains as before. This winter is gone and only the smallest amount of buying will take place till the consumer begins to stock up for next winter. Some demand will arise before the May advance, but nobody knows whether it will be of much account. Shipping agents are overrun with coal that they have had to put into lake vessels in order to escape paying demurrage on it. The outlook is not for a very active season. The Canadian anthracite trade is as quiet as the Buffalo trade, with dealers often carrying wood, coke or bituminous coal which they bought against a possible giving out of anthracite, and which they cannot sell now at any price.

CLEVELAND

Decided improvement is noted in bituminous shipments to northern Ohio, the bulk of the increase going to Lake Erie ports for loading in lake carriers. Steam-coal users are buying more freely. Prospects are that the lake season will open slowly, but wind up just the opposite.

Bituminous—Considerably more snap is being evidenced in the bituminous markets. This is believed to be due principally to the formal presentation of wage and other demands by No. 8 district mine workers, and the consequent fear of a tie-up when peace is actually declared and negotiations be-

tween operators and mine workers get under way. Stock piles in many cases are showing bottom now, while quite a volume of business, for some time repressed by high prices, is believed to be on the verge of coming out. The outlook altogether is the best in some weeks. The sight of bituminous destined for lower lake car dumpers is most cheering, too.

The subject of price has come in for considerable consideration lately and many informal discussions are said to have been had by No. 8 district operators. The sentiment is said to be almost unanimous that present prices are too high. Whether a reduction would stimulate business is the question. Some operators have favored reductions ranging from 45 to 25c. off the $2.60, f.o.b. mine price fixed by the United States Fuel Administration for prepared sizes. There seems to be no question but that when the price of lake coal for the 1919 season is fixed it will be under the 1918 figure. No. 8 district operators are anxious to have the matter of price adjusted as soon as possible in order to get the lake season away swiftly.

Lake Trade—Though quite a number of early cargoes are being floated, the 1919 season on the Great Lakes probably will not be in full swing until the end of the first week of April. The season is expected to open a great deal slower than normal, due to stocks carried over by upper lake docks and the uncertainty of prices. No. 8 operators fear that while the season will open slowly it will wind up with a rush. The No. 8 district, which sent forward 5,249,728 tons to the upper lakes last season, undoubtedly will far exceed that figure this season. Estimates of total bituminous lake shipments in the 1919 season all range around 22,000,000 to 23,000,000 tons, compared with 28,000,000 tons in the 1918 season.

Coal prices, per net ton delivered, are as follows:

Anthracite	
Egg	$10.80@10.95
Chestnut	11.00@11.10
Pocahontas	
Lump	7.50
Mine-run	7.20
Domestic Bituminous	
West Virginia splint	7.05@7.15
No. 8 Pittsburgh	6.15@6.35
Massillon lump	6.95@7.10
Steam Coal	
No. 6 slack	4.45@4.55
No. 8 slack	4.90@4.95
Youghiogheny	4.95@5.05
No. 6 mine-run	4.35@4.55
No. 8 mine-run	4.90
No. 8 ¾ in.	5.45@5.55

DETROIT

Small orders from retailers for domestic lump are said to form a large part of the present business of jobbers, with the steam trade inactive.

Bituminous — Unsatisfactory conditions are encountered by jobbers who attempt to sell bituminous coal in the Detroit market. The volume of business is described as small. A considerable proportion of it is said to be made up of small orders for lump from retail dealers, who desire to supply a household demand without greatly increasing stocks on hand, which in most instances consist of mixed sizes and much coal of inferior quality.

Efforts to interest consumers of steam coal in offerings of high-grade stock formerly popular in the Detroit market are disappointingly unsuccessful, due to the unusually large reserves in storage yards of most of the buyers. Because of the quantity of coal at hand, few of the large steam-coal users manifest any inclination to consider contracts at this time. Their backwardness in this respect, jobbers say, is also the result in part of an idea that coal can be had cheaper by holding off.

Slack is proving especially hard to move. While in comparison with previous years the quantity of slack reaching Detroit is small, there is apparently no present demand. Prices are said to have been reduced on some offerings as much as $1 below the Fuel Administration level. Mine-run also is not easy to place, and low prices have been quoted by some dealers. On domestic lump and egg sizes, prices are being kept fairly steady around the mark set by the Fuel Administration, jobbers say.

That certain producers are doing more to impair stability of prices than any other factor in the market is asserted by some of the jobbers, who say they have learned of attempts to sell coal at very low prices to consumers, who owing to their heavy reserves indicated no interest in the propositions they received.

Anthracite—Inquiry for anthracite from household consumers was more active during the recent period of cold weather. Retail dealers in most instances were able to supply all requirements for any size of anthracite. There was a broader inquiry also for coke, the supply of which seems fully sufficient for the needs of the market. Dealers say a considerable quantity of domestic coke is now arriving in Detroit.

COLUMBUS

A slight increase in the demand for steam grades has developed in the Ohio coal trade recently. Domestic business is slow and little tonnage is moving. Prices are uncertain, but the larger companies are maintaining Government quotations generally.

In almost every locality there is a little current business to report, but the tonnage moving is not large. Purchasing agents are more disposed than ever before to discuss the question of fuel, but they are still holding off when it comes to signing contracts for any large steam tonnage. A large number of contracts expire around Apr. 1, and there is much uncertainty in the future. It is reported that a large contract has been closed at a reduction of 10c. under the Government figures. There is sufficient spot coal moving to take care of current demands. Reserve stocks are still large and in some instances are sufficient to last from four to six months.

The domestic trade is quiet in the extreme. Retailers are not buying, as their stocks are large. There is some demand for the so-called fancy grades such as Pocahontas and West Virginia splints, but this is not sufficient to cause much activity in the trade. Householders are not stocking up for the future and reports show that a considerable tonnage will be carried over until next season. Dealers in this territory do not expect much trade until later in the summer. Country dealers are preparing for a number of orders during the summer to take care of the threshing demand. On the whole, the retail trade is slow, because of the unusually warm weather that has prevailed and the large stocks. Prices are pretty generally maintained, although some cutting is reported.

CINCINNATI

Contract business is attracting attention, but is not progressing rapidly on account of situation in the market. Current demand remains moderate.

With an improved condition in the general situation, brought about by the advance of the season and the changed attitude of consumers with reference to the fuel supply, attention has naturally been centered more on the status of contracts for the coming year; and a peculiar situation has been noted. While large users of fuel are willing to contract, provided they can secure low prices commensurate with the comparative dullness of the market, producers are not willing or anxious to contract at such prices, as they are by no means sure they can make a satisfactory profit under the uncertain conditions existing in the industry.

Operators openly declare that they prefer to let contracts slide rather than bind themselves to furnish coal for an entire year at rates which might in all probability fail to yield a living margin. This attitude seems to be growing stronger as the season advances, and the impossibility of keeping the coal trade on a starvation basis becomes more apparent. It is not at all unlikely, therefore, that before long the logic of the situation will force a decidedly higher level of prices for contracts to be entered into, and that this in its turn will operate to strengthen the spot market, thus helping things all around. A more optimistic feeling regarding the amount of coal carried over is also in evidence, as it seems that this is not going to interfere materially with purchases for next winter on the part of domestic consumers.

LOUISVILLE

Conditions showing slight improvement and general trade taking on more optimistic air. Steam demand improving somewhat, and numerous inquiries being received on contract prices.

Operators are generally more optimistic concerning the market during the spring and summer months. During the past month inquiries on quotations for annual contracts have been coming in well, and a fair volume of business has been landed. However, operators as a rule are not sure of the labor situation, and are going slow when it comes to quoting prices below the former Fuel Administration maximum price, on contracts. A few operators are cutting prices for immediate business, but standing pat on futures.

The coal trade generally is strongly in favor of the news items appearing in daily papers relative to summer stocking for domestic consumers. It is believed that the remnants of the Fuel Administration can do some excellent work via the publicity route in showing the consumer that prices are firm, stocks being depleted, and that it will be a wise policy to stock during the spring and summer months, especially if the consumer desires the better grades.

Prices are fairly firm, but there is some price cutting being done. One large retailer reported that he had been offered the best eastern Kentucky run-of-mine at $2 per ton, which is between 20 and 50c. under the market. At this price he purchased some stock, as he figured he could handle it through his own screening plant, screen 65 per cent. lump and come out well at the price.

The market this week per short ton is quoted as follows:

	Eastern Kentucky	Western Kentucky
Block and egg	$2.85@$3.00	$2.60
Run-of-mine	2.20@2.40	2.35
Nut and slack	1.90@2.10	2.05

BIRMINGHAM

Consumers of steam coal reluctant to enter market. Domestic grades continue to enjoy a fair demand, though the supply is being curtailed by the dullness in steam trade. Production showing a gradual decline.

The Birmingham coal market is very quiet and steam users as a whole are not taking much coal in the spot market, though there is a good sprinkling of small orders, and inquiries are now being received from contract consumers. It is expected that some improvement will be seen in the trade within the next two weeks. The largest contracts closed so far were for 10,000 and 12,000 tons of railroad fuel at the last named Government figures. Some export business is being gradually developed, 1000 tons of coal from this field being shipped to Cuba through the port of New Orleans the past week, and orders are in hand for several thousand tons more. Bottoms are hard to obtain for export business, shipowners stipulating the tonnage they will handle, which in many cases is in excess of tonnage to be moved. Prices are being rigidly maintained on the basis of last Government schedule, and are as follows per net ton mines:

	Mine-Run	Prepared	Slack and Screenings
Big Seam	$2.45	$2.70	$2.40
Black Creek and Cahaba	3.45	3.75	3.05
Corona, Jagger and Pratt	2.85	3.05	2.45

While there is little demand for domestic coal from consumers on account of mild weather conditions, the wholesale trade is fairly good and the output of the mines is readily marketed. Domestic sizes are not any too plentiful, as the output of lump and nut from steam producers is far below normal. Contract buying is expected to begin between now and Apr. 1. Domestic quotations are as follows:

	Lump and Nut
Black Creek and Cahaba	$3.85
Corona	3.65
Carbon Hill	3.15
Climax and Montevallo	5.00

Commercial mines in this field are running from two to five days per week. Furnace companies have curtailed production considerably, the Woodward Iron Co. having closed down practically all its mines, its furnaces being banked, while other large ironmakers have closed down some of their large operations pending a revival in the pig iron trade.

Coke

CONNELLSVILLE

Market prices fairly well maintained. Production relatively low. Reduction in pig iron pleases coke operators.

The reduction of $4.25 in pig iron prices arranged last week between the Industrial Board of the Department of Commerce and representatives of the merchant pig iron producers, proved to be quite a satisfactory piece of intelligence to the coke producers. The coke producers wanted pig iron to be reduced so that demand for pig iron might be stimulated, whereby more coke would be consumed, while at the some time

they did not want to see pig iron reduced so much that claims would be made for further reductions in coke prices. The pig iron reduction went about as far as it could without furnishing grounds for bringing up the subject of coke prices, except in the case of contracts that had been written at "last Government price," such contracts having been adjusted down only as far as $5, except in one or two instances, in which no adjustment at all had been made. With coke at $4, or one-third less than the Government limit, it is in line with basic pig iron at $25.75, valley, the new price, against the last Government price of $33.

The furnace coke market is a shade easier than a week ago, but is not quotably lower. Recognized standard brands of furnace coke are still held at $4, for both prompt and nearby shipment, and this price has been paid freely by furnacemen who wanted fair-sized lots of standard grade. Sometimes the price has been shaded fractionally, while coke of only fair reputation has sold in a few instances at $3.75. In the case of foundry there is a wide variety of fairly good brands to select from at $4.50, while two or three old line operators still adhere to $6. The market is thus quotable at $4 for furnace and $4.50@6 for foundry, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Mar. 15 at 202,308 tons, a decrease of 20,618 tons. While the production was lower than in three weeks preceding, it was about the same as production in the week ended Feb. 15.

Buffalo—The demand for coke is light and the outlook for the season is still not well defined. While it is quite certain that about the same amount of iron ore will be moved as in recent seasons, the ore men are waiting for general developments. No lake charters have been reported yet. The lake fleet is not fitting out as it would if good business was expected early, and brisk operations are expected only late in the season. The coke market is dependent on the ore movement and must wait for it. Quotations are $7.60 for 72-hour Connellsville foundry and $6.60 for 48-hour furnace. Off-grade is unsteady and hardly quotable.

Middle Western

GENERAL REVIEW

Market continues dull, though inquiries are coming in. Expect that labor troubles will interfere with industry in near future.

The coal market in the Middle West continues to be uniformly dull, and with a general lack of interest expressed on the part of the consuming public. The weather may have something to do with this, as the Middle West territory has been enjoying some nice spring weather for the last week. Inquiries are coming in a little faster than heretofore, but this is only natural, as we are now in the midst of the contract season.

To date the buying public have not shown a very keen interest in placing its coal requirements under contract, and the coal men are a little worried over the attitude the public is taking, as each operator has a clientele of special friends that he does business with year after year that he wishes to protect. The difficulty of the situation is that the average coal men confidently expect some labor troubles a little later on in the season. Whether it will affect his field or fields further east, he is not prepared to say, but he does know that should any important coal-producing district be tied up with a strike, the result would be that prices of coal in the non-affected fields would promptly advance.

The industry as a whole is not as yet on a stable footing. However, we understand that the new prices on steel products will soon be published as a direct outcome of the steel men's conference recently held in Washington. If something like this could be done with the lumber and coal business—especially coal—it would be a great benefit to the trade.

There has been no more price cutting on this market than usual, and in this price-cutting game the small operators appear to be the chief offenders. We think men, who from the standpoint of production are perhaps in the minority, are doing the industry as a whole a considerable amount of harm, and it is to be hoped that some means will be worked out by the National Coal Association to curtail their activities in this respect.

Reports show that manufacturing conditions, taken as a unit, are improving. Factories are working now that were idle a few weeks ago. The country is getting a little more confidence, but in view of the fact that there is still so much coal in storage, the effect of this confidence has not as yet been felt in the coal industry.

CHICAGO

Steam trade dull, while domestic demand is picking up.

There is absolutely no change in the steam market in this city since last week. Everything continues along dull lines, with no big sales reported. The domestic situation is a little better, as the dealers are now doing some business. It seems that the householders have just about cleaned up their coal bins, and as their furnaces will have to be kept going for at least another six weeks, the dealers are planning on a fair business from now on. There has been some domestic buying, most of it Franklin County or Eastern coal.

Prices per ton are as follows:

ILLINOIS

Southern Illinois Franklin, Saline and Williamson Counties, etc.	F.o.b. Mines	Rate to Chicago
Prepared sizes	$2.55@$2.75	$1.55
Mine-run	2.35@ 2.50	1.55
Screenings	1.85@ 2.20	1.55
Central Illinois Springfield District		
Prepared sizes	$2.55@$2.75	1.32
Mine-run	2.35	1.32
Screenings	2.05	1.32
Northern Illinois		
Prepared sizes	$3.25	1.24
Mine-run	3.00	1.24
Screenings	2.75	1.24

INDIANA

Clinton 4th Vein District		
Prepared sizes	$2.65@$2.75	1.27
Mine-run	2.35@ 2.45	1.27
Screenings	2.05@ 2.25	1.27
Knox County Field		
Prepared sizes	$2.65@$2.75	1.37
Mine-run	2.35@ 2.45	1.37
Screenings	2.05@ 2.25	1.37

MILWAUKEE

The fact that there are no dealers buying keeps soft coal from sagging, despite cutting at the mines. Very little doing.

The coal market at Milwaukee has developed no new features since last week's report. Stocks continue to move off slowly. There is much more soft coal on the docks and in interior retail yards than will be called for by the end of the coal year. But for this fact prices of western grades would have been on the toboggan ere this, as Illinois operators are shading prices in an endeavor to stimulate business. The first dealer who buys at the new rates will let down the bars. Prices of all grades of coal and of coke are firmly held, with everybody in the trade guessing how long it can be maintained. The supply of anthracite is being reinforced by rail, but dealers are looking for an advance in the price of hard coal. The weather continues mild for the season and everything points to an early spring.

Following are the coal prices at Milwaukee, per short ton, effective Mar. 1. The prices given include delivery. At the yards the prices are 50c. per ton less:

Domestic	
Anthracite—	Short Ton
Egg	$12.20
Stove	12.40
Nut	12.50
Pea	11.00
Buckwheat	10.60
Bituminous—	
Pocahontas mine-run	$8.15
Hocking, screened	7.90
Youghiogheny, screened	7.90
Pittsburgh, No. 8, screened	7.90
West Virginia, screened	8.40
Splint, screened	8.40
Kentucky, screened	8.40
Illinois, screened	7.25
Coke—	
Solvay, large sizes	$11.50
Solvay, small sizes	10.25
Smithing	8.40
Steam—	
Youghiogheny, Hocking and Pittsburgh	
No. 8, screened	$7.18
No. 8, pile run	6.93
No. 8 screenings	6.68
West Virginia, Kentucky and splint	
Screened	7.68
Pile run	7.43
Screenings	7.18
Illinois and Indiana, screened	6.50
Pile run	6.25
Screenings	6.00
Smithing	7.68

ST. LOUIS

Market continues inactive, with promise of better screening conditions. Situation is extremely trying, with no demand at all for any kind or size of coal.

There has been a slight increase in the demand for steam coal from the Standard field in the past few days. At least, it has been noticeable that screenings moved from some mines that have been unable to work on account of a surplus of screenings. There is, however, a noticeable falling off in the demand for lump in the Standard district, for both steam and domestic. This would indicate that the lump coal will be easier and the screening and steam market will become stronger.

Locally there is no demand for either steam or domestic Standard coal. A few plants here and there are getting a few cars in, but it has not affected the market as yet. Some mines are working one and two days a week; others are not working at all. The railroad tonnage the last week increased somewhat. It has been reported that the railroads have been instructed from Washington to let their storage coal remain on the ground and give the miners as much work as possible on new coal.

In the Mt. Olive field similar conditions exist, although most of this coal is moving north, with a little railroad tonnage to help. This market is inclined to be fairly steady and holding to the Government price. Mines in this district are working about two days a week.

In the Carterville field of Williamson and Franklin County, as well as in the Perry County field, there continues to be an over-production. Steam sizes, such as screenings, have kept many mines shut down on account of their inability to move. At other mines the domestic sizes are piling up. The railroad tonnage from this field is not what was expected, but is moving out on contract principally. These contracts are not profitable. The Missouri Pacific contract at the present time calls for $2.07½ for mine-run coal.

The operators in the Franklin County field, however, are turning down all cheap prices, and the prices in the Franklin County field are holding up stiffly, while Williamson County is inclined to be a little bit weak; so is Perry County.

Business conditions in general are not good throughout the Mississippi Valley at this time. That is one reason why the steam sizes are heavy. There is no immediate chance of improvement.

The prevailing prices are per net ton f.o.b. mines:

	Mt. Olive and Staunton	Standard
Franklin County		
Prepared sizes, lump, egg, Nos. 1 and 2 nut	$2.75	
Williamson County		
Prepared sizes, lump, egg, nut	$2.55	$2.55	$1.90@2.25
Mine-run	2.20	2.20	1.60@1.70
Screenings	2.05	2.05	.95@1.10
3-in. lump	....	2.30	....
2-in. lump	....	....	1.75@1.90

Williamson-Franklin rate to St. Louis is $1.10; other rates 92½c.

HAMPTON ROADS

The following are the prices of anthracite and bituminous coal at retail per ton of 2000 lb. delivered on the different grades of coal enumerated. These prices hold good until Apr. 1, 1919:

Pennsylvania anthracite	$11.70
Pennsylvania anthracite, half ton	6.00
Pocahontas egg	8.90
Pocahontas, run-of-mine	7.90
Pocahontas lump	8.90
Pocahontas nut	8.90
Splint	8.50

Pocahontas and New River run of mine $4.85 per net ton on tracks in carloads; for foreign shipment, $5.40 per gross ton; for coastwise shipment, $5.10 per gross ton; for bunker purposes, $5.40 per gross ton, plus expenses of delivery. A war tax on railroad freight charges in addition to all the foregoing prices.

Suppliers are offering Pocahontas and New River run of mine for local industries at $4.85 per net ton, plus war tax on railroad freight, delivered on track or over piers for the year commencing Apr. 1, 1919.

COAL AGE

Volume 15 New York, April 3, 1919 Number 14

Getting Rid of Unrest

By Floyd W. Parsons

NOW we learn that the total cost of the war to the United States from April 6, 1917, to June 30, 1919, will be $30,205,000,000. This is three-fourths the size of England's war expenditure, one-fourth larger than the debt of France, twice that of Italy and fifteen times the war debt of Canada. Compared with Germany, the United States expended two-thirds as much as did the Teutons, while balanced against the cost of our Civil War the conflict just closed, although shorter, cost five times more.

From whatever angle we view the past four years there is no escaping the conviction that the world has been struck a harder blow than ever before in history. Exclusive of losses of lives and property, the cost of the war in money alone amounts to $200,000,000,000. Of all the countries that have suffered, the United States undoubtedly will be able to meet and pay off its obligations far in advance of other nations. However, while we have been running up our huge debt, which necessarily modifies the normal course of our daily lives, the mental enlightenment of the world has gone marching on, and it will require a great effort for the physical and material elements in life to catch up with the mental and spiritual side of humanity.

It makes little difference to a workman whether the head of his government is a democrat if the head of his company is an autocrat. National justice is not worth much if local injustice is permitted to flourish. The degree of contentment and happiness that surrounds an employee is determined by the character of his employer, not by some man with a new idea in the capitol at Washington. If labor unrest is attacked at the root, the plant will never grow and ripen above ground.

The way to kill anarchy and Bolshevism is to eliminate human unhappiness. We are experiencing the action of a leveling process. The so-called common people are demanding and must receive an increasing share of the good things of life. If these changes are to proceed along sound economic lines — if we are to have evolution instead of revolution — the people who have most must more speedily recognize the rights of the people who have least. There must be the recognition of the dignity of labor in terms other than money. Wages are not a universal cure-all.

Of all the important questions that bear on the lives of workmen and that influence their attitude toward existing conditions no problem is more vital than that of health. We have an enormous war debt to settle, and it can only be paid by exercising constant energy and high efficiency. Industry and health go hand in hand, while disease and incapacity travel together. We aim to eliminate poverty, and sickness is one of the chief causes of human want. In a community where ill-health prevails, the soil is fertile for the sowers of discord.

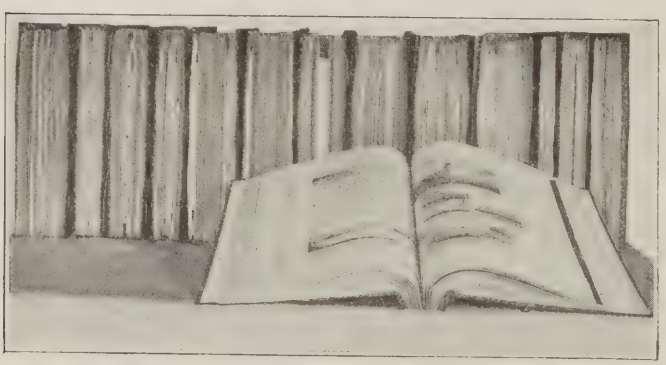
One of our great corporations long ago accepted the idea that health and safety are prime requisites in the promotion of industrial peace, and in twelve years this concern has saved 23,000 men from accident. It has also profited in compensation insurance alone to the extent of more than six million dollars. The company's employees are supplied with hospitals, wash and locker rooms, restaurants, playgrounds, good fellowship clubs, evening schools and attractive houses with splendid sanitary appointments. There are also visiting nurses, housekeeping centers for the training of the workmen's wives, gardens to supply fresh vegetables and community cellars where any oversupply of vegetables raised by the employees can be stored during the winter months.

In and near hundreds of mining camps there are foul swamps that cultivate swarms of disease-carrying mosquitoes, while only a small expenditure will rectify the trouble. Other mining towns harbor cesspools, earth closets and open manure pits, breeding millions of houseflies in close proximity to unscreened kitchens, and yet there are people who lay the epidemics of malaria and typhoid to things supernatural.

Any company official who is looking for a way to justify receiving the salary he gets need seek no further than the problem of health. Here is a work that can be made to pay dividends in the kind of self-satisfaction that comes from real service as well as in dollars earned.

IDEAS AND SUGGESTIONS

Keep Useful Articles for Reference



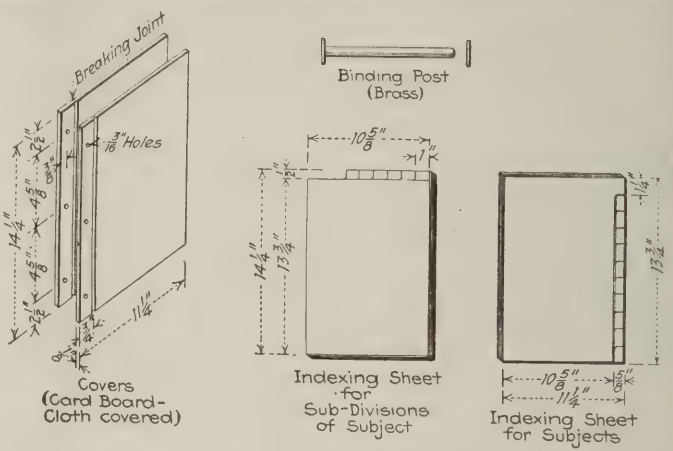
By A. H. Myers
Chief Inspector, Marine Department, Wellman-Seaver-Morgan Co., Akron, Ohio

It is well said that "He who reads and throws away may live to rue that very day." The adage forces itself on the attention when one is vainly searching for an article which impressed one at the time of reading it as likely to be of assistance. I purpose to describe a filing system that I have used successfully for many years.

It has been my practice to save articles appearing in many different periodicals and also bulletins of various engineering projects, if not too bulky, binding them between a pair of stiff cardboard covers, with brass binding posts, using separating or indexing sheets of paper between them. The sketches show the details of the method adopted.

The binding posts of the 4-in. size, the largest size on the market, can be purchased from an office outfitter for about 3c. each. Any bookbinding establishment should be willing to make the covers for about 80c. a pair. The paper to use as separation sheets can be purchased at the same establishment, being later cut as required. Covers of the size shown will serve for the filing of any articles which have been taken from any of the American publications now being issued.

The most convenient part of the filing system is the separating or indexing sheets which are bound in with the articles, being arranged according to the alphabetical order of the subjects thus indexed. There are subject-headings at both the right-hand side and the top of the separation sheets. The right-hand notations indicate the subject proper, while the top notations



HANDY INDEX FILES OF EXCERPTED ARTICLES

indicate the subdivisions of the subject. For example, suppose the subject of boilers is to be referred to: the subdivisions that appear as top notations are construction, operation, land types, testing, marine types, etc., the subdivisions being added as the articles are procured.

When removing articles from periodicals do not cut out the article with a knife, but pull out the binding wires of the magazine with a pair of pliers. This is the better plan, for when an article is cut out of a magazine there is seldom a sufficient margin left for filing.

It can readily be seen that a system of this kind can be made comprehensive and yet simple, for all the articles saved on any given subject are in one place and not scattered all over the library, as would be the case if they were bound up with articles which the reader does not want but which appeared in the same issues with the desired articles. The photograph shows

DETAILS OF FILE FOR MAGAZINE ARTICLES

to what modest proportions my article file has attained in 10 years.

Because of the labor involved in opening up the volumes for filing, I do not usually file the articles as they are received, but lay them away until a sufficient number have accumulated to make their insertion advisable, memory being relied upon in the meanwhile or entries being made in a card index.

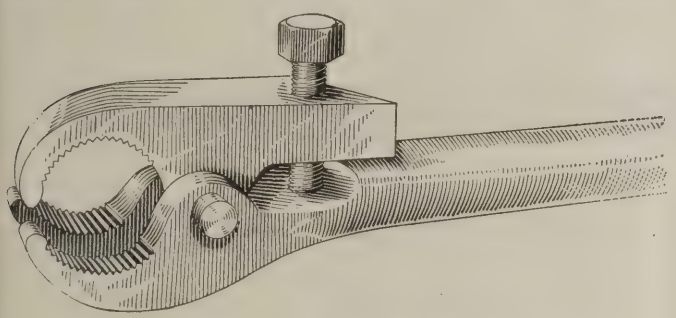
All persons who file data should maintain a card index in which should be listed all books, papers, etc., in the library. The card index, although not absolutely necessary for this type of article file, is nevertheless a good standby.

And now a word as to filing of catalogs, pamphlets, books, etc.; I use a system of letters to designate the heights of the books as they stand in the book case and numbers to designate any given book. Thus all books over 10-in. high are designated by the letter A, all between 9 in. and 10 in. in height by the letter B, all between 9 in. and 10 in. in height by the letter C, all under a height of 8 in. by the letter D. A standard sectional book case with a drawer for the card index is used for filing.—*Engineering News-Record.*

Extending a Long Straight Line

When a long tangent is being laid out on a railroad survey, or when any large number of stakes for any reason have to be set in a line, it pays the transitman to drive a special (or datum) stake in an easily visible location with an upstanding tack, so that he can test the alignment rapidly and without focusing or plunging the telescope and without the assistance of a flagman. A movement of the transit is always apt to occur and to

cause a swerve in the line. This is especially true if the instrument is set on the ground, which should rarely be done, for it is almost impossible to guarantee that it will remain just where it stood when first placed unless pedestal stakes are firmly driven and the instrument erected on these.



It quite frequently happens that the plummet, after the transit has stood awhile, fails to plumb to the instrument point. In this event the tack on the datum stake will not register the exact line, but it will prevent the error from being as great as it would have been if the tack had not been used; especially if the datum stake is set at a point quite remote from the transit. Most transitmen when running a tangent line for locating houses, lots, sewers or grades waste more time bringing the instrument back to line and position than they would waste if they, from the first, provided the instrument with a pedestal of undoubted permanence and located a suitable datum stake for readily testing the accuracy of their work.

Sure Grip Pipe or Stud Wrench

By Charles H. Willey

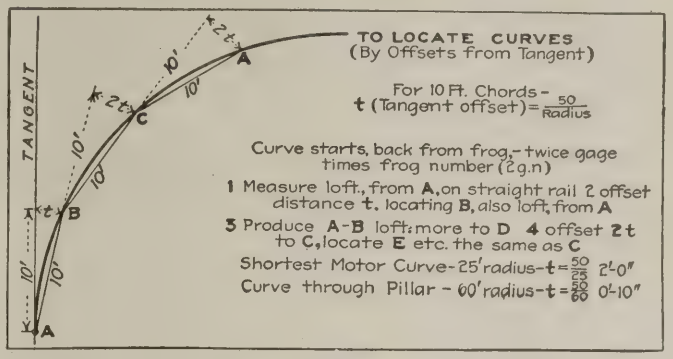
Concord, N. H.

A sure grip wrench may be made in a size to suit one's needs in a form similar to that shown. It can be used for gripping any round stock, pipe, studs and similar material. The device was invented to answer

WRENCH FOR ROUND STOCK

the need of a positive grip wrench for removing stubborn pipe and studs. The pin is slipped out when putting the wrench on or taking it off the work. By screwing down the screw the jaws of the wrench exert an enormous grip on the pipe or stud.

To Locate a Curve with a Tape



By Harry Goodnow

Du Quoin, Ill.

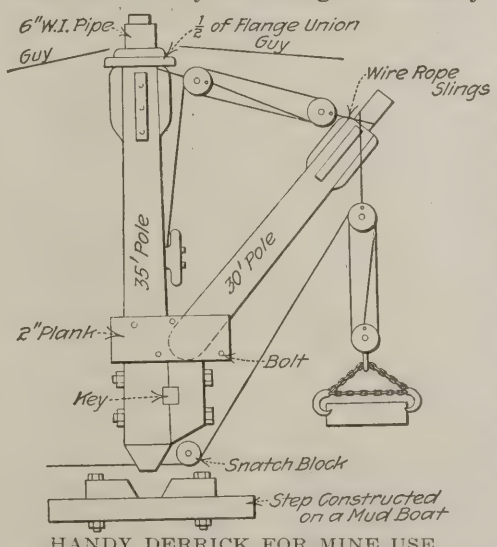
The other day I was drawn into a discussion between the "Big Boss" and the "Little Boss." A switch had been laid for a turn from a main entry into a panel entry. The Big Boss said there was not room for starting a turn over which an 8-ton motor could pass successfully, and that the switch would have to be torn up and relaid, starting further back in the entry. The Little Boss was sure the curve would go in all right.

We finally agreed, after measuring another short curve in the mine, that a 25-ft. radius curve was the shortest over which the motor could operate. As the engineer I was asked to stake out such a curve and see whether or not it would lie within the confines of the entry in question. It would—with few inches to spare—but anyone except a first-class tracklayer would have failed in his task without stakes, as the curve had to be absolutely uniform.

It occurred to me then that such questions often come up and that there is seldom an engineer on hand to settle them. Accordingly, the accompanying data

CURVE DATA SHEET

were drawn up on tracing cloth and blueprints made for several of the bosses.



It is my belief that the blueprint is self-explanatory. However, I would advise a little teamwork between the boss and the local engineer so that no mistakes will be made through lack of understanding on the part of a boss not used to such work.

Improvised Derrick Without Usual Irons

By Samuel P. Baird

Columbus, Ohio

The accompanying figure illustrates an improvised boom derrick, built without the derrick irons which would ordinarily be thought necessary. The principal features are the step-bearing for the mast, the step for the boom and the means for allowing the mast to rotate at the top. The rope used was 1-in. manila, the boom hoist was a pair of double blocks, and the main hoist was a combination of a double and a triple block. The main power was a steadily moving team. The loads lifted were stone weighing about a ton, and they were raised high enough for a truck to back under. A friction drag was provided on the main fall line, so that the load could be lowered gently. With this provision the team could be permitted to return as soon as the load was raised to the desired height. Thus it was ready to be hitched onto the rope for the raising of the next stone as soon as the first was lowered into place.—*Engineering News-Record.*

HANDY DERRICK FOR MINE USE

The Yellowhead Coal District

By S. Mac Vicar
Coalspur, Alberta

SYNOPSIS — *Two coal beds on a steep pitch are worked simultaneously by means of a balanced plane. Each balanceway produces about 75,000 tons of coal and requires nothing but gravity for its operation. The coal produced finds a ready market and the area worked will eventually be one of the most important in western Canada.*

THE Yellowhead coal district is situated in the foothills of the Rocky Mountains, about 180 miles by rail west of Edmonton, Alberta. It is served by a branch of the Grand Trunk Pacific Ry., which leaves the main line at Bickerdike, Alberta, running southwesterly 37 miles to Coalspur Junction, then southeasterly for 20 miles along the same general direction as the strike of the coal beds to the mines of the North American Collieries, at Lovett. Present developments indicate three series of outcrops running through the district, each series containing six large and valuable beds of coal as well as many smaller ones of lesser value.

The beds worked by the operating companies are on the southwesterly slope of an anticlinal fold, the crest of the fold appearing about 1½ miles to the northeast. The measures belong to the Upper Cretaceous period. A section at Coalspur shows the formation to be about 3000 ft. in thickness, consisting of a succession of sandstones, shales and coal beds, with a conglomerate bed near the bottom. The Yellowhead coal beds are in the upper part of the section and the Lovett beds in the lower.

The strike of the coal seams is approximately northwest and southeast, and the dip of the Yellowhead beds at Coalspur is 52 deg. to the southwest. The ridges containing the coal measures are low, except at Coalspur, where they are high and well defined, and are cut at right angles by the Embarass River. The railroad is afforded a natural passageway through by following this stream.

The coal is a hard bituminous of good quality suitable for steam-raising or household use. If mined with care, under proper methods, it will not contain over 10 or 12 per cent. of ash. In Table I are representative figures taken from "Analyses of Canadian Fuels."

The mine-run shipments from this district, in July, 1918, to the Grand Trunk Pacific Ry., showed the analysis given in Table II.

The coal in all cases is non-coking, burning to a gray ash. The Government analyses are a fair representation of what the mined product would be, if the coal was kept clean and free from dirt; also they show that the quality of the fuel over the whole district is very regular. The coal is shipped in the following sizes: Slack, 0 to 1 in.; stove, 1 to 4 in.; lump, 4 in. and up; also mine-run. The slack is used by the cement plants, the Grand Trunk Pacific Ry. at its division points, by power plants adapted to burning slack, and by factories at Prince Rupert.

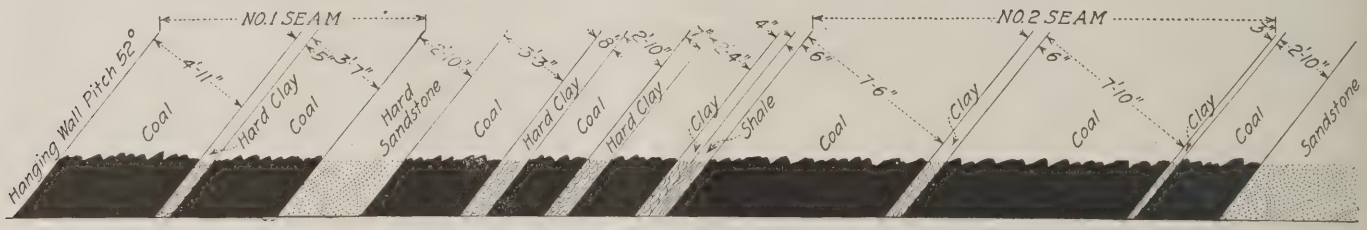


FIG. 1. SECTION OF BEDS BEING DEVELOPED AT COALSPUR MINE OF YELLOWHEAD COAL CO.

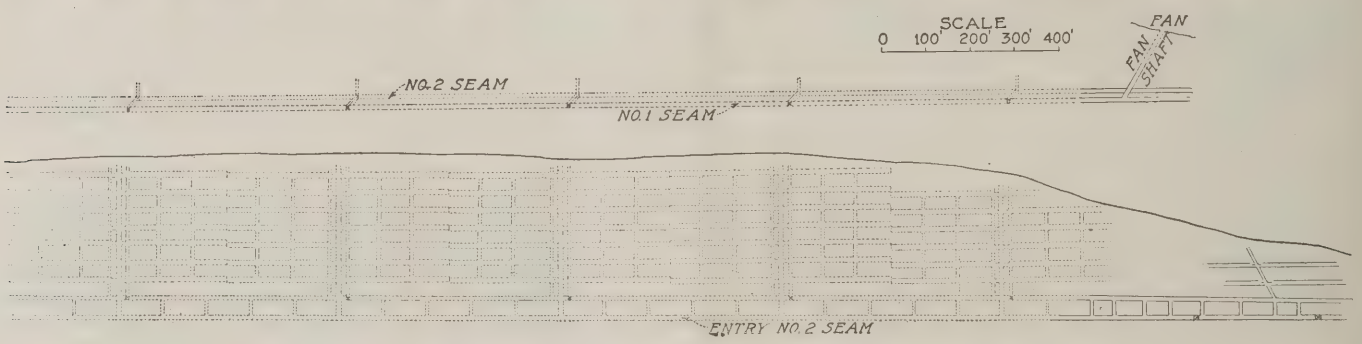

FIG. 2. PLAN OF METHOD ADOPTED TO WORK YELLOWHEAD COAL BEDS

The mine-run is used for stationary boilers, and in the winter season by locomotives. The stove and lump find a ready sale in Saskatchewan and Manitoba, where this fuel is able to hold the market against any coal shipped into these provinces. The coal sells best in lump, and the system of mining adopted must be one that will preserve the lump and deliver it clean and free from impurities.

A section of the beds being developed at the Yellowhead Coal Co.'s new mine at Coalspur is shown in Fig. 1. Fig. 2 is a plan of the method adopted to work these beds. A tunnel driven across the measures, after crossing several seams of varying thicknesses, cuts No. 2 bed 500 ft. from the portal. An entry is driven in this bed with a counter 35 ft. above, and an air-course in No. 1 seam parallel to the counters

in No. 2 seam. The coal from this air-course is dumped into chutes driven across the measures from the entry in No. 2 seam.

When 1100 ft. in, the entry is well under the hill, and one main headway is driven on the full pitch of the seam along the course of the center parting; 12

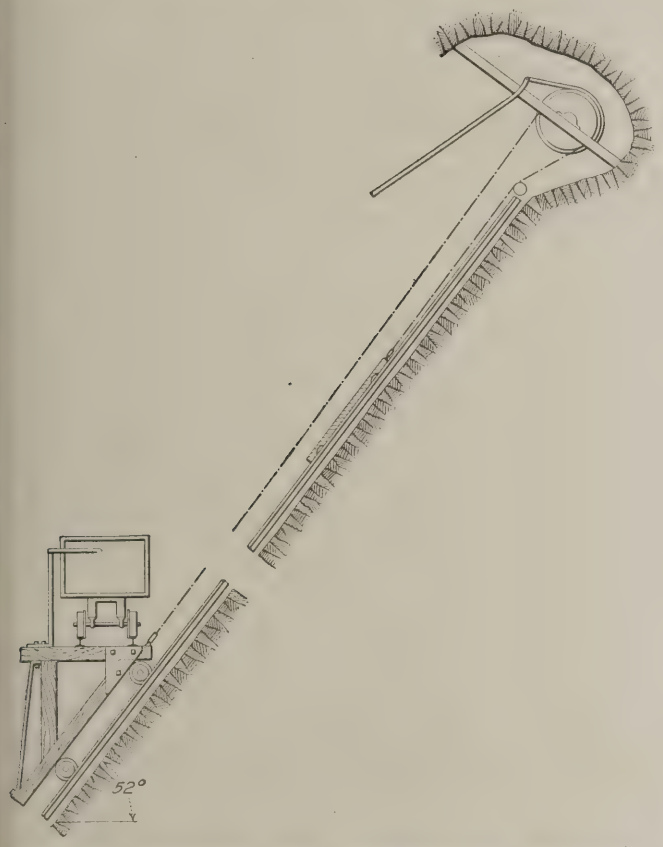

FIG. 3. BALANCED CONVEYING SYSTEM BETWEEN ROOMS AND GANGWAY

ft. on each side of this headway two smaller air-courses are driven in the under part of the seam. As the headway and raises advance roomnecks connecting the raises with the headway are driven at 40-ft. centers.

As soon as one roomneck on each side is completed, the clay minings from the headway, raises and roomnecks above are caught by properly arranged wing boards and stowed in the completed roomnecks. The wing boards are shifted as the raises and headway advance. After the completion of the headway all the refuse from the roomnecks is cleaned out, the headway prepared for balanced haulage, and the raises used for air-courses and traveling ways.

In preparing the headway for the balanced system of conveying the cars between the rooms and the gangway below, the headway is laid with two sets of rails; one of a wide gage to accommodate a triangular shaped cage (Fig. 3 in side view); the other of narrow gage set inside the cage track for a long narrow balance car. A pulley provided with a brake is placed just above the top room. A rope passes around the pulley, one end being attached to the cage, the other to the back balance.

The back balance consist of a weight midway between that of the cage when carrying an empty car and when carrying a loaded car. The top of the cage is a horizontal platform with track placed at right angles to the balance track, and provided with catches. At each roomneck the track is extended close up to the rails fixed on the cage. An indicator is provided for the attendant at the brake, and by an arranged code of signals the cage can be stopped at whatever room is required to be served. At the bottom of the balanced haulage the gangway is widened out to form a pit for the reception of the cage, and a parting is formed for empty and loaded cars. This system enables the coal to be loaded directly at the working face into the mine cars, and the miners may be paid by weight. It insures a minimum of breakage. The timber can be taken up to the working places on the cage, faulty mining can be detected immediately, and machines can be used for cutting the coal.

Four rooms at the top of the balance are developed on each side. These with crosscuts connecting them to No. 1 seam make in all eight rooms on each side of the balance. These will give an output, when machine mined, of 250 to 300 tons per day. After the rooms are driven 250 ft., the pillars are taken out, commencing at the upper one. While the first formed pillars are being drawn, others are being formed by driving rooms further down on the balanceway. A general idea of the method of working may be gained from Fig. 4. The details of the method of drawing the pillars can be gathered from Fig. 5.

The bottom corner of the pillar is taken out, and a face formed across the pillar from room to room, at an angle sufficient to allow the coal to roll to the track and be loaded out. If the pillar is already drawn above,

FIG. 4. METHOD OF WORKING AND (FIG. 5) METHOD OF DRAWING PILLARS

then, when near the gob a shot is put in, breaking the coal and causing the gob to run into the face of the pillar, which is being drawn. When this occurs the miners have a platform of loose gob to work on. Pillar extraction goes on simultaneously in both beds, and on both sides of the balanceway. With careful mining each balanceway will yield over 75,000 tons of coal.

The coal is hard, with no pronounced cleavages. It stands considerable handling without loss and weathers well in the open. It is a long-flamed, free-burning fuel giving off intense heat. The area worked is one of the largest and most valuable in Alberta, and must eventually supply a large portion of the western provinces with fuel for industrial and domestic use.

A One-Year Retrospect of the Coal Industry of Utah

By A. C. Watts
Salt Lake City, Utah

SYNOPSIS — *Many circumstances both within and without the state tended to influence the coal industry of Utah during the past year. On the other hand, some factors that it was anticipated would have pronounced effects have failed to make their influence felt. A steady growth in civic pride throughout the mining communities is noticeable.*

WHILE it is usually considered wise to look forward rather than backward, it is sometimes inspiring to review past events in order the more readily to appreciate what is yet to be accomplished. The following paragraphs deal with conditions that have to a more or less decided extent directly or indirectly influenced coal production in the State of Utah during the past year. No serious attempt has been made to join the subjects treated into anything like homogeneity. They are rather notes more or less at random, covering certain conditions that influenced production and secial conditions in the coal fields.

During the latter part of March, 1918, Mr. Garfield's zoning order was issued and caused considerable speculation regarding its application to Utah and Wyoming mines. Some of the Utah operators interpreted it to mean the elimination of Wyoming coal from markets to the west and northwest of that state. This would naturally result in increased demands for Utah coal. This idea was speedily dispelled by advices from Washington to the effect that the order contemplated no change in the movement of Utah coal and no change in the movement of Washington, Montana and Wyoming coal except to allow these fuels to move further east, thereby increasing their market territory.

Although there were many Austrians and some Germans and Bulgarians working in and around the coal mines of Utah, but little trouble was experienced from them. A few became too outspoken in their allegiance to the Central Powers and in their criticism of this country and were deported, while one or two were interned in the internment camp at Fort Douglas adjoining Salt Lake City. Despite an apparent lack of evil intent among the aliens, the operators took no chances and had their properties well lighted and guarded, and exercised as much care as possible in the employment of men.

One of the main concerns of the operators was the prevention of illegal accumulations of explosives by evilly disposed aliens, if there were such among us. The Government, through the Bureau of Mines, exercised supervision over the sale and distribution of explosives, but the powder regulations of most of the operators have always been strict. To be further on the safe side, the officials of the mines doubled their inspection and in some instances the use of powder in the mines was subject to the inspection of four or five different officials and under-officials.

On Jan. 29, 1918, the Secretary of the Interior ordered withdrawn from entry 40,000 to 50,000 acres of land adjacent to the Price River in Carbon County pending investigation of the feasibility of an irrigation project having as its source of supply one of the main tributaries of the Price River, and embracing a reservoir site in Pleasant Valley, in which is situated the town of Scofield. The significance of this order lies in the fact that if this project is held feasible and adopted, it will mean the building of a new branch line of the Denver & Rio Grande R.R. to the coal mines of the Pleasant Valley district. The building of the reservoir may mean the impossibility of working coal deposits adjoining it. The valley is traversed by great faults which might prove to be efficient water channels. The lands withdrawn from entry embraced many acres of oil-bearing shale.

The success of Liberty Loan, War Savings Stamp and various war work drives in the coal camps has been wonderful. Every one went over the top and the competition between various camps as to which would get over first was keen.

The first Liberty Loan in 1917 was much more difficult to handle. At that time there was not the keen realization of the importance of the loans that was exhibited last year—nor the sense of responsibility. Furthermore there seemed at first to be a belief that the money subscribed was given to the Government, and thereby lost. After a coupon or two had been cashed, the feeling changed and each succeeding loan was easier to handle. A man felt disgraced if he could not take at least one bond.

It was surprising to note some of the subscriptions. One boiler fireman took $1000 of the Fourth Loan. A car dropper who before last year had never earned over $3.15 per day, was found to owr $1700 in bonds and savings stamps. When asked how he did it, he gal-

lantly attributed it all to his wife and said if he had married ten years ago instead of six, he would not now have to work. An old lady who had three sons in the service, one of whom I am proud to say worked for me, came to the office and bought $500 of the Fourth Loan; and when a few hours later she received $90 as the Government allotment from her soldier boys' wages, she went directly back to the office, aded $10 to the $90 and bought a bond for her sons. There were many incidents of this kind, for patriotism runs high in the coal camps.

For war work funds many mines made a monthly deduction of from 25c. to $1 from each man's wages as the contribution of the miners.

The Fourth Loan proved a glorious success and Carbon County was the banner county of the state—its subscriptions averaging $40 for each man, woman and child in the county. For one company, a grand total of $567,419.93 has been subscribed to Liberty Loans, War Savings Stamps, and given for various war funds.

Utah contains many thousands of acres of oil-bearing shales, which Government experts believe capable of furnishing large quantities of oil. The great demand for this fuel for war work has brought attention to the fact that many petroleum fields are barely holding their own in production, and as the demand is increasing all the time some new sources of supply must be discovered. When attention was attracted to oil shales, many people had visions of great wealth and much excitement prevailed. But as yet no real progress has been made toward utilizing the oil shales, and we are still burning coal in our locomotives and furnaces.

Influenza Proved Serious in Utah

The epidemic of influenza which has and is sweeping the country has proved a serious drawback to the coal-mining industry in Utah. Unfortunately, people have not realized the dangerous character of this disease—it has not the terrifying attributes of smallpox, cholera or bubonic plague; there were no flaring yellow or red quarantine signs, nor dreaded pesthouses, and its spread throughout the country has been much more insidious. A community would develop a few cases and then apparently the disease would disappear, but only to break out with greatly aggravated virulence.

Many of the coal camps instituted strict quarantines as soon as the disease appeared and have observed this measure since early in October. It is to be noted that when strict quarantine regulations have been in force, the disease was not very prevalent. It is interesting, however, to recall that in April of last year there was quite an epidemic of colds in some camps, as also in some metal mining towns in the state. The affection was then called LaGrippe, and many miners and coke pullers were off work with it, the coal and coke output being materially reduced thereby. The output at some of the mines has been seriously reduced because of the "flu," and surface improvement operations have in some cases had to be temporarily abandoned.

Some nationalities have strong ideals about preventive measures. For instance, the Greeks eat a great deal of garlic. In one camp there were no cases among these garlic-eating Greeks, but there were among the Italians, who are also very fond of the herb, vegetable or weed, whichever it may be. In other camps there cases of the "flu" among the Greeks—possibly their supply of garlic whichever it may be. In other camps there were cases of the "flu" among the Greeks—possibly their supply of garlic ran out. While the epidemic interfered with output, it is impossible to give accurate data concerning its exact effect on coal production.

Ordinarily, improvements made in and around coal mines can only be placed in one class—that of essentials or necessities. The custom of many well organized companies is to make yearly budgets which embrace all expenditures for improvements that can be foreseen for the year. These are then placed in two main classes—those that are imperative and those that are desirable, but that can be, if necessary, deferred for six months, or a year. Generally the first class of improvements includes equipment to maintain or increase output, but because of war conditions it has been necessary to include in it housing and other personal facilities for employees. This in some part is due to the increase in the larger number of older men employed who have families. Thus, in Utah, the operators have built a considerable number of dwellings for employees and have added more conveniences than heretofore. Perhaps it is not strictly just to attribute all this to war conditions, for the general policy all over the United States for several years past has been to make living conditions in coal camps more pleasant and comfortable.

During the year three large amusement halls were opened with great éclat, and the enlargement of another started. These halls have meant much to the inhabitants of the camps and have proved popular. All were commenced in 1917, but finished in 1918, as were also three large miners' bathhouses and some smaller ones. It has also become necessary to increase the garage facilities in many of the camps to take care of the ever increasing number of automobiles owned by miners. The custom has been followed in many instances of building central garages having 7 to 12 stalls. These are built of fireproof materials, possess low fire risks and improve the general appearances of the towns.

It is now becoming inappropriate to speak of some mining communities as "camps," for at least two are incorporated towns boasting of mayors, town councils, boards of health, town constables and sprinkling wagons. In one, at least, the citizens have a cement sidewalk and have planted shade trees along the streets. Civic pride is being developed, the manifestation of which is apparent in the much more tidy appearance of the various municipalities.

The carbon dioxide recorder used in testing the working of steam boilers should be made to pay dividends, says *Power*. This indicator does not of itself improve the efficiency of the plant, but merely shows what is being accomplished. Every engineer should be acquainted with the operation of the instrument so that he may use the information it gives to aid in the economical combustion of coal. Low CO_2 readings may be caused by excess of air or improper mixture of air and gases. Excess air may be caused by leaks in the boiler setting, carrying too thin a fire bed or too strong a draft. Low CO_2 is also caused by insufficient air or too little draft; the fuel bed may be too thick or the air spaces in the grate may be clogged with clinker or slag. Leaks about the furnace or boiler and dirty tubes or flues retard the draft. However, one of the most common causes of insufficient draft is the clogging of the grates with clinker or melted ash.

Rolls for the Preparation of Coking Coals

SYNOPSIS—*Coal is frequently crushed at coking plants in order to secure uniform and homogeneous coke. For this purpose two general types of machines are available—the hammer mill and the roll crusher. The latter appears to possess certain advantages over the former.*

THE increased attention being given in this country to the preparation of coal for coking will insure considerable interest in any details that may be available regarding the many questions raised in connection with this important problem of producing a uniform coke for metallurgical use. This article will be a description of rolls with smooth and corrugated surfaces used for sizing bituminous coal preliminary to coking.

Coking coals are crushed (1) so as to detach adhering impurities from the real coal. Preliminary to separating the worthless matter from the good by a dry or wet method of cleaning; (2) so as to reduce the non-coking impurities intermixed with the coal small enough that the resulting coke will be uniform in structure and not contain detrimental cracks or parting seams; (3) to prepare coking coals of different physical and chemical characteristics, preliminary to making a uniform mixture for charging.

The insertion in this article of data relating to hammer mills is only for the purpose of comparison, in order to learn the relative value of rolls, and show that each type of coal-reduction equipment has a field in which it excels.

Hammer mills will pulverize run-of-mine coal without preliminary sizing. In the use of rolls it is essential that the coal be sized small enough so that the largest pieces will catch between the rolls.

Rolls and hammer mills are the two distinct types of machines extensively used for preparing coal for coking. Since it is possible to purchase either type of machine in almost any size and with the assurance that the design and construction are adequate for the work intended, the choice of type can be made strictly on the basis of suitability and economy.

There are certain advantages and disadvantages that are inherent in each type of machine, and these are generally well recognized. Of greater importance, and less generally appreciated, are the characteristics of each machine for a particular size and service.

Hammer mills pound and force the coal through perforations or longitudinally placed bars, the size and spacing determining the size of the largest pieces of the coal. Rolls crack the coal by compression and no interfering impediment obstructs its free passage from the machine after passing between the rolls, the distance apart the rolls are set determining the size of the largest pieces of the coal. The difference in principle of reduction evidently results in a considerable saving of power, in favor of rolls, that is worthy of consideration in making a choice of types on the basis of economy of operation and repair. Cracking the coal by compression in place of pounding and forcing it through a certain size of hole, results in a more uniform and better product for the effective operation of the succeeding cleaning method. The pounding and forcing action creates an excessive amount of fines and dust from both the impurities and the coal, which increases the difficulties involved in any cleaning method on a commercial scale or of separating the worthless matter from the valuable coal. It also adds to the difficulties of clarifying the wash water of refuse.

Since rolls act on the principle of cracking by compression and since, when they are set to crack the coal to any particular size, the particles smaller than that size can tumble through without being further reduced, rolls yield a smaller percentage of fines and dust and a more uniform finished product for the final cleaning or charging than any other type of coal-reduction machine. Rolls will crack wet coal as satisfactorily as when the coal is dry without increase in the absorption of power and without choking. Approximately 25 per cent. less power is required with rolls than with any other type of reduction machine to reduce like coal to

NOTES—Coal designated as soft and friable is Pocahontas coal. Coal designated as hard and tough is Pittsburgh gas coal. In each case the run-of-mine coal had been first sized by a Bradford coal breaker with 1¼-in. square perforations. The tonnage fed per hour is the maximum, with the designated diameter, length, surface, speed and distance rolls set apart. Speed of rolls great as permissible, without choking by the refusal of rolls to nip the largest pieces of coal. Rolls designated as corrugated have three corrugations to one inch, 3/16 in. deep.

TABLE II. RECORD OF TESTS MADE WITH HAMMER MILLS, AT COMMERCIAL COAL-PREPARING PLANTS

NOTE—The tests were made immediately after the mills were installed. Coal designated as soft and friable is Pocahontas coal. Coal designated as hard and tough is Pittsburgh gas coal.

the same degree of fineness. The upkeep and depreciation per ton of coal handled is barely noticeable owing to the few parts subjected to wear and tear. In case of choking up rolls can be relieved promptly without derangement of the covering. They are practically dustless and operate at a comparatively slow speed, have a large capacity per square foot of working surface and a minimum of skill and attendance is required. Instant and rigid adjustments may be secured in the space between rolls; automatic adjustments for instantly relieving the rolls in case tough foreign matter is mixed with the feed may be employed as well as a magnetic attachment for the removal from the feed of nails, nuts, mining-machine cutters and the like. A positive automatic feeding device to prevent overloading may be employed, while regrinding of smooth rolls when they have become unevenly worn can be accomplished without removing the rolls from their supporting frame. Rolls are comparatively reasonable in price and cost of installation.

The relation between the maximum size of coal fed to rolls, the speed at which they revolve, the diameter and the space between them determine the angle of nip. Rolls cannot be fed with run-of-mine coal as can hammer mills, but must be supplied with a sized product, the largest pieces being of a size suitable to the angle of nip provided. With a spacing of $\frac{1}{16}$ in. in the clear, and a peripheral speed of about 1500 ft. per minute, the relation between the diameter of rolls and maximum size of individual pieces of coal are as follows:

Diameter of rolls 24 in. for ¾ in. cubical form of lump and less
Diameter of rolls 30 in. for 1¼ in. cubical form of lump and less
Diameter of rolls 36 in. for 1½ in. cubical form of lump and less
Diameter of rolls 42 in. for 2¼ in. cubical form of lump and less
Diameter of rolls 48 in. for 3 in. cubical form of lump and less

When coking coal is to be charged without removing a portion of the worthless matter by cleaning, and fineness is desired only for mixing coals of different characteristics, or to reduce the intermixed impurities to a size such that the resulting coke will be uniform in structure, some coke-oven operators are of the opinion (and this is substantiated by record of comparative tests on file) that rolls will not produce as large a percentage of fine coal as hammer mills. The record of tests which has induced this opinion is not questioned, but other conditions, perhaps unnoted, occasioned such misinterpretations.

For example: Table I, line 9, shows that rolls set $\frac{1}{16}$ in. apart, handling soft and friable coal, produce a product of which 87.25 per cent. passes through a hand testing sieve provided with ⅛-in. round holes. Table II, line 2, shows that a hammer mill provided with a screen having ¼-in. round perforations, handling soft and friable coal, produces a product of which 97.10 per cent. passes through a like sieve. Upon examination of the products remaining on the testing sieves, it was ascertained that the roll product (12.75 per cent.) consisted of about 30 per cent. coal and 70 per cent. impurities, thin and rectangular in shape, averaging $\frac{1}{16}$ in. thick, ⅜ in. wide and equally as long; or in volume 0.0087 cu.in. The hammer mill product (2.90 per cent.) consisted of about 65 per cent. coal and 35 per cent. impurities, cubical in shape, averaging $\frac{7}{32}$-in. cubes; or in volume 0.0105 cu.in., or a difference in volume of 0.0018 cu.in. in favor of the roll product. The coke made from each product was uniform in structure and free from cracks or parting seams, experts declaring that no difference whatever existed in its physical characteristics.

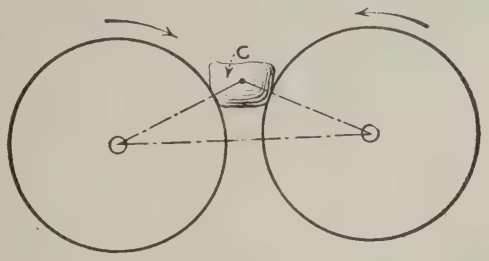

FIG. 1

FIG. 1. TOGGLE JOINT ACTION OF ROLLS

The unnoted conditions previously mentioned regarding the misinterpretations of coke-oven operators, relating to the comparative fineness of coal produced by each type of machine, are found in the difference in symmetry of dimensions of the products, revealed by testing these products for fineness on similarly perforated testing sieves. To make comparative tests useful and avoid erroneous conclusions, testing sieve perforations should have the same area, but conform in shape to the product from each type of machine. For hammer mill tests, round or square perforations should be used to conform to the cubical shape of the product, while for roll tests they should have rectangular perforations to conform to the rectangular shape of the product. If each product is properly tested there will be only a slight difference in the fineness of the two products, or in volume of individual pieces; provided both machines are maintained in operating condition.

The only advantage hammer mills appear to have

over rolls for preparing coking coal lies in their ability to crush run-of-mine and large coal; however, it is now considered economical to first size large coal, to a considerable extent, by means of Bradford breakers. Such preliminary sizing not only lessens the power required by the mill but removes any large and tough foreign matter mixed with the raw coal that might damage succeeding units of preparation. The chief disadvantages of hammer mills are the cost of frequent adjustment and renewal of the working parts, and the absorption of power necessary to force the crushed coal through the screen perforations or spaced bars.

Tables I and II show records of tests made with hammer mills and rolls, at commercial coal-preparing plants, in connection with byproduct coke ovens. The record of hammer mill tests, Table II, line 1, the mill having ⅜-in. round perforated screen, crushing soft and friable run-of-mine coal, shows that 91.30 per cent. of the product passed through a ½-in. round-hole testing sieve. The crushing operation required 0.814 actual horsepower-hour per ton of coal. Line 4 shows that the same mill, when crushing hard and tough run-of-mine coal, produced a product only 86.20 per cent.

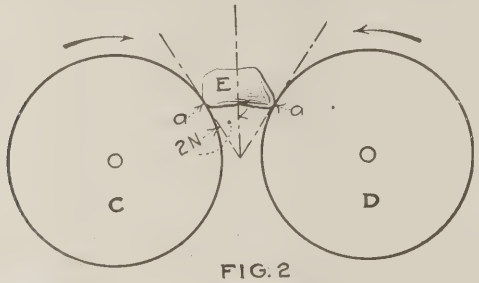

FIG. 2

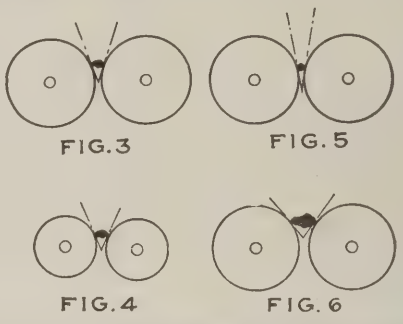
FIG. 2. THE ANGLE OF NIP



of which passed through a like sieve. Here the crushing required 0.886 actual horsepower-hour per ton of coal. Thus a difference of 5.10 per cent. in the fineness of product and 0.072 hp.-hr. in power requirements is shown. This signifies that the soft and friable coal was crushed finer and required less power.

The record of roll tests, Table I, line 9, the machine cracking soft and friable sized coal, shows 87.25 per cent. of the product passed through ½-in. round-hole testing sieves, and that 0.65 actual horsepower-hour per ton was required. Line 10 shows that when the same rolls were cracking hard and tough sized coal 85 per cent. of the product passed through a like sieve, and 0.75 actual horsepower-hour per ton was consumed. This reveals a difference of 2.25 per cent. in the fineness and 0.10 hp.-hr. in the power requirements, signifying that the soft and friable coal was cracked finer and required less power.

If the operator making the tests had used a sieve with perforations of the same area as the ½-in. round-hole sieves employed, but rectangular so as to conform to the shape of the roll product, the percentage of fines produced by the rolls would have been shown to be as much if not more, while the individual pieces would have been found less in volume than those produced as above mentioned by the hammer mill and as shown on Table II, lines 1 and 4.

In discussing this question of crushing under different conditions there are four factors to be considered: (a) Compressive strength of material; (b) extent of crushing desirable; (c) work or power required for crushing; (d) comparison of various machines.

There are four ways that force may act in crushing coal or other material: (1) By direct pressure as between rolls where there is a strong force acting at low velocity; (2) by a blow on an anvil, as in stamps, where there is a medium force acting at a moderate velocity; (3) by a blow in space, as in the hammer mill or Carr

FIGS. 3 TO 6. COMPARING ACTION OF ROLLS

disintegrator, where there is a weak force acting at high velocity; (4) by grinding, as in the amalgamating pan. In the first three cases the force acts perpendicularly to the surface to produce rupture by compression; in the last case it acts obliquely, producing rupture by compression combined with shearing.

Crushing rolls act upon the lump *C*, Fig. 1, on the principle of the toggle joint. The revolving rolls being held in position in their journals, act radially upon the lump, gradually drawing it toward the narrowest space between them and finally breaking it by virtue of a compressive force superior to the breaking strength of the lump. The lump is therefore broken by compression. The spaces between rolls vary from rolls close together up to ½ in. apart. The relation between the diameter of lump fed to rolls and the space between them, that is to say the amount of reduction, is highly important if rolls are to do their best work.

If the rolls *CD* (Fig. 2) be fed with a lump of coal *E*, the tangent to the rolls at *AA*, the point of contact

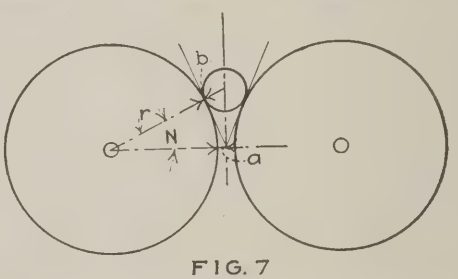


FIG. 7

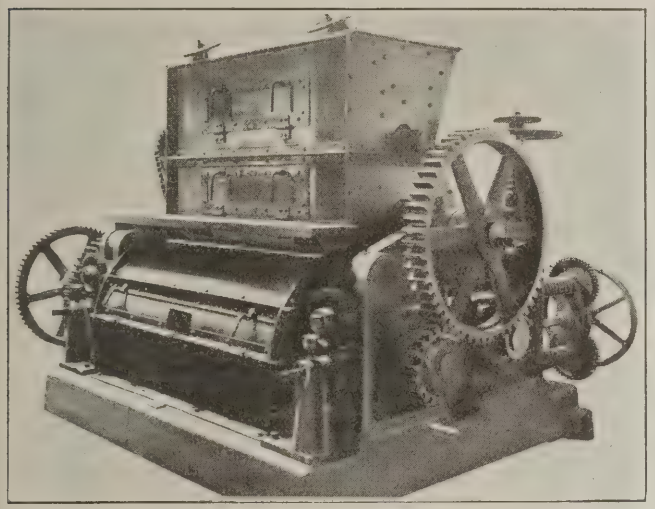
FIG. 7. THEORETIC ACTION OF CRUSHING ROLLS

with the lump, meet below, forming an angle $2N$, the half of which N is called the angle of nip. This angle may have values from 0 deg., where the space between rolls is as large as the feed lump, increasing until the angle is so large that the rolls cannot nip the fragments. This angle of nip in any case will depend for its value upon the diameter of the rolls, the diameter of the lump fed and the distance in the clear at which the rolls are set. It is affected by the following factors: It is diminished by increasing the diameter of the rolls, by increasing the space (clear

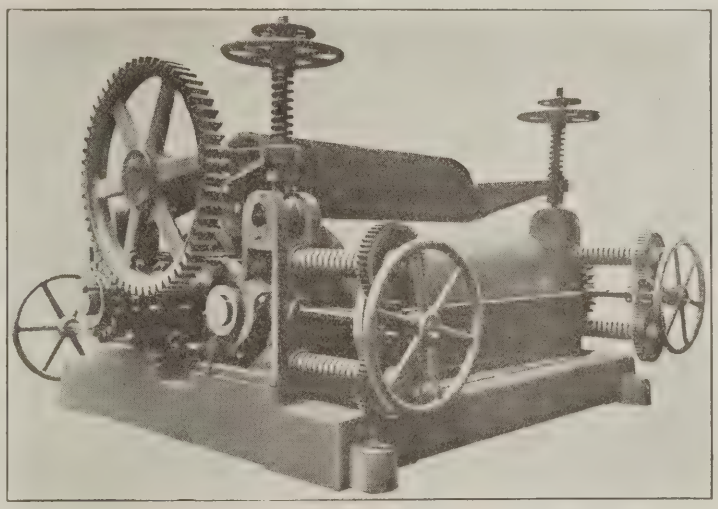
distance) between the rolls, and by diminishing the size of the lumps fed to the rolls.

A comparison of Figs. 3 and 4 shows that large rolls, acting on a given size of lump, have smaller angles of nip than have small rolls. Figs. 3 and 5 show that larger spaces give smaller angles of nip. Figs. 3 and 6 show that smaller lumps give smaller angles of nip.

There are two values of this angle of nip which are of special interest; namely, when its value equals the angle of friction, and the rolls do no work; and when its value becomes the practical angle of nip, at which rolls will work satisfactorily. The angle N, Fig. 7, becomes the angle of friction when it is of such a value that a sphere fed to the rolls will just slip upon the points of contact and therefore fail to be crushed.



All relations between size of feed, space between rolls, radius of rolls and angle of nip can be expressed by a simple formula, which is derived as follows (see Fig. 7): If b = radius of sphere to be crushed, a = $\frac{1}{2}$ space between rolls, N = angle of nip and r = radius of roll = $\frac{1}{2}$ diameter, then



$$\frac{r + a}{r + b} = cosine\ N$$

Theoretically, increase of speed, provided the reduction in size is sufficiently slight, can be made to almost any limit; but practically, high speed with any considerable reduction will give trouble, owing to the refusal of the rolls to nip or take hold of the lumps. These fly back until a dangerous amount collects and then the rolls choke. This may be explained as follows: A lump of coal falling under the influence of gravity from heights of 6, 12, 18 and 24 in. will have final velocities of 340, 481, 589 and 681 ft. per minute respectively. Now, if the rolls are revolving at 900 ft. per minute peripheral speed, then a certain part of the friction must be used to accelerate the lump of coal to this speed before it will be nipped. This amount will be greater or less according as the peripheral speed of the roll exceeds the velocity of the particle by much or little. The use of a part of the friction for the purpose of accelerating the particle does not in itself prevent the particle from being finally nipped, but merely delays the nipping action. It is this delay during the time necessary for accelerating the particle which prevents the nipping, for until accelerated to the speed of the rolls the particle is necessarily slipping and this slipping smooths the surface to a certain extent which causes the coefficient of friction to be reduced and prevents the particle from going through.

Rolls of large diameter apparently possess three advantages over those of small diameter: (1) The increased surface allows more feed to be crushed with a single pair of rolls, but the gain is not important unless the renewals in the case of the smaller rolls are so frequent as to cause serious delay and added cost. The wear of rolls per ton crushed would probably be the same in both cases. (2) The larger rolls can make a greater reduction in size of lump, the angle of nip and the peripheral speed being the same in both cases. (3) Larger rolls have a greater capacity than smaller ones, the reduction being the same, since they can be run at a higher rate of speed on account of their more advantageous angle of nip. In case both the reduction and peripheral speed are the same for the large and small rolls, the large rolls will make the reduction more gradually and hence with less shock.

Some authorities advocate running one of the rolls slightly faster than the other in order to prevent the exact mating of the rolls with a consequent possible unevenness of wear resulting therefrom. This is especially true with geared rolls. The use of any considerable differentiation of this kind to produce grinding, with a view of increasing the crushing power, has been proved fallacious on hard brittle materials, since such an action requires increased power without corresponding benefit. In regard to soft and friable material, however, the case is different. The material which is soft, when crushed by smooth rolls running at equal speeds forms ribbons or pancakes, while a differential adjustment tears the material apart, completely overcoming this difficulty.

FIGS. 8 AND 9. A ROLL CRUSHER INCASED AND WITH COVER REMOVED

WATER-POWER HAS been used widely in industry, but it has not entered into serious competition with coal. Rather it has conserved coal for special uses in notable instances. For example, a large hydroelectric power plant in the anthracite field of Pennsylvania distributes current over a big section and releases hard coal for use in cities where smokeless fuel is at a premium.

New England Coal Dealers' Convention

SPECIAL CORRESPONDENCE

SYNOPSIS — *Retailers devote two days to exchange of views. "Coöperation," the chief note. John E. Lloyd, of Philadelphia; George H. Cushing and Arthur F. Rice, of New York, the leading speakers. Dealers impressed with need of taking coal liberally in the spring.*

THE "Victory Convention" of the New England Coal Dealers Association was held at Worcester, Mass., Mar. 19-20. The attendance at this seventeenth annual meeting broke all records, showing that retail dealers are keenly interested in coöperation and are eager to have the benefit of the best opinion and advice in facing their various problems. The ballroom of the Hotel Bancroft was admirably adapted to the use of such a gathering; the speakers were easily heard, and there was an absence of that constant going in and out that so often mars the proceedings of trade conventions. After the dealers had been welcomed by Mayor Holmes, the first session was devoted to reports that were of unusual interest.

WILLIAM A. CLARK
President of New England Coal Dealers Association

William A. Clark, of Northampton, Mass., the many-times-elected president of the Association, paid high compliment to the Worcester Fuel Committee and to the dealers of that city who distinguished themselves by their cordial and complete coöperation last year in handling the local situation. The efforts of the Association officers to be of real service to the New England Fuel Administration were also mentioned, and prominence was given a memorandum recently sent Mr. Clark by Cyrus Garnsey, Jr., a retail coal dealer of Memphis, Tenn., and assistant to Harry A. Garfield. Mr. Garnsey strongly urged the retailers to retain the great advantage that organization had been to them during the war, and he also recommended that they enlarge the scope of their association to include some of the activities that the Fuel Administration has been obliged to give up.

The address of John E. Lloyd, vice president of the National Retail Coal Merchants Association, was received with the closest attention. Mr. Lloyd was in good voice and made a deep impression. "Every successful business," he said, "must be organized nationally, and no business can be successful if it is not organized nationally. A lesson must be learned from the thorough organization of labor, whose representatives are heard in the highest circles of government.

"The organization of business men," continued Mr. Lloyd, "can do a great deal to make union labor helpful, rather than harmful. When the employer takes an active interest in labor organizations, instead of neglecting them and permitting distrust and discontent to increase, he gains results every time. In Chicago the plan of joint meetings of employers and employed has been a great success."

Mr. Lloyd then attacked price-cutting, referring to a dictum of the Federal Trade Commission that sales less than cost constitute unfair competition. "If the retail coal dealers would only make the same effort to get the maximum price for their product the benefit to the industry would be widespread." In closing, Mr. Lloyd urged the dealers to discourage direct sales to consumers outside the usual trade channels, and to bring their influence to bear against the practice of employers selling coal to their operatives at cost. The Fuel Administration had taught coal dealers not only how to organize, but to figure costs and to that extent the dealers had been helped materially in 90 per cent. of the cities. The convention was enthusiastic in its approval of Mr. Lloyd's address.

The dinner in the evening was attended by nearly 700 persons—the dealers, their ladies and friends. There were stunts and cabaret in bewildering sequence, while at intervals the big company joined in singing popular songs. The gathering was on so large a scale that in addition to the entertainment provided by the Worcester Coal Club there were several cases of local jollification that broke out in parts of the hall. After the tables had been cleared the scene resembled nothing so much as a four-ring circus. All the veterans wore their broadest smiles. A feature of the business meeting on Thursday forenoon was a question box, answers being made from the platform. After a brief talk by Jacob Asher on the need of supporting the War Savings Stamps campaign, George H. Cushing, Managing Director of the American Wholesale Coal Association, spoke on "Coal Dividends and Profits." Mr. Cushing outlined what he regarded would be the form of Government control to be exercised in future. Those in the industry should invite supervision in what he termed the right way. Mr. Cushing drew applause when he reminded the dealers that once more they were to have a buyers' market and that wholesalers could no longer be arbitrary in passing on to the retailer the onus of settling for cars lost in transit, short weight, and other details which he felt were purely matters for the original shipper to adjust.

After an informal luncheon served by ladies of the Worcester Coal Club, Arthur F. Rice, Commissioner of the Retail Coal Merchants Association of New York City, addressed the closing session, his announced subject being "The Needs of the Hour." Mr. Rice argued that prices ought to be lower for purely economic reasons. "With the present high prices," he said, "there is every inducement for substitutes. Electric companies strive to put current into all large buildings, and par-

ticularly the hotels of New York. Once the electric systems are installed no more coal will ever be used. Great business concerns are ready to spend hundreds of thousands of dollars to get people to use their products and thus lay the broad foundation for future business, whereas the future of the coal business is threatened with a huge and permanent loss. If the remedy for this bad situation is sought in the form of high prices, then I can see worse things ahead for the coal trade."

W. H. Williams, vice president of the Hudson Coal Co., spoke in general terms of the anthracite situation. He dwelt on the great urgency of keeping the mines in operation the coming spring and summer to avoid shortage in the fall and winter. Shutdowns at the collieries add tremendously to the cost of production.

The visiting dealers missed the short well-considered papers by well-informed retailers that were so valuable a feature of last year's convention, but the addresses given were timely and thoroughly appreciated.

The exhibit of mechanical contrivances for the use of coal dealers was held in the Casino. It was unusually complete, particularly in the display of self-dumping devices for coal trucks. The Providence Gas Co. and the New England Gas and Coke Co. through their interesting exhibits made special appeals to dealers to help market their byproduct coke.

Next year the Association will meet in Springfield.

Boiler Fuel Economy

By M. Meredith
Liverpool, England

From the average figures obtained from tests on 250 typical steam boiler plants in Britain, interesting data regarding the economy effected by the adoption of scientific methods in the boiler house have been obtained. Of the plants referred to only two gave efficiencies over 80 per cent., nine gave efficiencies from 75 to 80 per cent., 13 showed 70 to 75 per cent., 30 gave 65 to 70 per cent., 44 gave 60 to 65 per cent., 62 gave 55 to 60 per cent., 47 gave 50 to 55 per cent., while 43 gave less than 50 per cent.

The average working efficiency for the whole 250 plants was therefore 60.09 per cent. and, while 61 per cent. of the plants were working with an efficiency of less than 60 per cent., only 9.6 per cent. of the plants exceeded 70 per cent. efficiency. Again, 75 colliery steam boiler plants gave an efficiency of only 51.2 per cent. as compared with the average of 60 per cent. for the whole country.

For the purpose of making a calculation as to the possible saving of fuel by increased efficiency of the whole of the country's steam-raising plants, the average figure of the 250 plants investigated is taken as typical for all plants of the country. According to a recent report of the coal conservation sub-committee of the Reconstruction Committee, about 80,000,000 tons of coal are used annually for power production only. Deducting 15,000,000 tons used on railways, 65,000,000 tons remain, of which 90 per cent., or 58,500,000 tons, are used for power production through steam-raising. In many industries, however, much more steam is used for heating and general manufacturing processes than for power production.

It is therefore taken that the amount of coal used for steam generation in the United Kingdom is between 75,000,000 and 100,000,000 tons. If, then, the efficiency of the 250 plants tested, consisting of 1000 boilers, is 60.09 per cent., and the annual coal consumption of these plants is 2,166,000 tons, an increase in efficiency to 75 per cent. represents a saving of 430,000 tons. A similar increase in efficiency of the whole of the country's boiler plants would represent a saving of 20 per cent. of fuel, or of 15,000,000 to 20,000,000 tons.

Of the 287,000,000 tons of coal produced during 1913, 20,000,000 tons was consumed by the collieries themselves. Practically the whole of this coal provided steam for power to win the coal. This represents 7 per cent. of the total output. If these colliery plants were reorganized to run at 60.09 per cent. efficiency (the average for the country) a saving of 15 per cent., or 3,000,000 tons, would be effected. If they could be run on scientific lines so as to yield 70 per cent., a 27 per cent. saving representing 5,400,000 tons of coal per annum would result.

The question of coal economy is doubly important—first, as an immediate war measure, and secondly as part of a great national scheme of reorganization, essential to future progress. A plea has accordingly been made for the quick survey and reorganization by experts of all the boiler plants of the country, and the immediate reorganization of the largest as well the more inefficient plants, and those, too, which are always required to produce a large amount of steam for other purposes than power production. Such a reorganization will be in strict harmony with the future larger scheme of national coal economy.

Frank R. Weitzel Dead

On Feb. 26, 1919, Frank R. Weitzel, assistant general superintendent of the Phelps Dodge Corporation, Dawson, N. M., died of influenza-pneumonia. He had resided at Dawson for nearly 14 years, and was known to almost every man, woman and child in the camp. He was held in high esteem and respect by both his employers and employees of the company, and his popularity was further attested by the large attendance at his funeral. He was endowed with a cheerful and sunny disposition which endeared him to his many friends.

The deceased was born at Wilkinsburg, Penn., Feb. 16, 1881. He entered the employ of the Empire Coal Co. at Bellaire, Ohio, July 1, 1901, as a member of the engineering corps. Here he stayed until September, 1905, when he went to Dawson City, where he was mining engineer until 1913, when he became assistant general superintendent.

The deceased is survived by a widow and two children. A mother and a sister live in Florida. E. H. Weitzel, a brother, is manager of the fuel department, Colorado Fuel and Iron Co., Pueblo, Colo.

It has been estimated that the present annual production of hydroelectric power in the United States is about the equivalent of 40,000,000 tons of coal; 400,000,000 tons of coal is used yearly in the production of steam power and electric power generated by fuel. Of all the readily available water-power in this country, only about 10 per cent. has been developed; hardly 3 per cent. has been utilized of all the power which might be developed under proper storage arrangement. There has been little encouragement in the past for water-power development owing to our laws and the attitude of the law makers. A water-power bill has been brought up in Congress, and if it is enacted into a sufficiently liberal law it should stimulate development in this field.

Beehive Oven Supremacy Passing —But Not Yet Passed

By John L. Gans
Connellsville, Penn.

SYNOPSIS — *During the latter part of 1918 the output of byproduct coke exceeded that made in beehive ovens. It is doubtless true also that at present more byproduct coke than beehive is being made. Until the operative capacity of the byproduct plants equals or exceeds the similar capacity of beehive plants, however, it cannot justly be said that the byproduct type has gained supremacy. This condition will probably be reached in the coming autumn.*

ALTHOUGH the byproduct coke ovens of the United States gained supremacy over the beehive ovens in production in the closing months of 1918, and have maintained the lead more or less regularly since, an analysis of statistics and conditions would tend to confirm the belief that the former have yet to demonstrate their capacity to make more than 50 per cent. of the coke to be manufactured during the ordinary statistical period of a calendar year. This statement follows logically, if not convincingly, from a consideration of the fact that the outdistancing of the beehive oven has been more the result of trade conditions than of the development of the byproduct ovens to that point where they possess the physical preponderance of productive capacity.

Byproduct Plants Attain Maximum Capacity

In the last three months of 1918 the byproduct plants had attained their then maximum capacity and were holding it with only slight variations, such as were incident to interruptions in coal supply and similar considerations. At the same time the beehive ovens were combating the influenza epidemic and suffering a constant and steadily diminishing labor supply with a resultant gradual decrease in weekly output. Under these circumstances the beehive ovens yielded more readily than the byproduct to the deterrent influences on industry which followed the signing of the armistice and the removal of Government regulations on coal and coke. The merchant furnaces, feeling the necessity of curtailing operations to proportionately a greater extent than the other interests, merchant beehive coke operations were obliged to follow suit. The bulk of the byproduct ovens being associated with furnace plants, the rate of their operation was less seriously interfered with, hence the ability of the latter to maintain the lead in coke production, which was lost by the beehive ovens, not because the capacity of the former had exceeded the latter, but because of a combination of circumstances which had made the race an unequal one.

Whether a permanent handicap has thus been imposed upon the beehive industry, or its eclipse is but temporary, remains to be proved by the events of the current year. A study of the present situation is interesting, however, when considering what has come to be the generally accepted view that the leadership of the byproduct oven is even now absolute and indisputable. When considered in their entirety, and compared with 1917, the statistics of coke production in 1918, prepared by C. E. Lesher of the U. S. Geological Survey, merely show that the byproduct ovens made a further gain over the beehive as coke producers during the latter year. Only by a comparison of the weekly records —not the totals for the year—is the fact revealed that, with the exception of three weeks, the byproduct ovens led in tonnage only during the last quarter of the year. In January, 1919, beehive production made relatively the same weekly gain as the loss shown by byproduct ovens, the former thereby temporarily regaining their position as leader, which had been lost with the first week of October, 1918, when the production stood: Byproduct, 585,281; beehive, 574,000 tons. By the first week in February, 1919, the tables had been reversed and the byproduct ovens had regained first place. Since that date, upon which the collection of byproduct statistics under the Fuel Administration was discontinued, the exact status of the two divisions of the industry is not known, but the continued decline in output of the Connellsville region alone would indicate that the actual present lead of the byproduct ovens is greater than that prevailing at the close of the year.

COKE PRODUCTION IN THE UNITED STATES, FEB. 1, 1918—JAN. 31, 1919
(From Weekly Reports Compiled by C. E. Lesher, U. S. Geological Survey)

Week Ended 1918		Beehive Coke	Byproduct Coke	Total Coke	Week Ended 1918		Beehive Coke	Byproduct Coke	Total Coke

					1919				
July	6	579,000	502,666	1,082,000	Jan.	4	479,000	546,298	1,025,000
	13	680,000	506,451	1,186,000		11	538,000	541,600	1,080,000
	20	632,000	517,671	1,150,000		18	557,000	559,298	1,116,000
	27	616,000	523,899	1,140,000		25	575,900	558,876	1,134,300

Mr. Lesher's statistics for 1918 credit the beehive ovens with having contributed 30,406,000 tons, or 53.1 per cent., and the byproduct ovens with 26,264,000 tons, or 46.4 per cent., of the grand total production of 56,670,000 tons of coke. Compared with the record of 1917 the byproduct ovens gained 4.2 per cent. and the beehive ovens lost a corresponding share of their contribution to the coke output of 1918. This was about one-half the rate of gain made by the byproduct ovens

in 1917 over 1916. In the latter year the beehive production of 35,464,224 tons—the greatest on record—was 66.1 per cent. and the byproduct production of 19,069,361 tons was 33.9 per cent. of the total.

Taking the figures for 1918, the byproduct ovens are found to have lacked 2,071,000 tons, or 3.6 per cent., of having produced a half of the coke made during the year. This fact alone would indicate that they had some distance to go before they could rightfully claim to have gained the ascendancy. Hence, as pointed out, the respective totals of the two types of ovens for the year 1918 do not make apparent the fact that the long-held distinction has been wholly lost by the more primitive of the two types. It is by a study of the month-to-month production during the closing quarter of the year that evidence is found that, for the first time in the history of the coking industry, the byproduct ovens have produced a greater quantity of coke within a given period of time than the beehive.

COMPARATIVE COKE PRODUCTION IN THE UNITED STATES
1893—1918

Year	Beehive Ovens	Per Cent.	Byproduct Ovens	Per Cent.	Total Net Ton
1893	9,464,730	98.8	12,850	1.2	9,477,580
1900	19,457,621	94.7	1,075,727	5.3	20,533,348
1910	34,570,076	82.8	7,138,734	17.2	41,708,810
1915	27,508,255	66.1	14,072,895	33.9	41,581,150
1916	35,464,224	66.1	19,069,361	33.9	54,533,585
1917	33,167,546	57.8	22,439,280	42.2	55,606,828
1918	30,406,000	53.6	26,264,000	46.4	56,670,000

On Feb. 1, 1918, when the weekly statistics of byproduct production began to be compiled, beehive production was 470,000 tons and byproduct 366,073 tons per week. The former rose and fell alternately, with a general upward trend, until the peak of 680,000 tons was reached in mid-July. Byproduct production grew gradually as new ovens and plants were placed in operation, attaining 502,666 tons by July 1 and the maximum for the year of 585,281 tons during the first week in October, overtaking the beehive ovens for the first time. During that week beehive production was 572,000 tons. The difference, 13,000 tons, was comparatively slight as coke tonnages are figured, but it was sufficient to register the first outdistancing of the beehive oven by its rival in the race for supremacy.

While the production of both types of ovens declined after Oct. 5, the byproduct output exceeded the beehive by 20,000 to 50,000 tons, or more, from week to week, with the exception of the last week in October and the closing weeks of January. Beginning with the first week in February, 1919, the byproduct ovens had regained their lost ground and, from all information at present available, and the fact that beehive production had dropped to 436,000 tons by Mar. 1, would appear to have retained their supremacy.

Beehive Oven Has Seen Its Best Days

It is by giving consideration to the recent augmentation of the byproduct equipment and that in course of construction that the conclusion becomes inevitable that the beehive oven is certain to sooner or later lose first place as a producer of coke. But from an inquiry into conditions prevailing during the closing months of 1918 and the opening months of 1919, it would appear that on the basis of the existing available equipment of the two types of ovens the byproduct will not possess the facilities for permanently wresting the honors from the beehive until well toward the close of the year. What conditions in the trade may do, with respect to the relative activity of the two types, is a different proposition and lies in the realm of speculation.

The builders' capacity ratings of the byproduct plants completed and in operation in the United States on Dec. 31, 1918, was 35,211,000 tons per annum. Practice having shown that even under the most favorable conditions the byproduct plants, taken as a whole, cannot be counted to yield more than 90 per cent. of their rated capacity, on account of repairs and other causes interfering with 100 per cent. operation, the commercial productive capacity of these plants was, in round numbers, only 31,700,000 tons per annum, or an average of 609,000 tons per week. Beehive production, on a greatly reduced schedule of operation and with many ovens on the inactive list, was 30,406,000 tons in 1918, or an average of 584,615 tons per week.

Byproduct Capacity Shows an Increase

If it is assumed that the beehive ovens will on the whole do no better in 1919 than in 1918, the byproduct ovens available for operation on Jan. 1 would, if operated at 90 per cent. capacity, maintain an average weekly lead of 24,385 tons, or a total of 1,294,000 tons during the current year. But byproduct capacity has already been increased during the first two months of 1919 by the completion of 374 ovens which, on a 90 per cent. operating basis, should add 942,000 tons to the year's output by this process. In addition to the ovens placed in operation since Jan. 1 there are 1376 in process of construction, although work has been temporarily suspended on several plants. If, as expected, these ovens are placed in operation by Oct. 1, the commercial capacity of the byproduct plants at that date will be increased by 3,467,500 tons to a grand total of 36,109,500 tons per annum, or an average of 694,000 tons per week.

Even though that capacity be attained by Oct. 1 it will be only during a part of the year that the byproduct ovens will have the capacity to produce coke at a higher rate per week than was attained by their cruder competitors in their heyday. In 1916, which was the record year in the production of beehive coke, 65,605 ovens of this type made 35,464,224 tons, and 6607 byproduct ovens made 19,069,361 tons, or weekly averages of 682,000 and 366,718 tons respectively. Assuming equated time of six months as the period of maximum production of all byproduct ovens built and building, the output for 1919 would reach approximately 34,000,000 tons, or a weekly average of 654,000 tons, or 28,000 tons less per week than the beehive average in 1916.

Since 1916 the number of available beehive ovens has been considerably reduced and practically no new plants have been built. Operations during 1918 show, however, that even under the many and severe restrictions imposed by shortage of labor, transportation troubles and the like, the beehive equipment was able to make some creditable weekly tonnages, compared with the record average of 1916. The week of Apr. 13 with 672,000, Apr. 27 with 739,000, May 18 with 678,000 and July 13 with 680,000 tons were all in excess of the banner byproduct week—Oct. 5, with a production of 585,281 tons—and reasonably within striking distance of the weekly average of 1916, had it been possible to have speeded up to near 100 per cent. capacity in 1918.

The year 1919 began with probably less than 90 per cent. of the beehive capacity of 1916 available for operation and with less than 75 per cent. of such oven

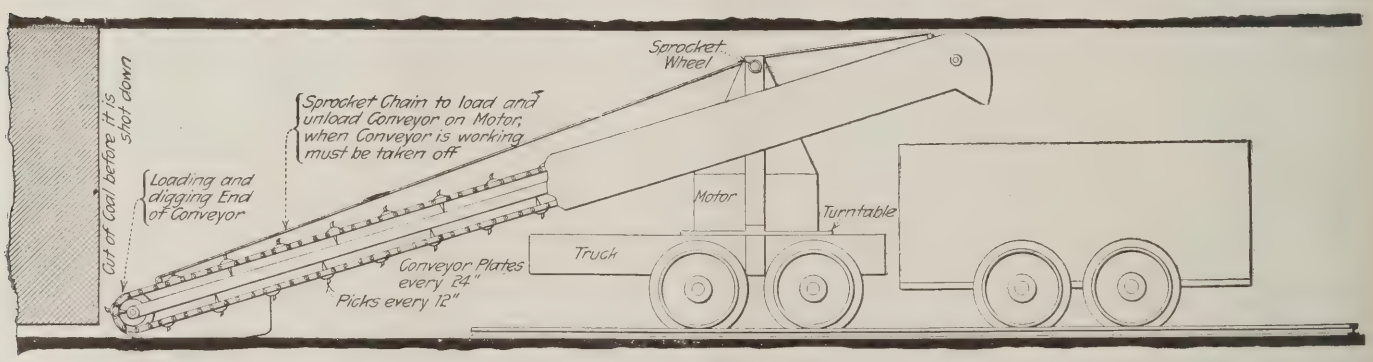
strength in blast. But with this curtailment in number and capacity a rate of operation equal to that in 1916 would still show the available beehive ovens capable of producing approximately 32,000,000 tons during the year, or an average of 614,000 tons per week, or about the same as the weekly average of byproduct ovens completed and in operation on Mar. 1. That 32,000,000 tons or more could be produced by the beehive ovens under favorable conditions during 1919 is fairly well established by the results of 1918 when 30,406,000 tons were produced when operating at much less than capacity of the ovens actually in use and with many serviceable ovens constantly out of blast.

It becomes apparent, therefore, that in point of productive capacity the lead of the byproduct oven over the beehive cannot be said to have been indisputably established until the capacity of byproduct ovens in operation has become equal to the task of making an average of more than 614,000 tons of coke per week, or a total of more than 32,000,000 tons within a twelvemonth. This can be attained when ovens now building have come to full production, but until this is an actuality the humble beehive can claim its ability to turn out the greater volume of coke if trade conditions will only provide the incentive and the opportunity to show what can be done.

Proposed Coal-Loading Machine

By H. R. Kirkbride
Allegheny County, Pennsylvania

NOW that the great war is ended and the world's markets will soon be opened up for competition, it devolves upon us to show our supremacy as the leading business nation of the world; to not only "be on the way," but to be "there with the goods" in quantity and quality, and at a price that any and every customer shall have no cause to question.



I will acknowledge that we have about reached the point of perfection in regard to ventilation, haulage, drainage and undercutting of coal, but I fail to see where we have made any progress worthy of mention in loading coal at the working face. We here employ the same old puffing and blowing, cursing and sweating, shoveling and scraping, with a little old-fashioned hand shovel, the same as our great grandfathers used when they were boys and worked in the mines. And if these old miners could come back again just to make an inspection, no doubt they would tell us that there was only one important thing about the mines that had us stuck, and that would be we shoveled and loaded coal at the face today in exactly the same way they did.

The question to me is this, and it seems to have got lost or strayed away from coal mining:

If it is economical for a coal operator to spend $1000 on a machine to undermine the coal and save 15c. on the cost per ton mined and double the amount produced, why would it not be economical for that same operator to spend $2000 on a machine to load that coal and save 30c. on the cost per ton loaded and likewise double the amount of coal produced? I have often heard it said that the cheapest thing that the mine owner had about his mine was the workingman. This might have been true in days gone by, but I could not accept it for the truth today.

In mines where the coal is 5 or 6 ft. thick and undermined with punching machines, the undercut is snubbed down. At the front the cut is 12 or 15 in. high and tapers down to about 3 in. at the back. The cut is 5 or 6 ft. deep. When the cutting is completed and the coal is blasted down, it falls away from the roof and the solid face of coal behind the cut. It is here broken up in fairly good shape for loading into the pit cars.

When the coal is mined and prepared for loading in this manner, I cannot see why loading machines should not be employed, more especially when we know that two men with a machine like the Myers-Whaley or the Halby shoveling machine can load as much as 200 tons per shift. By installing machines to load coal fewer men would be required to obtain a given output, because with machines to undermine the coal and machines to load it about two or three working places is all that would be required to keep these machines in steady operation without much moving about. One place would be getting cut while the other was being cleaned up, and *vice versa*. More coal would be produced with less rail, wire, pipe and other supplies, while lost motion would be cut down to a minimum in hunting around for a car of coal, as is often done in the mines nowadays.

SIDE VIEW AND PARTIAL SECTION OF PROPOSED COAL-LOADING MACHINE

I would not expect an ordinary shoveling machine built after the steam-shovel type to be successful where the coal is undercut with chain machines, because the coal remains too compact and solid even after it is shot down, so that the kind of a machine necessary in order to be successful in loading coal after chain machines must have the combined principles of digging and pulling the coal loose, shoveling it up, while at the same time it must convey and elevate it to a dumping point above the top of the pit car.

I herewith present my ideas of a machine which, if built and put to work, I feel sure would be a success.

In mines where the coal is 4 to 6 ft. thick and undercut with chain machines, the cut is generally 6 ft. deep and not more than 4 or 5 in. high from point to back. It takes more powder to blast this coal down than if it had been undercut with a punching machine; that is, to break it up so that it can be loosened sufficiently with a pick by the miner so that he can load it. If the average miner loads ten tons of coal per day after chain machines, he is working reasonably well. It would take a man two or three days to load out a cut as above described in a room about 25 ft. wide. Two men operating the machine shown in the accompanying illustration would clean up such a cut in about 2 hours, because with the conveyor built with an average working pitch of about 3 in. to the foot and the conveyor 18 ft. long and operating at a conveyor speed of about 200 ft. per minute and with blades 3½ in. deep, 2 ft. wide and spaced 2 ft. apart, this machine theoretically would deliver approximately 2 tons per minute. This obviously would be an impossibility in practice, but suppose that by reason of moving from one room to another and on account of the time that the conveyor would be stopped to change cars, throw off large pieces of bony, set posts, wait till butt shots were fired, etc., it would only be able to get, say, one-eighth of its theoretical output as good practical work. This would equal about 120 tons of coal loaded per 8-hour day.

To load by hand 120 tons of coal at 51c. per ton would cost $61.20; then, if two men were paid $10 each to run this machine and load 120 tons, there would be a clear saving of $61.20 — (10 × 2) = $41.20. Thus by using this conveyor coal would be loaded for less than 17c. per ton instead of 51c. as now, and this would be done with less hard work and more satisfaction.

This kind of machine, if built light and detachable from the truck, with the motor built compactly on one side of the conveyor instead of underneath it, could be used to load coal in any mine where chain machines are used for undercutting. I have seen coal as low as 2 ft. 3 in. thick cut regularly with chain machines.

A machine of this type could be built at almost any mine blacksmith or machine shop where chain machines are used. I have often noticed large pieces of sheet steel, sprocket chains, sprocket and gear wheels, car wheels and axles, cutting machines and locomotive motors that were not in use. A sorting out of the junk pile, a little time and patience and a good mechanic is about all, in my opinion, that would be required to build a loading machine of this character. I will here leave this problem for someone else to handle who may be in better shape and equally as anxious as myself to see progress made in coal mining.

THE CAUSE

Written Expressly for COAL AGE

BY BERTON BRALEY

BOLSHEVISM grows out of bitter woes.
It's a weed that tyranny has sown.
Exploitation, greed, fertilize the seed
Till a noxious jungle-plant has grown.
Ruthlessness and force cannot stop its course,
They but make it tower to the skies;
But where Justice reigns over men's domains,
Bolshevism withers up and dies!

IF it rears its dread, monstrous hydra-head,
Search the social system for the cause.
Where it waxes strong there is something wrong,
Wrong about the methods or the laws.
Bolshevism comes out of rotten slums,
Ignorance and want and discontent;
These things make it thrive, grow and keep alive,
Till it looms immense, malevolent!

BOLSHEVISM'S clutch loosens at the touch
Of the hand of Justice and of Right.
It will perish where life is fair and square,
Cease to be a menace and a blight.
Look, then, to yourself; let no greed of pelf
Blind you to the fact you may not doubt.
Guns will never cure—here's your weapon sure,
Justice put the Bolshevist to rout!

SNAPSHOTS IN COAL MINING

FIVE DOLLARS FOR BEST MINE PHOTOGRAPH

A READER can oftentimes obtain more information from a rapid glance at an illustration than from a laborious reading of paragraph after paragraph of mere descriptive matter. The illustrations accompanying the write-up of a new mine plant, for instance, help convey the story; used in conjunction with a well prepared article, they are an invaluable aid to proper understanding. All this is by way of preamble to a confession. *Coal Age* is meeting with ever-increasing difficulty in obtaining photographs of general interest and technical value to colliery men. So we want to enlist the aid of every reader of this paper. To stimulate interest in this matter, the editor of *Coal Age* will pay $5 each week for the best photograph sent in by any subscriber. Prints submitted must be for the exclusive use of *Coal Age* and must not have been previously published. All photographs not awarded the $5, but accepted for publication, will be paid for at a liberal space rate. The sender's name and address, with a brief description of the picture, must accompany each photograph. All prints will be returned, if desired.

Practical Miners' Course of the University of Kentucky

Many readers of *Coal Age* will be pleased to know of the progress made in the teaching of practical coal mining, during the past decade, at the University of Kentucky, at Lexington. In December, 1907, the Board of Trustees of the University established an eight-weeks' course for practical miners, at the request of Prof. C. J. Norwood, then dean of the College of Mines and Metallurgy. In June, 1918, Professor Norwood resigned his position at the University to accept the appointment, by the governor, as chief of the Department of Mines in Kentucky.

At that time the Board of Trustees of the University merged the three engineering colleges—College of Civil Engineering, College of Mechanical and Electrical Engineering and College of Mines and Metallurgy—into a single college known as the College of Engineering. Prof. T. J. Barr then succeeded to the position of professor of mining engineering and, as such, is in charge of the present eight-weeks' course for practical miners, which will open Apr. 1, 1919. Professor Norwood will be recognized standing in the front row, the eighth man from the right, and Professor Barr the fifth from the left, in the illustration.

CLASS OF 1918 IN UNIVERSITY OF KENTUCKY PRACTICAL MINING COURSE

There is every prospect that the class this year will be a large one, and Professor Barr has prepared an elaborate schedule covering the various subjects relating to the mining of coal. In the preparation of this course special attention has been given to the requirements of men desiring to present themselves at the examination for certificates of competency, as required by the state mining law. A point worthy of mention is the fact that the University has made instruction in this course entirely free, there being no charge even for matriculation.

Instruction is given by men who have had practical mining experience and been in daily contact with miners at their work and in their home surroundings. By reason of this experience and long association with the work of mining coal they are able to approach each subject from the viewpoint of the practical miner and present it more simply and clearly than otherwise would be possible. At the close of the course, May 24, each man that has done satisfactory work will be awarded a certificate of proficiency from the University.

For the convenience of those who live at a distance, but who desire to take the examination before the State Mining Board, which meets at Lexington, it has been arranged that the Board of Examiners will be in session May 26, the second day following the close of the course at the University. This arrangement will be greatly appreciated by those taking the examination, as it will avoid the necessity of their making an extra trip to Lexington for that purpose. Following is a copy of the schedule of instruction showing the several subjects taught in the course and the topic studied under each subject:

1. *Arithmetic.*—Instruction will be given in arithmetic, according to a man's needs, throughout the course.

2. *Coal Mining.*—(a) The different systems of laying out the workings, and the applicability of each, etc. (b) Blasting; dangerous and safe methods; "permissible" explosives; care and handling of explosives. (c) Timbering; principles and different methods; good and bad joints; computing the strength of pillars, distance between props, etc. (d) Sinking shafts and slopes; safety appliances for shaft and slope mines.

3. *Ventilation.*—Principles and methods; furnaces and fans; coursing, splitting, regulating and measuring the air current; use of anemometer, water gage, etc.; overcasts and undercasts; exercises in working out problems.

4. *Drainage.*—Siphons, pumps, air-lifts; setting pumps; laying pipe lines, etc.

5. *Mining Machinery.*—Haulage and hoisting; steam engines, gasoline motors and electric motors; compressed air; coal cutters, etc.

6. *Mine Gases.*—Nature, effects and indications of the presence of each; reducing dangerous conditions; exercises in problems. Illustrated with experiments, for which ample time has now been allowed.

7. *Safety Lamps and Testing.*—Principle of the safety lamp; care and use of safety lamps; methods of testing for gas. An excellent collection of various types of lamps is available for use in explaining the features of different makes. Natural gas is used for practice in detecting "caps" on the safety lamp.

8. *Explosions.*—Causes and safeguards; management of dust.

9. *Mine Fires.*—Causes and management of fires; reopening workings after a fire.

10. *Rescue and Relief.*—Methods of procedure after an explosion; organization of parties; dangers to be guarded against; temporary ventilation; expedients for carrying the air through the mine; use of rescue apparatus.

11. *Surveying and Map Drawing.*—Use of surveying and leveling instruments; putting up sights, marking off rooms at various angles; laying off curves, etc.; drawing the mine map; making blueprints. Men may devote all the course to surveying if they so desire.

12. *Kentucky Mining Law.*—A thorough drill in the mining law is given, and the formation of mine rules is discussed.

Operators Insist on Stabilization of Coal Prices

It is evident that coal operators who met with the Industrial Board Mar. 26 and 27 convinced the majority of the members of the board that the National Coal Association is right in its stand in insisting that the Government agencies which use fuel must be a party to any agreement involving the lowering of prices and their stabilization. Chairman Peek, of the Industrial Board, was taken by surprise at the attitude of the Railroad Administration. At the outset, he apparently was of the opinion that the Railroad Administration would be a party to any stabilization program which might be agreed upon. The coal operators, however, had had more experience with the Railroad Administration than had Mr. Peek. They insisted that the Railroad Administration commit itself in a definite manner. When it came to giving positive assurances, it became apparent to all that the Railroad Administration was reluctant to depart from its practice of buying coal as cheaply as possible without regard for the effects on the industry, labor and the general public.

Two significant events of recent occurrence convinced the operators that they must take a determined stand in their relationships with the Railroad Administration. In the first place, they had seen the splendid spirit displayed in the announced railroad fuel policy of the Director General disregarded in practice by his subordinates who have in charge the actual purchases of the necessary coal. In a public statement given to the press, the National Coal Association declared that "the Railroad Administration has adopted unfair practices which would drive the price of railroad fuel below the cost of production." In the second place they had learned that the steel manufacturers had discovered, to their regret, that the Railroad Administration feels in no way bound to buy rails at the stabilized price agreed upon with the Industrial Board. These instances led to the adoption of the following resolution:

Resolved by the representatives of the bituminous coal operators of the United States, in meeting assembled in Washington, Mar. 27, 1919, at the request of the Industrial Board of the Department of Commerce, acting in conjunction with the United States Fuel Administrator, that the operators of the country declare themselves ready to go into conference with the Industrial Board with a view to coöperating with the Government in stabilizing prices of bituminous coal during the readjustment period upon their being assured by the Industrial Board that the United States Railroad Administration and other Governmental agencies purchasing coal are also willing to coöperate.

While the discussion centered largely round the Railroad Administration, because the railroads take one-third of the bituminous production of the country, other Government purchasers of coal are held to be in the same class. The Navy's purchases, for instance, are of the greatest importance to the Pocahontas district. The Army will continue to be a large consumer for many months to come. The Interior Department maintains a central coal yard in Washington from which all the Government departments are supplied. The operators contend that no price stabilization could hope to amount to anything unless the Government itself buys at the terms that it arranges for other consumers.

As an evidence that the Industrial Board recognizes the validity of the stand taken by the coal operators, it is understood that the President's cabinet is to be asked to pass upon a definite policy in regard to Government participation in the stabilization program of the Department of Commerce. It is understood that the President is to be consulted before such a policy is announced.

Asks Interpretation on Contract Clause for Railroad Coal

The Attorney General has been asked to interpret the contract clause which the President had inserted in all the contracts eliminating the payment of brokerage or commission on contracts obtained from the Government. The interpretation has been asked by the Railroad Administration. The action was taken as the outcome of conferences between George H. Cushing, for the American Wholesale Coal Association, and H. P. Spencer, of the purchasing division of the Railroad Administration. The clause is contained, of course, in all contracts for railroad fuel. This led Mr. Cushing to formulate the following questions, which are the ones which have been referred to the Attorney General:

Some mining companies employ their managers of sales on a salary and allow them a commission on all coal sold. This arrangement is covered by a contract between the operator and his sales manager, and involves the whole output of the mine. Would the existence of such a contract bar that operator from selling coal to the United States Government for the use of the Railroad Administration?

If such a mine should sell to the Railroad Administration, would it bar that sales manager from collecting his commission on that coal?

Some coal operators own mines in several fields. These operators have organized separate selling companies, which buy the coal from all these groups of mines or at least dispose of it for the mines on the same basis. Under Sec. 6, would such selling company be prohibited from selling coal to the United States Government for the use of the Railroad Administration?

A third group of mines, related but not identical, in ownership, disposed of its entire output to a selling company which is owned by the majority interest in the several mines. In some cases this selling company pays a fixed price per ton for this coal. In others it gets as its compensation a percentage of the selling price. In still other cases it is allowed a minimum fixed price per ton from the operators plus a portion of any price obtained in excess of a stipulated minimum. Is this selling company prevented by Sec. 6 from selling coal to the United States Government for the use of the Railroad Administration?

Another group of mines is owned by a railroad company. To satisfy a decree of the United States Supreme Court, these coal mines have sold their entire output to a separate selling company. This selling company owns the coal outright. Under Sec. 6, is that selling company prohibited from selling coal to the United States Government for use of the United States Railroad Administration? In a word, are the mines owned by the railroad prohibited from disposing of their coal to the owner railroad by reason of this contract of sale?

By far the largest percentage of the mines of the United States are small mines. The average production of coal per mine, in fact, is less than 500 tons a day. On the average, the coal-producing companies own less than two mines each. This means that the average operator of the United States has less than 1000 tons of coal a day to sell.

However, the average mine has a market extending over more than five states. It is impractical for an operator having less than 1000 tons a day to sell, to support a sales force large enough to cover five states or more and do so at the cost of sales which is not prohibitive. Therefore, the average coal-mining company depends upon some selling agency to distribute his coal. The wholesaler selected becomes responsible to the mine for marketing a hundred per cent. of its product. The wholesaler, sometimes, buys the coal at a fixed price per ton at the mine and gets his compensation by being able to get for the coal a higher price. In most instances, the wholesaler gets his compensation by agreeing with the producer to accept a fixed percentage of the selling price. In other instances the wholesaler gets his compensation by deducting a fixed amount per ton from the selling price on all of the coal. Such wholesaler is the selling department of the mine. Under Sec. 6 he is seemingly classified as a third party in the transaction. Does Sec. 6 prevent this wholesaler from selling coal to the United States Government for use by the Railroad Administration?

Are the coal mines which sell through such wholesaler prohibited by the fact of that selling contract from participating in the business of supplying the railroads with coal?

Ordinarily each railroad buys its normal supply of coal from a nearby producing mine. Sometimes—such as in pre-strike periods and in cases of a grave and general disturbance of the coal market—the railroad finds it necessary to get additional coal from a more distant field. In such cases the railroad has been accustomed to request wholesalers in coal to canvass the distant field and procure large quantities for them. The railroads under such circumstances have compensated the wholesaler in the customary way. Under Sec. 6, are the railroads prohibited from using this purchasing agent in this way?

In times when the supply of coal has been short in the past, it has been the practice of the railroads to avoid advancing coal prices upon themselves by saying that they were "out of the market." They knew, however, that a certain amount of coal was being shipped to market intended to be sold to them. They knew that this coal would soon be under demurrage and that the owner of it would be willing to sacrifice it in order to move it. Taking advantage of this situation, they have entered into a secret contract with a broker to purchase this "distress" coal for them and have compensated him in the customary way. Under Sec. 6, would the railroads be prohibited from using the broker in this way? Would the transaction be invalidated by the fact that the broker had been so employed and paid?

In many instances coal mines have gone into bankruptcy. They are managed by the court. The receiver has appointed one man to operate the mines and another to sell the coal. Both men are employed on a commission basis. Under Sec. 6, would the sales agent appointed by the court on a commission basis be prevented from selling coal to the United States Government for the use of the Railroad Administration?

In many cases a wholesaler in coal purchases for cash a given amount of coal per month from a mine without regard to whether it is the whole output of that mine or any fixed proportion of it. He thereby becomes the owner of that coal. Under Sec. 6, is he prevented from selling that coal at a profit to the United States Government for use of the Railroad Administration?

Navy Will Survey Alaska Coal Field

The Navy Department has announced that a commission, consisting of five members—three naval officers, a mining engineer and a geologist—will be sent to Alaska to ascertain what steps should be taken in connection with the development of the Matanuska coal fields.

The commission sailed with the vessels recently ordered to leave Puget Sound Navy Yard on Apr. 1 to patrol Alaskan waters. It will be under the direction of a line officer of rank and will include two junior officers, Sumner Smith, superintendent of mining in Alaska, and Theodore Shapin, geologist.

In the naval appropriation act, which failed of passage at the last session of Congress, was the following provision: "One million dollars of which, or so much thereof as may be necessary, may, in his discretion, be used by the Secretary of the Navy in mining coal or contracting for the same in Alaska, the transportation of the same, and the construction of coal bunkers and the necessary docks for use in supplying ships therewith, and the Secretary of the Navy is hereby authorized to select from the public coal lands in Alaska such areas as may be necessary for use by him for the purpose stated herein." With a view to reopening the whole matter before the next Congress the Secretary of the Navy ordered the present investigation.

Railroad Administration Would Retain Tidewater Coal Exchange

The Railroad Administration continues to insist on the retention of the Tidewater Coal Exchange. The principal reason is shown by the following figures setting forth the actual savings to the railroads:

Tonnage dumped	48,785,967
Number of cars dumped	967,800
Cars saved on gross detention basis	1,747,600
Saving effected on per diem basis	$1,048,560
Cars saved	47,035
Investment necessary to have procured 47,035 cars at $2900 per car	$136,401,500
Interest on above investment at 6 per cent	$8,184,090
Credits extended to members (excluding Government members) tons	3,000,000

Rapid progress is being made in the revision of the rules of the Exchange and in the reclassification of mines. That work is in the hands of the following committee:

J. R. Thomas, president, Carbon Fuel Co., Charleston, W. Va.; W. C. Ireland, sales manager, Jamison Coal and Coke Co., Pittsburgh, Penn.; Harry Boulton, president, Central Pennsylvania Coal Producers Association, Clearfield, Penn.; John J. Tierney, vice president and general sales manager, Crozer-Pocahontas Coal Co., Philadelphia, Penn.; John J. Brophy, treasurer and general manager, Piedmont and Georges Creek Coal Co., Frostburg, Md.; Arnold Gerstell, sales manager, Percy Heilner and Sons Co., Philadelphia, Penn.; W. A. Marshall, president, New York Wholesale Coal Trade Association, New York, N. Y.

EDITORIALS

The American Job and His Comforters

NO GREAT confidence in the future of business will come to the citizens of the United States by listening to the assurances of Secretary of Commerce W. C. Redfield, for that functionary has been vouchsafed many visions of a conflicting nature which he has been at no pains to reconcile. In fact, Mr. Redfield is a two-headed Janus. It has been noted for long that one head shouted "Trade with Europe" and another head cried as vigorously "Forbear."

He has indeed reached nearer than any other the Scriptural injunction, "Let not your right hand know what your left hand doeth." With one hand he would aid American trade to enter European markets regardless of any peculiar aptitude for such invasion; with another he would restrain that same trade in that identical purpose, and do it equally without regard to the fitness of things. He reincarnates for us that Launcelot Gobbo, whose uncertainty of view so greatly amuses the audience in a presentation of the "Merchant of Venice."

But in regard to domestic trade, his attitude is equally perplexing. " 'Buy only what you need, but buy it now,' seems good patriotism," he remarked when addressing the National Retail Dry Goods Association last February. By the way, this was not a well-selected audience for the delivery of such a message, for everybody, as far one can observe, is buying dry goods to the limit. Advice to purchase is not needed. The dry-goods trade needs only the vanity of the public, which never fails so long as the purse holds out.

The need is not for expenditures in trivialities, but for outlays in permanent possessions—houses, railroads, water-works, sewers and roads. Mr. Redfield stimulates these basal industries by such words as these: "It cannot be expected that prices will fall soon to their pre-war level." Surely this is cold comfort. Before the war the cost of a house might be $4500. To construct that same house today would cost $7000. After a few years, Mr. Redfield suggests, if he does not actually say it, a similar house may be constructed for $4500. The investor would lose $2500 on his expenditure and meanwhile, if he lets the house, he will get only an insignificant net rent and if he occupies it he will make little by being his own landlord, for while present-day rents may be considered high on the basis of cost of original construction and on the former costs of maintenance, they are not high on work now constructed especially when present costs of maintenance are also considered.

This is the "modest part" Mr. Redfield is demanding of the home builder and the investor in property. "It may mean," he adds, "a little sacrifice here and there in paying at this moment a *somewhat higher* price than we might pay *a month or two later*, but we have become accustomed to sacrifice for the country's sake." Mr. Redfield does not italicize "somewhat higher" and "a month or two later." The fact is, his vision should have stretched over a longer period. The word "sacrifice" would then have been well justified, for the price so regarded would be by no means only "somewhat higher."

But all this argument of Mr. Redfield's is not based on facts. The cost of living as a whole is to go up, not down, though edibles will probably fall somewhat. Above all, rents and the price of bricks and mortar are to rise and not fall. There is no risk at all in building. Construction can go ahead without any apprehension. It is not self-sacrificing to build, however patriotic it may be. It is a wise move, one dictated by prudence. The only doubt that arises in the mind finds a place there because of the attempted stabilization of prices by Government pressure.

The Government is forever alarming the public. Its action retards rather than accelerates business. Men wait for the Government price. If there is no reduction, they still wait; if there is one, they take courage to hope for more. No worth-while business was ever secured on a declining market. It is such a market Mr. Redfield is trying to secure for us, telling us all the time that it will come about very slowly. Yet he is doing all he can to hasten a fall in market prices.

No wonder the public halts despairingly. Every purchasing agent is afraid to buy lest Mr. Redfield should succeed in doing him an injury. Meanwhile that worthy pats him on the shoulder and says: "My friend, help the country by buying and I will try to hurt you by lowering the value of what you buy. Stimulate the country by your sacrifices while I scare it stiff by my actions and speeches."

Every engineering office should be furnished with a library of books containing data fundamental to the work of that department. The library should be supplied by the company and augmented as often as appears necessary. Why should the engineer be required to supply the mental aids to his work—the books—any more than the physical aids—the transits, levels and tapes? With such salaries as are paid, many men are obliged to let their work limp rather than buy the multiplicity of books necessary for complete and ready reference.

Resumption Is Already in Evidence

SINGLE-TRACK minds—and such cerebrations are in the majority—are always ready to assume that on no basis can any business structure be reared but that on which it has been reared in the past. There are engineers who, seeing an uncompleted tipple, breaker or washery, and not having the plan, would say: "Pull it down. I will design another." Certain minds seeing the present wage structure, and the attitude of labor and capital, have despaired of erecting on it anything of value and have called at once for tools of demolition. "Pull it down," was their cry, "and build a new structure on the original bed rock."

Reconstruction rather than resumption was all that would please them. Tories and radicals were equally

vocal in favor of reconstruction, each seeking a diametrically opposite end. To the tory a fall of the structure of the last few years, with dust, noise and destruction seemed better than resumption. But nevertheless the resumers are winning. We go forward from where we left off. The war structure is still a part of the building, as stable as anything that was there before and as solid as anything we may add thereto hereafter.

It is strange how many people fail to react immediately to a new order and try to persuade themselves into believing it is merely temporary. But the new order is developing a conservatism of its own. New wages and new prices have a permanency that cannot well be disturbed. A torn-up tree or other plant can seldom be replanted, and indeed few there be that want to try the experiment of disturbing such a well-developed organism.

The price of stocks have been steadily upward for the last two or three weeks. The output of coal is on the increase. Coal orders are already more numerous. The price is going up, especially the price of anthracite. The reports of all the authorities on trade which we publish weekly are now cheering. *Bradstreet*, the *Dry Goods Economist*, the *American Wool and Cotton Reporter*, *Dun* and the *Iron Age* all tell stories of resumption in all, or in their special, fields. We are growing warm toward business. What some of us have reasoned, millions of us are beginning to know. The tide has turned. In a month or two prices will be a trifle higher if anything, and yet no one will be talking about high prices for we shall realize that they have come to stay and that what we buy can be sold for more than was paid for it. When that is the case, prices are no longer high.

"A man in his time plays many parts." In the morning he dons his working clothes and goes into the mine and does service for others. Anon he leaves the mine and dresses to do his marketing, requiring others to do him service. What a marvel is in that dressing! Before it the miner is employee, after it employer; before it servant, after it master. Who shall deny the solidarity of labor and capital when the twain are one flesh and change from one to the other by the shedding of a coat?

Law of Permanence of High Prices

IN GENERAL the permanence of high prices amounts almost to the dignity of a law. There are exceptions, it is true. But speaking broadly high prices tend to remain, provided they last long enough to increase wages. The pocket which has been expanded almost never hangs with the old grace of outline. The reason is that wage rates tend to have permanence, the public mind having become receptive and favorable to the figures by which wages are denominated.

But this is not all. It appears that after a war at least some prices tend to increase rather than decrease. Wars that did little to stimulate some prices proved able to stimulate them immensely later, and some wars which raised prices greatly were followed by further price stimulation thereafter.

In what follows, the figures quoted are those of E. A. Kebler, published in the *Iron Age*. He shows No. 1 foundry pig iron sold in Philadelphia in October, 1862, at $18.61. In August, 1864, the same quotation on a gold basis was $29.44, the increase resulting from the Civil War. Lee surrendered in April, 1865. One would expect the price to fall with the ending of what, on the face, would appear to be the whole exciting cause, but the average price for the year 1866 was $46.67. The Franco-Prussian War, which was declared July 10, 1870, when No. 1 foundry at Philadelphia was selling at $32.75, ended May, 1871, with the same pig iron selling at $35.50. In June, 1872, the price had mounted to $53.37.

The Spanish-American War did little to stimulate the price of pig iron till its close. Valley bessemer, when the war really began—January, 1898—was $9.12. War was actually declared April, 1898, the price having risen to $9.66. When the war ended—August, 1898—the price was only $9.60, yet in December, 1900, it had reached $24.20. The Russo-Japanese war, lasting from Feb. 10, 1904, till Sept. 9, 1905, raised the price of Valley bessemer from $12.64 to $14.95. In May, 1907, the price had mounted to $23.28.

Thus the high prices that close a war and fill every one with alarm are followed by a flood that sweeps everything before it. There is even now a telltale white cap on the free surface of the gently receding waters which shows that the overwhelming wave of high prices, noticeable after all wars, is preparing to hurl itself landward.

Did you ever see an Italian, Slovak, Slav or Hungarian workingman wearing spectacles? Either the people of Italy, Checko-Slovakia, Jugo-Slavia or Hungary have exceptional vision or there are a large number of them stumbling along in semidarkness, unsafe not only because language makes them dumb, but because defects of vision make them blind. Faults, blamed to cerebration, which, if defective, cannot be cured, may really be due to astigmatism or to the unadjusted focal length of the crystalline lens. Such defects of this kind as are congenital are probably more likely to be found among workingmen than among superintendents and managers, for these physical defects militate against advancement in the social scale.

Coal Resources of Germany

A SHORT time ago there appeared in *Coal Age* a request from a Montana correspondent asking for any information that might be available in regard to the coal reserves of Germany. The inquiry caught the eye of George Otis Smith, director of the United States Geological Survey, and he at once appointed one of the geologists of the Survey, Eugene Stebinger, to the task of compiling the information asked, from the records of the department.

It should be stated here that the U. S. Geological Survey, under the guidance of its director, has recently been engaged in extending its service by compiling vast stores of information and data relating to the mineral resources of other countries, which are now available to those seeking such facts.

The contribution regarding the coal resources of Germany, prepared especially for *Coal Age*, by Mr. Stebinger, will be found on another page of this issue in the Discussion by Readers department. It is valuable as forecasting the future of the world's coal trade by the presentation of suggestive data.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Every prospect seems favorable to a strike of long duration soon after the Peace Conference comes to an end in Europe and the ratifications are received. It is questionable whether a strike is such an evil as some regard it. Nothing would do as much as a suspension of work to give tone to the market and make the hesitating and bargaining consumer turn in his orders early. Even the prospect of a big strike might bring the prosperity we are seeking. When purchasers begin to fear that their orders may not be filled unless placed early, they will deluge the markets with inquiries and the market place with unavailing outcries.

For the good of the United States and for the advantage of the whole world, the six-hour day must not be put in operation, certainly not suddenly. It is a revolutionary provision to say that we will do with only 75 per cent. of the prosperity we have been enjoying hitherto. It may be said that we have already cut the hours from 12 to 10 and from 10 to 8, but the reduction from 12 to 8 hours has been slow. It has been accompanied by the speeding-up process. It had its justification in the greater efficiency inherent in the short-time laborer. Few men *worked* 12 hours. Nature would not permit it. They stayed on the job 12 hours and did as little as they could.

A Six-Hour Man Will Earn a Six-Hour Living

On the other hand the eight-hour man can easily keep up his zest for every one of the eight hours. He could hardly be more enthusiastic if he worked only six, so there is no economical advantage securable in a six-hour day. It may, however, be justified by the thought that men need more leisure and could do with less goods, but if there is anywhere a man who desires less goods he is extremely hard to find; and it is well understood that the workman seeks more leisure without any countervailing reduction of his power to purchase.

Resistance to the desired shorter time is therefore a public duty of the operator which he will probably perform even if it involves a strike. He will be equally well justified in opposing the institution of Saturday as a holiday. As for increases in tonnage, daywork, yardage and deadwork, the operator could pay them and turn the charge over to the public, but the public is not disposed to pay any more for coal and might prove restive. A refusal to grant the mine worker what he wants is therefore more than likely.

If Time Is Short Coal Will Be Short Also

If we have a six-hour day and a five-day week, there is bound to be a shortage of coal. The bituminous mines have worked nearly every winter an eight-hour day and six-day week. They produced under that arrangement 60 per cent. more than they will under that proposed, and yet they barely filled the demand for that season. Formerly they got a large increase of force from across the seas month by month. A careful investigation by the National Coal Association shows that as soon as the war is over 36,000 foreign-born miners will go abroad and half of them will stay. The men going overseas constitute only 2.4 per cent. of all the present force. Those who will remain will constitute about 1.2 per cent. This does not seem much, but the flow should be the other way.

There is reason, therefore, to expect an extremely busy winter even if the mine workers work a full 48-hour week. With a 30-hour week the public is not likely to be satisfactorily or even safely supplied. As usual, the mine operators will be recommended by the public to give the 30-hour week, will be asked to concede the wage increase and then blamed when, as a result, cost rises and the demand for coal is not met.

The export activity of the United States in Sweden, Holland and Brazil is being used as a reason why Great Britain cannot afford to accede to the miner's request for a six-hour day and for largely increased wages. It is likely that the British miners will call on our miners to hobble the American coal trade with the same hampering restrictions they are able to impose on British trade. Output is hereafter to bear equal fetters the world over. That will handicap all nations equally and so will be fair. That is, it will be just as disastrous to the American workman as to the British. The real pay of both will be equally cut.

Slowness of Run To Affect All Equally

At a meeting of the officers and members of the grievance committees of the locals of eight mines of the Lehigh & Wilkes-Barre Coal Co. it was decided that all mine workers must stay away from the mines on "idle days." Each local will be asked to list such work as is regarded "necessary." At this meeting representatives declared that at some collieries the coal that was mined in two days was brought out in one day. Thus the day workers were getting only one day's pay for two days' product. To make this practice of thrifty miners unprofitable a fine of $15 or the calling of a strike was threatened.

The complaint is not so much against the company as against the men who work so steadily. The locals discussed calling on the company to break up the practice. The men are complaining that some men get nine or ten cars a day and others but one or two. They assert that the successful work of the men who thus make large wages is featured whenever increased wages are demanded. It is then shown that they have made large wages and it is argued that no increase should be given. This is the reason, say the grumblers, why meager increases are the rule. However, any one who has been around the mines knows that there are other, and extremely important, reasons for differences in output, these differences relating to the steadiness, energy and skill of the men. The best places are given to the most reliable workers. If there is a bad place it is apt to fall to the man whose work is so poor that the management wishes he would quit.

On Mar. 13 Local No. 506 passed a resolution vigorously condemning miners at the Locust Spring and Locust Gap collieries who cut coal on idle days and attached a fine of $25 for each offense. Similar resolutions providing fines have been passed by many locals in the Shamokin, Mt. Carmel and Mahanoy City districts. The locals are determined to put these resolutions into practice. The General Mine Committees of Shamokin and Mt. Carmel, which met at Kulpmont, fixed the fine, not at $25, but at $50.

What Else Could He Expect?

and until Old Man Economics changes his nature, it's about all the little fellow can expect!

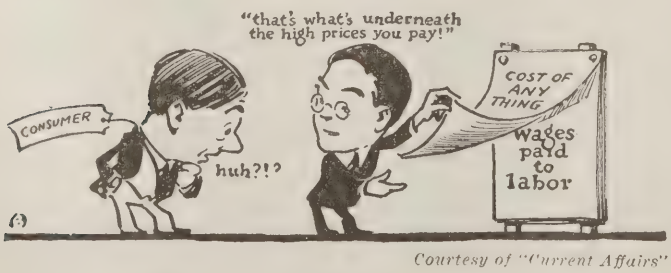
Mine Reverts to the Frick Scale

The mine workers of the W. J. Rainey Coke Co., in the Connellsville coke region, have been on strike during the past week because of a decision on the part of the company that it will no longer supply free explosives for the shooting of pick-mined coal.

The operators in the Connellsville region follow, in general, the "Frick scale," a scale made by the H. C. Frick Coke Co., which is usually posted by the other operators of the region around Uniontown and Connellsville immediately after the Frick company announces a change in wage. The Frick scale provides that free explosives shall be furnished for the shooting of machine-mined coal, but that what little explosive is needed by the pick miner shall be provided by himself.

During the war several of the Connellsville operators, seeking to hold their men, set aside this exception and supplied powder to all who needed it in their work. Now that the demand for coal is lessening and prices have shown a weakening, the practice has become a burden, and the companies are desirous of returning to the scale provision. When the Rainey company tried to get from under their revision of the scale the men struck.

It is reported that many of the men desire to continue at work, but have been detained from so doing by fear of violence on the part of the leaders of the strike. For this reason the State Police were called on for protection, and operations were resumed Mar. 27 with a partial force.



Resent Punishment of Intimidators

Trouble is brewing in Raleigh County, West Virginia, where on Mar. 19 thirteen members of District No. 29, of the United Mine Workers of America, were indicted by the Raleigh County Grand Jury charged with being parties to a shooting at the mines of the E. E. White Coal Co. that took place in November, 1917, placing the lives of several miners in jeopardy. Two felony indictments were returned against each man, one for attempted murder and one under what is known as the Red Man's Act. The men who are indicted will come up for trial at the June term of court. They are: Lawrence Dwyer, international board member; Obe Clendennin; Ed Snyder; Toney Stafford; George Lucas; Tom McGinnis; Dorr Snuffer, Tom Murphy, Ed Hornick, Will Owens, Tom Lethco, Tony Sarazzo and Karl Kram.

If the men are convicted on either count it will mean a sentence in the penitentiary. For that reason feeling runs high among the miners and some of the bolder ones are resorting to threats as to what will happen when and if the men are tried. At preliminary hearings there were manifestations of this spirit of resistance to the law.

Want Shorter Day but No Bolshevism

The convention of District 21, United Mine Workers of America, at Muskogee, Okla., adopted resolutions denouncing the Industrial Workers of the World and the Working Class Union and organizations preaching Bolshevism in the United States. The convention framed a policy to be recommended to the International Convention, the basic principle being a six-hour day, which, it was asserted, will keep the men at work and at the same time eliminate surplus production.

Great Britain's Miners Do Not Strike

The miners in Great Britain, except about 7000 in South Wales, seem to be willing to accept the ruling of the majority in the Sankey commission. That unimportant 7000 are already on strike. While, however, the miners are pacified there are others who now seek an increase. The railroad men want about a half billion dollars more pay per year, and the agricultural laborers are also seeking a larger remuneration. The cotton industry is also looking for increases in wage.

The scheme has been to carry this burden as taxation and make those pay it whose incomes have been halved or more than halved already by tax charges. Others who are asked to pay it are the brain workers whose incomes have not risen to accord with the general increase in the cost of living. "Make the frugal pay," is not a safe doctrine for any nation. Spending her savings, how will Great Britain ever be able to sustain her commercial undertakings on which the prosperity of her people depends?

However glum and uncertain the situation may be in Great Britain, congratulations cannot be withheld now that a strike of the miners seems unlikely, for no one, except the railroad men, have an equal power to make matters uncomfortable. If the strike which was to have been called on Mar. 22 (in case all the demands of the miners were not granted) had actually been called, the result would have been disastrous in some places within as few as three days, if press notices are to be credited.

But the miners' conference decided to use discretion. It did not favor an automatic strike, and on Mar. 26 it decided to recommend the acceptance of the Sankey report and provided for a ballot to be taken on the subject. The conference urged the men to continue at work on day-to-day contracts until the ballot could be taken.

It will be remembered that a general industrial conference was summoned by Premier Lloyd George last February. It proposed to consider the causes of labor unrest. It adjourned after a short session, leaving a committee to make the proposed investigations. That committee has come to certain conclusions and it will report on Apr. 4. The committee was a large one. There were 30 representatives of the employers and an equal number of representatives of the labor unions. The recommendations are said to be quite far-reaching and it is declared that they were unanimously adopted by the committee. Their publication is eagerly awaited by the public.

The British troubles have been quite extensively described in these columns because they affect the United States closely. Our labor matters are quite apt hereafter to be linked with those of Great Britain, for the workingmen realize that competing nations, like competing employers, can only continue to do business if compelled to pay like increases in wages and give comparable improvements in working conditions.

On Feb. 26 Robert Smillie, who is president of the Miners' Federation of Great Britain, made an appeal to the coal miners of the United States as follows:

"I note that it is already rumored that arrangements are being made to import coal from America in the event of a strike here. I think I may appeal with full confidence to my comrades, the mine workers in the United States, to refuse to assist the British capitalists who are trying to defeat our efforts to improve the standard of living of our mine workers over here."

Shorter Hours Demanded in Germany

The miners in the Essen region of west Germany adopted a resolution, Mar. 17, demanding a further reduction in the working day. They want a 7½-hr. day to begin in April, a 7-hr. day to begin in 1920 and a 6½-hr. day to be put in operation in 1921.

A prominent Socialist member of the National Assembly, named Sachse, tried to induce the men to remain satisfied with the 8-hr. day just recently introduced, but passionate protests and threats of an immediate strike broke in on his presentation of the needs of industry and of the public.

How a Mushroomed Cutter May Raise the Devil

Safety letter from Consolidation Coal Company to its Safety Committees

On November 9, an assistant foreman was cutting a bolt from the bottom of a mine car, when a piece of the cutter flew off and struck him in the eye. The eye was destroyed.

THE blows of the sledge on the top of a cutter gradually flatten out the head, mushrooming it down around the sides. At last, under a final blow of the sledge, a burr from this mushroomed head lets go and flies away like a bullet from a gun. Around steel works and machine shops where they use chisels and cutters frequently they have found out the danger of mushroomed heads on tools and they wage a continuous war against them. But around the mines — I'll leave it to you fellows, and if I lose, I'll buy the hat — there's not a single man who has worked in the mines for a year, who has not seen so many mushroomed cutters and chisels that he almost believes that that is the way they come from the factory.

Let us wake up on this point. Let us start a war against mushroomed chisels, cutters and other tools and not stop till every last one of them has been to the shop and had some first-aid work done on it by the blacksmith. I am told that the best way is to cut the burrs off the head cold and then dress it up on the emery wheel; but don't forget GOGGLES MUST BE WORN WHEN DOING A JOB LIKE THIS. Please don't let us lose an eye in doing a safety job. Let us make this job a safety job through and through, a job for safety and done safely. This is just a little side line in our regular Mine Safety work, but let us make a good clean job of it while we are at it, so that we can report next month that every tool from the blacksmith's to the trackman's has been made safe.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Traffic with Germany

Letter No. 2—I was much interested in reading the letter of S. D. Hainley, *Coal Age*, Jan. 30, p. 243. The question he raised, in regard to whether or not we should traffic with Germany, is a two-sided one and, before it can be answered, each side must be thoroughly and carefully considered. What Mr. Hainley has said in regard to our longing to see the Huns driven back to Berlin is true. It is also true, as he has stated, that "Germany is defeated but not conquered."

Far better would it have been for Germany and for the rest of the world if she had made peace the day the United States entered the war, but her pride kept her from doing this. It would have been better for her had the Kaiser remained at his post instead of fleeing his country, which is now suffering from the spread of Bolshevism and its industries undermined.

However, viewing the question from the standpoint of the future, we have everything to gain by assisting to put German industries again on their feet. Previous to the war, goods "made in Germany" found their way into every country. Many of these manufactures could not be duplicated elsewhere. The breaking out of the war and consequent stopping of importations to this country from Germany was a matter of great inconvenience and loss to many of our industries.

These concerns were obliged to remodel their factories and study to produce what they needed to carry on the industries in which they were engaged. Instances of such conditions are found in the lack of German dyes, chemicals and various fine instruments. Some of these have since been produced in this country at a considerable cost of study and labor that, in many respects, has been a benefit to our own industries.

The question of the future traffic with Germany is a broad one, and I hope to see it fully discussed.

Rawdon, Que., Canada. C. MCMANIMAN.

Coal Resources of Germany

[In response to the request of *Coal Age* for what information might be available regarding the coal reserves of Germany, including any recent discoveries and asking for a brief discussion of the present status and probable changes in the German coal trade as a result of the war, George Otis Smith, director of the United States Geological Survey, writes: "I take pleasure in sending you, herewith, a few notes on these questions, together with a short résumé of the coal situation in that country, prepared by Eugene Stebinger, a geologist of this Survey."—EDITOR.]

Letter No. 1—Referring to the inquiry regarding the coal resources of Germany and the prospective development of the coal industry in that country, which appeared in *Coal Age*, Jan. 9, p. 71, and to which my attention has recently been called, permit me to say that there have been no recent discoveries of coal, in Germany, important enough to change her status as to reserves, or at all comparable with the finds in Kent County, England; the Campine field, in Belgium; or the additions to the Dutch reserves made by the discoveries in Holland.

The northern limits of the Ruhr Basin, lying east of the Rhine, in Westphalia, which is by far the most important coal field of Germany today, have always been indefinite owing to the gradually increasing depth of the coal beds and the uncertainties of mining under the deep cover of the overlying barren formations, which are full of quicksands and troublesome water-bearing horizons.

The estimates of the reserves in Westphalia are, therefore, subject to considerable manipulation, but there has been no additional information gained that would tend to remove any of the uncertainties, in this field. It can, furthermore, be stated that any addition to the deep-lying and inaccessible reserves of a country where the total coal supply is large enough to last many hundreds of years, can have but little practical importance for the present generation.

GERMANY'S PRODUCTION AND CONSUMPTION OF COAL

Germany's recent position in the coal trade of the world can be briefly summarized as follows: In respect to reserves of unmined coal, she ranked the first in Europe, having a total tonnage of over 55 per cent. of all the coal on that continent, as compared with 25 per cent. for the British Isles. If the known or actual reserve figures, alone, be considered, thus confining attention to what might be termed "commercial reserves," rather than to the ultimate resources obtainable, Germany's proportion then drops to 38 per cent. of the total European tonnage, as compared with 54 per cent. for the British Isles. These reserves are almost entirely bituminous coal, an unusually large proportion being of a coking grade. The reserve of anthracite is insignificant.

In world production, Germany has ranked third, following Great Britain very closely. During the ten years previous to the war, however, her output had been increasing at over twice the rate for Great Britain; and if the war had not intervened would probably soon have exceeded the British production. Her coke output had risen to 32.2 million tons, or over one-half of that of all Europe and 50 per cent. greater than that of Great Britain, her nearest competitor.

In consumption of coal, Germany has ranked second in the world, following the United States, while in exports she also ranked second, following Great Britain, her total exports being about one-half of that of the latter country, of whose coal she was one of the largest importers. In consumption per capita, however, she ranked fourth, the amount being 2.12 tons per person, as compared with 4.82 tons for the United States.

GERMAN COAL DISTRICTS WEST OF THE RHINE

There are two coal districts lying west of the Rhine, in Germany, in the territory now occupied by the armies of the Allies and the United States. These are the Saar field and the left of Rhine fields. These two

fields produced only 11 per cent. of the total coal output of Germany, in 1913, and but 7 per cent. of the coke output. The Saar field, alone, produced nine-elevenths of this coal and nearly all of the coke. The total of the coal reserves of these two districts has been estimated as amounting to only 7 per cent. of the total reserves of Germany, prior to the war. The portion of the Saar Basin lying in Alsace-Lorraine is comparatively unimportant, having produced barely over 20 per cent. of the total production for the field in 1913.

Nearly all of the coal of Germany lying east of the Rhine and amounting to over 90 per cent. of the total reserve, is concentrated in two great fields: the Ruhr Basin of Westphalia lying just across the Rhine, and the Upper Silesian field in the extreme southeastern portion of Germany. The latter of these fields is largely inhabited by Polish-speaking peoples.

The Ruhr and Upper Silesian Coal Fields East of the Rhine

The Ruhr Basin contains over 52 per cent. of the total coal reserves of Germany and produced over 114 million tons, or over 60 per cent. of the total coal for the country, in 1913, and 83 per cent. of the total coke output. The latter was used in producing over two-thirds of the iron and steel output of Germany, besides forming the basis of her extensive chemical industry, in the manufacture of coal-tar derivatives. About 62 per cent. of the immense coal reserve of the Ruhr Basin is made up of coal that can be coked, under present practice.

The great value of the Ruhr coal field is much enhanced by excellent transportation facilities. Ocean-going vessels can ascend the Rhine to the west edge of the field, thus making the export facilities equal to those of the various British coal fields bordering on the sea. Strange to say, however, a strictly overseas export trade, comparable with the British foreign trade in coal, was never developed.

The Upper Silesian field, second in importance to the Ruhr Basin, was estimated to contain about 40 per cent. of the total German coal reserve. It yielded 23 per cent. of the total output of the country in 1913. The coke of this field, however, is relatively unimportant. The coking coals make up only about 10 per cent. of the total reserve, while the annual coke output is only about 7 per cent. of the national total.

Other Coal Deposits of Germany

An account of the coal industry of Germany would not be complete without mention of the lignite and brown coal mining and the utilization of these products, which in the years prior to the war were developing very rapidly. In 1913 over 87 million tons of lignite and brown coal were mined in Germany, amounting to more than double the lignite production from all other world sources, and exceeding 31 per cent. of the production of all classes of coal in Germany. About 30 per cent. of this output was manufactured into briquets.

The lignite is mostly extracted from open cuts and, in these, is worked almost entirely by machinery, the labor involved being comparatively unimportant. During the war this feature made it possible to actually increase the output of lignite, while the output of bituminous coal fell off nearly 30 per cent., owing to labor shortage.

Immediately prior to the war, German exports of coal had risen to about 40 million tons, annually, as compared with 70 million tons for Great Britain, and about 16 million tons for the United States, the only other important exporting nations. During the previous seven years, the total German exports had increased very rapidly, which was largely at the expense of the British coal trade. The total increment for that period was over 58 per cent., as compared with a 1 per cent. increase of British exports, during the same years.

These increases, at the expense of British trade, were made principally in Belgium, Holland and France. The German exports were distributed as follows: To Austria-Hungary, 30 per cent.; Holland, 18 per cent.; Belgium, 16 per cent.; France, 15 per cent.; Italy and Sweden (together), 9 per cent.; Switzerland, 7 per cent.; and Russia, 5 per cent. It is noteworthy that the distribution of German exports was almost entirely to immediate neighbors, the strictly overseas exports, so important in the British trade, being of very minor importance.

Possible changes, in the coal trade of Germany and resulting from the war, especially with reference to exports, are obviously very difficult to forecast at present and cannot receive serious attention, before her internal problems and the complicated political and economic problems confronting the Peace Conference have been settled.

Changes in the German coal trade, however, are not likely to be so far reaching as those in the trade in the bewildering array of manufactured articles that, heretofore, have been sent to every corner of the world; because, as was pointed out above, German coal was distributed almost entirely to her immediate neighbors, over one-half of her coal exports going to countries with whom she has not been at war.

Eugene Stebinger, Geologist,
Washington, D. C. U. S. Geological Survey.

Future of Mine Labor

Letter No. 1—The foreword that appeared in *Coal Age*, Feb. 6, entitled "Perpetuating the Thrift Habit" should be of deep interest to every reader, whether he is an employer or an employee, in the coal industry. The writer draws attention, incidentally, to the labor situation in this country at the present time and finds that the proportion of married home owners is but 4 per cent. and that of married renters 11 per cent. of the entire force employed in the coal industry. The foreword urges the necessity of coal companies developing thrift among their employees, which is a most timely suggestion.

A careful analysis of the present working conditions in coal mining inclines one to the belief that the mine worker has but a poor chance to save. It is more probable that he will be obliged to draw on his savings that he has already laid by for the future. Should affairs in the coal industry take a downward trend, it is more than likely that a majority of coal miners will be compelled to dispose of their Liberty Bonds, in order to pay their store bills. This is particularly true of American miners who have their families to support.

In addition to the severe conditions brought about by the war, the spread of the influenza epidemic has thrown a heavy burden on the miner. Almost every coal miner, here, has been more or less knocked out by the "flu" and been compelled to take a lengthy

vacation, while confined to his bed or unable to leave the house and go to work. But, in the meantime, the bills have been growing; food must be bought and rent paid. The result is that anxiety and unrest have grown apace among the miners, who realize that they are not making a living.

Someone will ask what the miner did with his $150 that he formerly made in two weeks' time. Let me attempt to answer this question, at least in part, by citing a single instance that came under my observation not long ago. The facts are as follows: There worked, in one of the mines at this place, a Croatian by birth, whose name was John Seminovich. John was a champion coal loader. Last summer his output was over 445 net tons, which, at 59.85c. per ton, brought him over $266.

It may be said that this man ought to have saved $100 each month. He was stricken, however, with the epidemic that visited the town, being one of its first victims. For two months, the man was confined to his home unable to work. When he did recover and started to work in the mines, some foolish friend advised him to drink plenty of whiskey. Acting on this advice, John took more than was necessary and was unable to go to work again for a few days, which drew still further on his small savings.

This instance is but one of a hundred similar cases; and let me ask, Can it be wondered that many of our miners are, today, selling their bonds to meet their bills? I was told that some miners, in a neighboring town, sold $50 bonds for $30, being anxious to take anything they could get. One miner told me that he was not fool enough to let another man make money on his bond; but if he was unable to sell it before the ship sailed for his homeland, he would stick the bond in the fire and let Uncle Sam have the money, as he could not wait twenty years for his payment.

Importance of Maintaining Immigration

A short time ago there was an interesting discussion, in *Coal Age*, on the "Americanization of Foreigners." Some may think it an easy task; but one who is better informed and more familiar with the situation as it exists today will form his opinion only after a close study of facts and figures. The immigration statistics show that from 1900 to 1910, the influx of foreigners to this country was 13,515,886, which was a half-million more than the whole population of the United States in the year 1830. From 1914 to 1918, there was a loss in immigration amounting to 2,800,000, based on an average for the preceding eleven years.

In addition to this showing on immigration, the announcement is now made at Washington that practically 100,000 of our men have perished in camps, overseas and in transportation. Another 100,000 of our French and Italian workmen have left and returned to their native land, the State Department having received applications for that number of passports for this class of people, who were anxious to seek new opportunities abroad. In the face of these facts, our American Congress now wants to shut off immigration from European countries for four years to come.

May I ask, here, what kind of labor supply will be available to the coal industry in this country if immigration is to be stopped for a time? It is a well-known fact that the American miner has become restive under existing conditions. Being without steady employment in the mines, many have sought other occupations and entered other industries, while a number have left the country seeking more favorable conditions.

It is my belief that we are face to face with one of the greatest labor problems in history. There will be an increasing demand for coal and a lack of labor to produce it. With this prospect in view, there will be few coal miners, indeed, who will be able to purchase the Fifth Liberty Bonds, unless there is a change in the working conditions at the mines. Our coal operators need to come into a closer relationship to organized labor. There is the need of sane and sound coöperation on the part of both operators and mine workers.

Waterman, Penn. JOHN MAJER.

Barometer vs. Outflow of Gas

Letter No. 1—The suggestion regarding the utilizing of mine gas, by burning it in the power-plant furnaces, and the resulting dangers to which attention has been drawn by W. D. Owens, who discussed the feasibility of the plan, *Coal Age*, Feb. 20, p. 372, raises the question of the effect of barometric changes on the outflow of gas in mines.

It is the contention of many able mining men that the gases found in mines are more sensitive to atmospheric changes than the barometer, which we understand is designed to indicate any change in atmospheric pressure as it occurs. It is claimed that, owing to the great sensitiveness of the gases accumulated in the mine workings and abandoned places, there is liable to take place a dangerous increase in the outflow of gas from these places, into the mine airways, before any reduction of pressure is indicated by the barometer.

Personally, I fail to see why a barometer when properly constructed should not adjust itself simultaneously with any change in the atmospheric pressure when that takes place. The fact that barometers are used as altitude indicators and will readily show a difference as low as five feet, with accuracy, is proof, to my mind, that they are very sensitive to the slightest change in the pressure of the air.

However, I would like to see an expression of opinion by other readers of *Coal Age*, as this is an important point in considering the possible dangers that may arise in connection with the proposed scheme of utilizing mine gas in the manner described. Mining men have been led to rely on the indications of the barometer and if I am not mistaken, it has been stated that these indications commonly precede the effect of atmospheric changes in the mine. E. P. BRENNAN.

Thomas, W. Va.

Panel System of Mining

Letter No. 1—Referring to the inquiry of R. J. Pickett, *Coal Age*, Feb. 27, p. 419, in which he proposes a change in the panel system that is already in use in his mine, permit me to say that his proposed plan does not strike me favorably for several reasons.

In the first place, the concentration of the haulage system, in the old plan where rooms are driven to the right and left of each pair of butt entries, in my opinion, should more than equalize or counterbalance the back haul that he mentions, and which is necessary in the rooms driven toward the main heading.

Mr. Pickett's proposal is to drive one heading and an 18-ft. air-course, in place of the two butt headings of

the present plan, and turn rooms off of the entry only. His argument is that it will then be necessary to drive the cross-headings only 258 ft., instead of 442 ft., before he can turn another pair of butts and open rooms on those entries.

However, he must remember that, for the same tonnage, the time of development is rather in favor of the old plan, which gives twice the number of rooms for less than double the distance driven on the cross-entries. Again, there is a little more narrow work in his proposed plan, because he must drive 2 × 258, or 516 ft. of crossheadings, besides the necessary crosscuts in the new plan, as compared with 442 ft. of cross-entries and crosscuts in the old plan, in order to open practically the same number of rooms.

There are, moreover, certain disadvantages in the proposed plan. For example, an 18-ft. air-course 1000 ft. long will be difficult to maintain and will require much timbering. Again, the work of drawing pillars will be in progress, at the faces of the rooms in a preceding panel, only 10 ft. away from the rib of the 18-ft. air-course. The falls in the pillar workings would be liable to break over the pillar separating the air-course from the faces of the old rooms.

Finally, the ventilation will be more broken up, in the new plan, and more difficult to maintain than by the old system. In case there is a grade requiring the installation of a room hoist, the system would be less efficient where the rooms are driven off a single entry only, than where rooms are driven to the right and left of both entries. J. B. B.

Colorado Springs, Colo.

Letter No. 2—After a little study of the proposed change in his present plan of mining, described in the letter of R. J. Pickett, *Coal Age*, Feb. 27, p. 419, I must say that the proposition does not appeal to me as having any advantage that would warrant making the change suggested.

Mr. Pickett has not given many essential facts that bear on the question of mining coal, such as the direction and amount of dip of the seam; depth of cover; condition with respect to gas; and, finally, the reason why the panel system was adopted in working this seam, whether owing to the presence of gas or the liability to gob fires. In the absence of these data, it is only necessary to discuss the relative advantages and disadvantages of the old and new plan of working.

The disadvantages of the present method, as given by Mr. Pickett, are the back haul required in rooms driven toward the main headings; loss of much coal owing to bad roof conditions; poor ventilation and difficulty of maintaining good roads, owing to the drainage being poor in the rooms; and, lastly, the slow development of the mine under the present system.

Judging from the fact that the drainage in the rooms is poor, it may be assumed that these are driven practically on the strike of the seam. But this feature would still be true in the method that he has suggested as a means to avoid the back haul mentioned. There is, therefore, no advantage to be gained in respect to this item.

Again, I fail to see that the roof condition would be improved by the new plan of working. On the other hand, the driving of an 18-ft. air-course would argue against the plan. My advice is that, if the roof is bad, owing to the action of gas in the strata, or other conditions, he should study to overcome these difficulties by proper measures. A frail roof may require larger pillars and less width of opening. Excessive roof pressure, due to depth of cover, must be relieved by inducing falls in abandoned rooms and other waste places. No timber should be left standing in the gob. Avoid caving rooms when it would menace roads or air-courses.

In respect to ventilation, the new plan would require two splits of the air to ventilate the same number of rooms, where a single split only is required in the present system. Also, the ventilation of the mine would be more expensive, owing to the necessary construction of air bridges and extra stoppings, or because of an increased mine resistance if two panels are ventilated by a single current.

Speaking of loss of coal, it is important to observe that, in the new plan, there would be a larger percentage of coal in entry pillars, which I fear would increase this loss when working under the proposed change. While it is true that the plan may appear to offer a slight advantage at the start, because of the necessity of driving a shorter distance on the panel entries, before turning another pair of butts, this advantage would only be temporary, since the old plan provides the driving of two rooms for each room now turned.

In fact, in the end, the driving of the same number of rooms would be delayed by the time required to drive the 75 or 80 ft. extra on the panel entries, while the driving of an 18-ft. air-course would prove an awkward drawback to the progress of the butt headings. My conclusion is that the development of the mine, in general, would be retarded by adopting the plan proposed.

The question of the extra expense of back haul in rooms going toward the main heading must be contrasted with the greater outlay, in the proposed plan, for extra yardage, including the driving of crosscuts, labor and material for building extra stoppings, and the laying of two extra switches for the same room development, besides building extra partings or side tracks.

In conclusion, let me say that I would favor making no change, but improving the present plan of working, by adopting such measures as may be required to overcome the difficulties mentioned. My claim is that there is a greater advantage in the concentration of the work, in the old system, than would be possible if this change was to be made.

While it is true that concentration of work must not be carried to excess, it is likewise true that the hauling of coal from several partings widely separated may result in loss of time waiting for coal and require an increased length of haul in the end. W. H. LUXTON.

Linton, Ind.

Reducing Ventilation at Firing Time

Letter No. 6—Kindly permit me to say a few things concerning the question of reducing the ventilation in a mine, at firing time, to which reference has already been made by a few writers. An experience of 35 years as miner, fireboss and mine foreman leads me to believe that the practice of naming a particular time for the firing of shots is an extremely dangerous one.

My knowledge of ventilation, as far as gas and dust are concerned, has been gained while performing the duties of fireboss and mine foreman in some of the most dangerous mines in West Virginia. But it has

been my good fortune to have performed the duties of these two positions without the occurrence of a single accident.

Let me say then that, in a mine generating gas, the necessary thing to do is to employ a system of ventilation that will keep all working places, travelingways and haulage roads free from accumulations of gas and dust. In order to accomplish this, a sufficient amount of air must be kept in circulation and made to sweep not only the working faces but all void and abandoned places throughout the mine. By this means alone, can the mine be rendered safe and sanitary.

In my opinion, there never was any excuse for establishing a particular time for shooting, except where the ventilation of the workings is insufficient to keep them clear of the smoke and gases produced by the firing of occasional shots, from time to time. But such conditions only make the mine more dangerous and must be avoided.

Let me attempt to make my meaning more clear by supposing that we are operating a mine where 50 men are employed in blasting and loading coal, and the practice, in that mine, is to fire all shots at 12 o'clock noon. Is it hard to imagine what a dangerous condition must result from the smoke and gases liberated by the firing of, say 100 shots within a short period of time? No one can deny this danger, even if permissible powder is used, and the result would be much worse if black powder is employed. There would result, then, a condition of the mine air that would invite an explosion, and this would be greatly increased if firedamp was present in the mine.

Advises Having No Set Time for Firing

My custom has always been to have no set time for firing. Our practice is that a man is free to fire a shot at any time of the day when he is ready and is in need of coal. In this system, shots are fired, from time to time, throughout the mine. This gives the air current the advantage, because the smoke and gases produced by each blast are carried away as quickly as they are produced, and there is no large volume of smoke and gas contaminating the air. I am alluding here to mines where open lights are in use.

In mines where safety lamps are used, only permissible powders should be employed in blasting and no shot must be fired until the place has been carefully examined for gas and found to be safe. Every hole must be examined before it is charged and no shot permitted to be fired on the solid.

From my viewpoint there is much less danger, however, where gas is present, than exists in the presence of much dust. The gas is easier to handle and less destructive should an explosion occur. I believe that most everyone will agree with me that dust explosions seldom, if ever, occur in the summer time, while gas explosions occur throughout the year. The question arises, Can we create summer conditions in the winter time, in coal mines? This is a question worthy of careful consideration.

Allow me to pause here long enough to emphasize the fact that I am not in sympathy with the management of mines where explosions occur owing to the accumulation of gas in the workings. Such conditions can only result from the wilful neglect of duty, on the part of the mine officials in charge. The duty of every fireboss and foreman is to see to it that the mine in their charge is free from gas and ventilated in a manner that there is no danger of such accumulations taking place.

Dust must be kept down and not permitted to accumulate at the working face or on the roadways. This, however, is more difficult to accomplish in winter than in summer because the dry air circulating throughout the mine in the winter time dries out the workings, rendering them dutsy, in many portions where it is impossible to maintain a sprinkling system. The best thing to thoroughly saturate the dust in a mine, to my knowledge, is exhaust steam and this should be used until the desired effect is produced.

Morgantown, W. Va. ARTHUR STURM.

Letter No. 7—I have read carefully and with much interest the opinions expressed by different writers, as derived from their practice, in regard to reducing the ventilation in a mine at the time of shotfiring. I also followed the discussion of this question that appeared in *Coal Age* some time ago, but the result has not been to change my opinion in this regard.

Where the ventilation of a mine is by means of an exhaust fan, I can understand that there may be some reason for the suggestion of reducing the quantity of air in circulation, when firing shots. In that case, the mine is ventilated under a pressure below that of the atmosphere and the effect of reducing the ventilation would be to increase the mine pressure slightly.

Now, assuming that there is a considerable volume of gas accumulated in the old rooms and abandoned places, a slight increase of the mine pressure, due to the slowing down of the fan, would have a tendency to drive back the gases into the places where they are accumulated, and there would be less danger of their coming in contact with the work of blasting.

Observes Barometer and Water Gage

It has been my duty to oversee the firing of shots in a very gassy mine where gas was accumulated in abandoned places and much gas was also bleeding from the coal and freshly exposed strata. In the performance of my duties, having secured my lamp at the lamp cabin, I would proceed to read and make note of both the barometer and the water gage.

It was always my custom to observe whether the barometer was rising or falling. If the water gage was somewhat below the normal, which was generally caused by a low steam pressure, I would send word to the boiler room and have the fireman get up more steam, so as to increase the speed of the fan.

On going down into the mine and looking over the firebosses' reports, I would be able to judge, from those reports and from the information previously obtained, whether or not it was safe for them to proceed to fire the shots. On the other hand, if the shotfirers reported poor ventilation in the mine, owing to a reduced circulation of air, I would consider such a condition as unfavorable for shotfiring.

The result of many years' study and practice in mine gases and ventilation has been to convince me that better ventilation is needed at the time of firing shots more than at any other time. Owing to the expense of ventilating mines, it is a common custom among mining men not to produce a greater circulation of air than is necessary to accomplish the desired result. It is poor economy, however, to reduce the circulation and take a chance on the safety of a mine.

Linton, Ind. SHOT INSPECTOR.

INQUIRIES OF GENERAL INTEREST

EDITED BY JAMES T. BEARD

Enlarging an Airway

Kindly explain what increase in circulation should take place in the following instance: An airway, 3 x 3 ft. in section, is 1050 ft. long. At present, this airway is passing 2000 cu.ft. of air per minute, which is not sufficient for the proper ventilation of the mine, and it is desired to enlarge the airway so that its cross-section will be 6 x 6 feet.

The work was started at each end and continued until there remained but 50 ft. of the original 3 x 3-ft. airway. Assuming the power on the air remains unchanged, how much will the circulation be increased, at this stage of the work? STUDENT.

Denbo, Penn.

As described, the airway is now divided into three sections, the two end sections being each 6 x 6 ft., 500 ft. long, and the middle section 3 x 3 ft., 50 ft. long. First, write the formula expressing the quantity of air circulated by a given power, which is,

$$u = \frac{ksQ^3}{a^3} = k\left(\frac{Q}{X}\right)^3$$

In this formula, the potential factor (X) is evidently the ratio of the sectional area (a) to the cube root of the rubbing surface (s); and it appears that, for any given power on the air, the quantity in circulation varies direct as this potential factor.

In this case, it is necessary to find the value of the reciprocal of the cube of the potential factor X, for each section of the airway, which is expressed thus:

$$\frac{1}{X^3} = \frac{s}{a^3}$$

The rubbing surface of the original airway is 1050 $(4 \times 3) = 12{,}600$ sq.ft. The two end sections of this enlarged airway being alike, their potentials can be combined as that of a single airway having a rubbing surface $s = 2 \times 500(4 \times 6) = 24{,}000$ sq.ft., and a sectional area $6 \times 6 = 36$ sq.ft. The rubbing surface of the middle section is $50(4 \times 3) = 600$ sq.ft., and the sectional area $3 \times 3 = 9$ sq.ft. The corresponding potential values of these sections are, therefore,

Original airway, $\dfrac{1}{X^3_0} = \dfrac{12{,}600}{9^3} = 17.284$

Two end sections, $\dfrac{1}{X^3_1} = \dfrac{24{,}000}{36^3} = 0.514$

Middle sections, $\dfrac{1}{X^3_2} = \dfrac{600}{9^3} = 0.823$

$= 1.337$

Now, since the power producing the circulation in each case is the same, we can write

$$Q^3_0\left(\frac{1}{X^3_0}\right) = Q_x{}^3\left(\frac{1}{X^3_1} + \frac{1}{X^3_2}\right)$$

Finally, substituting the potential values in this formula and solving with respect to Q_x, we find, for the increased circulation in the enlarged airway,

$$Q_x = 2000\sqrt[3]{\frac{17.284}{1.337}} = \text{say, } 4700 \textit{ cu.ft. per min.}$$

We recall that this problem was answered, some years ago, in *Coal Age*, by request of a correspondent.

Prime Producer in a Coal Mine

The question is frequently asked, Who is the prime producer in a coal mine? I have listened to so many discussions of this question when the contestants did not seem to get anywhere that I decided, at last, to send it in to *Coal Age*, hoping that something worth while would develop.

My understanding is that the words "prime producer" are intended to refer to the actual producer in the operation of a coal mine. Taking the industry as a whole, is he the loader, the cutter, the driver, dayman, fireboss, foreman, superintendent, manager or operator? In other words, passing down the entire line of operatives, who can be singled out as the main spoke in the wheel?

If I may be permitted to express an opinion, it is that the actual producer is the loader who sends out his eight to twelve cars of coal each shift. But there is plenty of room for discussion here and I shall be glad to see the question argued to a finish. J. W. H.

Grant Town, W. Va

In the view of many, this is a story without an end; and it is not strange that a discussion of this nature often proves inconclusive. The operation of extracting coal from the earth and putting it on the market consists of a round of duties and performances that are interdependent. The question of which is the most important is like asking, Which spoke of a wheel performs the greater service? It is true the wheel may lose one or more of its spokes and still serve to carry the load, by increasing the burden on the remaining spokes. In the same manner, one or more of the operatives in a coal concern can be away from his post and the work still goes on.

Particular emphasis, however, may be placed on the word "producer," which means, in reference to a person, one who produces. To *produce* is to bring forth, the root meaning being *to lead out*. In that sense, the word has particular reference to the creation of value. The farmer *produces* crops by tilling the land; the miner *produces* coal by digging it from the earth. The musician *produces* harmony with his instrument.

In each several case, there is something created that is of value and which, but for the performer, would have no value. In this derivative sense, the man who digs the coal from the bowels of the earth is the real producer; because, by his labor, he has changed the potential value of the coal to an actual value that pays him for his labor. In other words, he has created value.

It will be remarked, doubtless, that the coal in place has a market value and can be sold and bought, which is true. But such value is purely speculative, until labor has made the coal of use in the world. *Coal Age* will be glad to have other views on this question.

EXAMINATION QUESTIONS

EDITED BY JAMES T. BEARD

Mine Examiners' Examination, Springfield, Ill., Dec. 17, 1918

(*Selected Questions*)

Ques.—It was found that smoke traveled in an airway 6 ft. high and 10 ft. wide, at the rate of 336 ft. per min.; what quantity of air is passing in a minute?

Ans.—The sectional area of this airway is $6 \times 10 = 60$ sq.ft. Then, assuming that the distance the smoke travels in a minute is the average velocity of the air, the quantity of air in circulation is $60 \times 336 = 20{,}160$ cu.ft. per minute.

Ques.—In a mine we are producing 40,000 cu.ft. of air per minute with 20 hp.; how many horsepower will it take to produce 50,000 cu.ft. of air per minute?

Ans.—For the same conditions in the mine airways, the power required to produce the circulation varies as the cube of the quantity of air produced; in other words, the power ratio is equal to the cube of the quantity ratio. Hence, calling the required horsepower, in this case, x, we have

$$\frac{x}{20} = \left(\frac{50{,}000}{40{,}000}\right)^3 = \left(\frac{5}{4}\right)^3 = \frac{125}{64}$$

$$x = \frac{20 \times 125}{64} = 39+ \textit{hp.}$$

Ques.—How does the change of atmospheric pressure affect a gaseous mine?

Ans.—Any *decrease* in atmospheric pressure is accompanied at once by an expansion of the air and gases confined in the abandoned workings and other void places in the mine. The action is contrary to what would take place under an *increase* of atmospheric pressure, which would compress the air and gases. A decrease of atmospheric pressure is indicated by a fall of the barometer, which is a warning of possible increase in the gaseous condition of the mine airways, which every mine foreman and fireboss should heed.

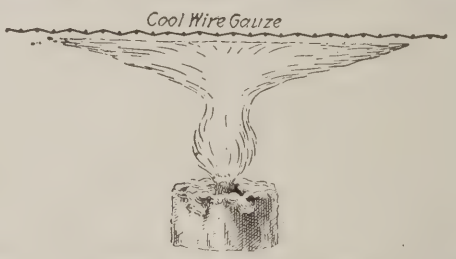
Ques.—What are carbon monoxide and carbon dioxide? Give their chemical symbols.

Ans.—Carbon monoxide (CO) is an extremely piosonous gas, the molecule of this gas consisting of one atom of carbon combined with one atom or oxygen. The gas is formed by the oxidation of carbon in the presence of a limited supply of air.

Carbon dioxide, while not being poisonous in the same sense as carbon monoxide, still produces a toxic effect on the human system. The molecule of carbon dioxide consists of one atom of carbon combined with two atoms of oxygen. This gas is produced by the complete combustion of carbon or carbonaceous matter in the presence of a plentiful supply of air. Carbon dioxide is always present to a greater or less extent in the blackdamp found in mines. The gas will not support life or combustion and is not, like carbon monoxide, inflammable.

Ques.—If a water gage placed in a door 4 ft. 6 in. high and 5 ft. wide shows a reading of 2.7 in. what is the total pressure on the door?

Ans.—Since 1 in. of water gage corresponds to a pressure of 5.2 lb. per sq.ft., a 2.7-in. water gage indicates a pressure of $2.7 \times 5.2 = 14.04$ lb. per sq.ft. The area of a door $4\frac{1}{2}$ ft. high and 5 ft. wide is $4\frac{1}{2} \times 5 = 22.5$ sq.ft. The total pressure on this door is, therefore, $22.5 \times 14.04 = 315.9$ lb.



Ques.—If 20,000 cu.ft. of air and gas, at its most explosive point, is passing through the mine, what is the quantity of gas given off, and what quantity of air should be added to render it nonexplosive?

Ans.—Assuming the question refers to a mixture of pure methane and air at its most explosive point, the percentage of gas in this current is 9.46 per cent. The quantity of gas given off in this mine is, therefore, $20{,}000 \times 0.0946 = 1892$ cu.ft. per min.

Assuming that the lower explosive limit of methane and air is reached when the proportion of gas to air is 1:13; or, in other words, the gas forms 1/14 of the entire mixture, the total quantity of air and gas, in this case, when the mixture has reached the lower explosive limit, is $14 \times 1892 = 26{,}488$ cu.ft. per min. On this basis, the quantity of air required to be added to render this air nonexplosive is $26{,}488 - 20{,}000 = 6488$ cu.ft. of air per minute.

Ques.—Explain the principle discovered by Davy and embodied in the safety lamp. What is the standard size wire gauze used in the Davy lamp?

Ans.—Sir Humphrey Davy (1815) discovered the important fact that when a wire gauze mesh, containing a certain number of a given size of wires to the inch, was depressed on a lamp flame the flame spread out

SHOWING EFFECT OF WIRE GAUZE ON FLAME

beneath the gauze, as shown in the accompanying figure. It was only when the gauze became heated that the flame passed through its mesh to the other side. This peculiar effect is explained by the fact that the burning air and gas, in attempting to pass through the mesh of the gauze, is broken up into a number of tiny streamlets, which are cooled below the point of ignition of the gas when coming into close proximity to the cool wire of the gauze. The flame is thus extinguished while the air and gas pass through the mesh. The wires cool the flame and prevent it from passing through the gauze.

By experimenting with different sized wires, Davy found that the best results were obtained by the use of a steel wire No. 28 B.w.g., made into a mesh of 28 wires to the inch. This was adopted as the standard wire gauze for safety lamps, and is still in use in England and this country. The gauze mesh has 784 openings to the square inch.

Book Reviews

Economic Production, Transmission and Use of Compressed Air

COMPRESSED AIR PLANT. The Production, Transmission and Use of Compressed Air with Special Reference to Mine Service. By Robert Peale, mining engineer and professor of mining, School of Mines, Columbia University. Third Edition. Pp. xx + 466 + 19 index; 5¾ x 9¼ in.; 246 illustrations. John Wiley and Sons, Inc., 432 Fourth Avenue, New York City, publishers. Cloth boards. Price $4.25.

This volume, prepared as it is by Robert Peale, needs no recommendation. It is preëminently a practical volume and full of illustrations that really illustrate. When a book of 466 "working" pages contains 246 illustrations, the reader needs some such assurance. We give it most cordially. The pictures are not put in because Mr. Peale had them on hand, nor because Professor Peale sought to ingratiate himself with others by using them, but because they are needed and explain the text. Let us qualify that last statement. Some of the illustrations are in themselves the text.

Professor Peale does not waste time explaining the obvious, like some writers who refuse to leave the readers any other labor than that of fathoming their utterly incoherent English. Two pages give all the history and reminiscences. The "Structure and Operation of Compressors" fills 40 pages. The mathematics of compression follow in the next 26 pages. Mr. Peale shows a remarkable restraint for a college professor. What is more, this is all the mathematics in the book.

The author abruptly leaves the subject for "Wet Compressors" and "Dry Compressors," and for "Compound or Stage Compression." Then follows the important subject of valves, self-acting air-inlet valves, discharge and delivery valves and those valves that are mechanically controlled. Performances of air compressors follow and then the accessories are discussed—air receivers, steam and pressure regulators. Then follows a chapter on "Air Compression at Altitudes Above Sea Level" and one on "Explosions in Compressors and Receivers."

The author advocates oil of extremely high flash-point. One recent authority believes that in an excess of refinement an oil of too high a flash-point is often used. He is of opinion that such an oil is apt to carbonize and fill ports, valves, discharge lines and the receiver. Still there is no doubt that the flash-point should be higher than any temperature the compressed-air cylinder is liable to reach with such attention as is given it, and probably Professor Poole would be satisfied to indorse a ruling on flash-point couched in such terms as these.

"Air Compression by Falling Water" finishes Part I, the second part having to do, not with the production of compressed air, but with its transmission and use. The book divides itself about equally between the manufacture and the use of compressed air. The first chapter in Part II is on the "Conveyance of Compressed Air in Pipes." Then follows "Compressed Air Engines," including hoists, and, a most important subject, "Freezing of Moisture."

The author cites the use at the Butte copper mines of several discarded return tubular boilers as receivers, the purpose being not so much to provide storage as to cool and deposit the moisture in the compressed air by the large surface exposed, thus preventing the freezing of moisture when the air is expanded in use. He suggests that boilers sunk in water would in warm weather and in warm climates give similar satisfactory results. Ten pages are given to the reheating of compressed air. All kinds of compressed-air mining machinery are then described — reciprocating drills, hammer drills, coal-cutting machines (29 pages), channeling machines, mine pumps, air-lift pumps and locomotives.

Oxyacetylene Blowpipe Repairs Machinery Permanently and on the Spot

OXWELDING AND CUTTING, Manual of Instruction. Pp. 124 + 2 index; 5 x 8 in., illustrated. Oxweld Acetylene Co., 646 Frelinghuysen Ave., Newark, N. J., publishers. Paper boards.

This is a really adequate, practical and simple description of the art of oxyacetylene welding. It is not in popular form, but neither is it abstruse. Its language is simple and its presentation convincing. The veriest novice can understand it. So great is its clarity that one cannot conceive that a really technical man wrote it. It seems more likely that it was written by some one who did not know the art of welding as well as he did the art of writing, but who was so hedged about by competent welders that his task was made easy and his information accurate and abundant.

The work of welding takes some judgment and skill. It does not merely consist of joining pieces of metal with the molten material of the filling rod. There is much more in autogenous welding than in mere soldering, for the temperatures are so high that expansion, contraction and conduction all have their influences. There is often a risk of the contraction causing a break. In butt welding plates judgment must always be used in laying the edges of metal which are to be joined together at such an angle that on welding they will by reason of the warping which results from the heat attain a certain lay with regard to each other by the time the blowpipe reaches any given point. There are also difficulties from the oxidizing of the metal and from the absorption of gases. The edges should be so beveled, grooved or otherwise disposed as to favor a satisfactory weld. The speed of welding is also a contributory factor. In butt-welding plates, when the edges of the plates tend to come together too fast and to crowd and overlap, the welding should be speeded up to overcome that difficulty.

The little volume starts out with a glossary of such words as are used in the book and not described in the text. A few notes on autogenous welding in general are followed by a short history of the oxyacetylene process. Acetylene was discovered in 1836, but no one produced it by methods adapted to commercial needs till 1891 and 1892, when Wilson in America and Moissan in France found means to make it at reasonable cost. It was not until 1901 that it was used with oxygen for metallic welding. In 1903 oxyacetylene welding was first used industrially, but until 1907 little was done to advance the method because oxygen was not a real industrial product. In 1907 the first liquid-air oxygen plant was placed in operation and from that time onward oxyacetylene welding was assured of success.

After detailing the work for which the oxyacetylene blowpipe is suitable, the author enters into the properties of metals from which trouble arises or assistance comes—the melting points, expansion and contraction, conductivity, oxidation, absorption of gases, vaporization and separation of elements. The methods and advantages of preheating and the provisions against expansion and contraction are then treated. Preparation of the material to be welded, the character of the flame (whether reducing or neutral or oxidizing) and the manipulation of the blowpipe follow. There are sections on aftertreatment and the causes of poor welds, and notes on the work with steel, cast iron, malleable iron, aluminum and copper.

Steel cutting is dispatched in short order, as is also the matter of acetylene generators. Thereafter the book becomes even more practical. The blowpipe is described and its manner of operation, and solutions are given of 60 practical problems with corrollaries, these covering both welding and cutting.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

German Coal in Alsace-Lorraine

Alsace depends for its coal supply mainly upon the Ruhr and Saar coal fields, and to a secondary extent on Belgium and England. The relative part played by the various coal fields has varied considerably from year to year. Up to 1910 the Saar occupied first place, but has been passed by the Ruhr, says Circular No. 5399, Comitè Central des Houillières de France.

The total imports of coal immediately before the war amounted in round figures to 2,500,000 tons per annum, of which 1,300,000 tons came from the Ruhr district, 1,000,000 tons from the Saar, 170,000 tons from Belgium and 20,000 tons from England. Supplies from the Ruhr are conveyed almost exclusively by water, about 1,000,000 tons (including 70,000 tons of brown coal) being imported into Strasburg. On the other hand, the greater part of the imports from the Saar were rail-borne. The bulk of the coal delivered was consumed locally, but a considerable tonnage was passed on by water or rail to Lorraine, the neighboring departments of France, and Switzerland. In addition, 500,000 tons of coal from the Saar were conveyed over the Marne-Rhine canal system to the east of France. Inclusion of this tonnage raises the total quantities of coal entering Alsace from Germany to over 3,000,000 tons per annum.

Metallurgical Industries Used Imported Coal

Almost the entire import of fuel into Lorraine was utilized in the metallurgical industries. In 1912 the province received by rail 3,170,000 tons from the Ruhr coal field, of which no less than 3,060,000 tons were coke. There were consumed, in addition, 2,170,000 tons from the Saar (including the mines of Lorraine and the Palatinate), of which only 320,000 tons were coke. Lorraine also received 100,000 tons of coke from France and 330,000 tons of Belgian coke. The consumption of Ruhr coke in Lorraine rose by over 1,000,000 tons in the interval between 1909 and 1912; in particular, the deliveries from the right bank of the Rhine advanced from 1,900,000 tons to 2,900,000 tons. At the same time, the imports of Belgian coke showed a substantial increase in the same period, rising from 177,000 tons to 440,000 tons.

This was the position prior to the war, and it cannot be expected to change materially under present conditions, as the shortage of fuel will persist, and the productive capacity of the French coal fields is expected to fall short of the consumption by some 24,000,000 tons. The Saar collieries produced before the war about 12,000,000 tons, and during the war this fell to 5,000,000 tons. In peace time the Government collieries in this district found a market for 5,000,000 tons, or 70 per cent. of their output, in Prussia and Southern Germany; 1,500,000 tons, or 12 per cent., in Alsace-Lorraine; 1,000,000 tons, or 8 per cent., in France; the remainder being sent to Switzerland, Italy and Belgium. The net result is that, in the acquisition of these mines, France, under normal conditions, gains 8,000,000 tons, or, adding the private mines in Lorraine, 9,000,000 tons; but, in the years immediately following the war, the additional tonnage of coal secured for our allies will not exceed 5,000,000 or 6,000,000 tons, and, consequently, will not be sufficient to make good the deficit of the French collieries.

Furthermore, the Saar mines produce very little coking coals, the coke yielded being of inferior quality. In 1912 the state collieries produced only about 1,600,000 tons of coke, and the private mines about 200,000 tons at the most from a total output of 3,500,000 tons of coal. It was this deficiency that led to enlarged imports of coke from the Ruhr coal field before the war. As it is anticipated that the metallurgical industries in Lorraine will show progressive development, it is essential that Germany should be made to supply large quantities of coke or coking coal, as in the past, and the bulk of this will have to be delivered, via Strasburg, by water.

The proposal is now made that these supplies should be sent in the shape of coking coal, so as to avoid breakage of coke in transshipment at Strasburg and to enable France to recover the byproducts of which she stands so greatly in need. The total requirements are placed at 3,500,000 tons, of which 1,300,000 tons at least would be sent via Strasburg; but it is hoped that this total may be gradually increased.

So long as this town remained in German hands, the distribution of coal for local requirements, amounting to about 600 tons per diem, was exclusively in the hands of the "Kohlenkontor" (the Rhenische Kohlenhandels - und - Rhedereigesellschaft), the sales branch of the Rhenish-Westphalian Syndicate, with headquarters at Mannheim, and a branch office at Strasburg, lately transferred to Kehl, with agencies at Colmar and Mulhouse. The Kohlenkontor dealt direct with large consumers or dealers, but possessed no storage depot at Strasburg, nor any barges on the Rhine, hiring the necessary craft and delivering direct to customers. The State mines in the Saar also dealt direct with large consumers under contract. As regards the private mines, Messrs. de Wendel, before the war, maintained a sales department for their products at Strasburg, the Houve Mines had their business headquarters there, and the Stinnes and Holstenbath Collieries were represented by the Strasburger Kohlenaufbereitungsansalt und Rœchling.

If the Saar mines become the property of France, the headquarters will probably be retained at Saarbrucken under Government control, but it will be necessary, as regards the deliveries from the Ruhr, to establish some organization to take the place of the Kohlenkontor, and to supervise the distribution of coal throughout the provinces of Alsace-Lorraine; the present situation demands that measures to this end should be taken without delay.

Opportunity for American Coal in Canary Islands

Consul George K. Stiles, Teneriffe, is authority for the statement that there seems to be a splendid opportunity for the introduction of American bunker coal on a large scale in two of the more important coaling stations in the South Atlantic—namely, Teneriffe and Las Palmas, Canary Islands. There is no bunker coal on hand, with the exception of a few hundred tons of low-grade Spanish coal reserved for the use of Spanish mail boats between the peninsula and the archipelago. The efforts of the Canary Islands companies, all controlled from London, to obtain British coal have so far resulted in failure on account of the insufficiency of the British supply for home uses.

There is no doubt whatsoever that there is a market for large quantities of American bunker coal as the temporary supply until the mining industry of England has regained more nearly its normal conditions. These islands would undoubtedly absorb a hundred thousand tons of American coal in 1919 for bunker purposes. The temporary opportunity is one that needs no special emphasis. Offers by the local firms at this time for bunker coal c. i. f. Teneriffe are understood to be as high as $35 or $45 per ton, the latter being for steamer delivery. To secure a permanent hold on this trade, valued at $6,000,000 to $10,000,000 a year, would require, however, unusual efforts, as it is dominated by the South Atlantic coaling combine.

The firms in the Canaries are simply departments of London firms, which are the mine owners or are closely affiliated with mine owners. It would seem necessary, then, for American firms to secure concessions and to form a similar trade combination as the already existing British one before the American product would be able to make any showing in that market, even though it could be landed there more cheaply than the British-produced article.

Santa Cruz de Teneriffe and Las Palmas, Grand Canary, are both deep-water ports, ranging from 20 fathoms up. Cargoes range from 2000 to 7000 tons, and other than full cargoes are rarely received there, except a few shipments of gas coal for the use of the Teneriffe and Las Palmas gas companies, which occasionally buy small lots. Anthracite is also occasionally purchased, but the trade is comparatively unimportant, being estimated at less than 5 per cent. of the entire traffic. Coke is practically never imported.

The usual manner of unloading cargoes is to have the coal shoveled into sacks weighing about 200 lb. each. This is transferred to lighters by the derricks of the collier at the rate of five sacks to each shift of the derrick, or approximately one-half ton to each movement of the crane. The ordinary rate of unloading equals 250 tons per day, but as high as 600 tons have been unloaded. This could be doubled by night shifts, if exporters desired to economize the time of the collier's charter. The usual charter calls for unloading at the expense of the consignee.

All coal in Teneriffe and Las Palmas is unloaded into lighters, and exporters should therefore base their prices on contracts requiring merely the delivery of cargoes alongside lighters. The coaling firms all maintain large forces of men to unload and handle their purchases, and a section of the port is occupied by scores of lighters for this service.

The amount in storage at the depots on the shore at Teneriffe approximates normally between 60,000 and 70,000 tons, and practically the same amount is possessed by the coaling firms at Las Palmas.

Spanish Coal Imports

The following tabulation shows the quantity in metric tons (2204.6 lb.) and the value of coal and coke imports into Spain during 1916 and 1917:

	1916		1917	
	Tons	Value	Tons	Value
Coal	2,017,243	$9,440,497	1,094,806	$5,119,433
Coke and briquets	134,047	876,896	73,362	462,181

The lessened importation during 1917 was the natural outcome of the abnormal trade conditions caused by the war. In 1916 the United States exported coal to Spain to a value of $227,611. Great Britain,

as was to be expected, topped the list with coal exports to Spain during 1916 to a value of $9,209,395. France came last, with coal to a value of $5694.

Spain has been forced to rely in large measure on domestic fuel, therefore coal mining has been encouraged in every way possible, with the result that 5,973,300 metric tons of coal of all kinds were mined in 1917, an increase of 1,125,825 tons over the official figures given for 1916. In 1917 the production of soft coal amounted to 5,025,600 tons, lignite to 636,800 tons and anthracite to 310,900 tons.

In many cases the production was checked by the impossibility of transportation, owing to lack of coal cars on the railroads. It is said that near many of the mines there were thousands of tons of coal ready for sale, but that there were no means by which it could be carried away. Mining was paralyzed in some parts also on account of insufficient space in which to store coal.

The progress in Spanish coal mining is indeed all that could be expected, but the supply does not yet meet the industrial demands of the country. It is natural that the increase should continue unless labor should fail, because the mining companies are now supplied with machinery. To encourage mining throughout Spain, the government authorized an organization called the National Council of Coal Miners, the principal objects of which are to group small concessions, investigate new fields, secure mining machinery, build railroads, depots and freight yards, and by concerted action increase the production of coal. Syndicates of mining companies are formed in different localities having the right to representation in the national council based on the quantity of coal produced. The government grants this organization aid by constructing such railroads as may be necessary for the development of coal fields and by advancing funds in the form of loans to groups of mine owners.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report under date of Mar. 24:

As the Chartering Committee will not allow American shippers to charter neutral steamers to carry coal from the United States to ports in Brazil and the River Plata (which boats are consequently chartering from Cardiff to these destinations), and as the Shipping Board is not able to supply enough steamers for these voyages for American shippers' requirements, we suggest to our various shippers that they charter sailing vessels for these voyages.

We have recently chartered a number of sailing vessels for this business and have a few other boats available.

We also have sailing vessels that will entertain coals to outside French ports at $30 per ton net form of charter, and to Marseilles or Genoa at $32.50 net form of charter.

The Shipping Board informs us that the Norwegian-American Sailing Vessel Agreement has terminated, and consequently these vessels are no longer under control of the U. S. Shipping Board or the British Ministry of Shipping.

The Chartering Committee's rates are as quoted below:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge. Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis., or $21 net, 600 tons dis.; Buenos Aires, $18.50 net, 600 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.50 net, 500 tons dis. To Nitrate Range, $16.50 gross prepaid.

Sail (maximum)—Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Rio Grande do Sul, $21.50 net, 400 tons dis.; Buenos Ajres, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. To Nitrate Range, $16.50 gross prepaid.

A cablegram from American Minister Stimson at Buenos Aires, dated Mar. 17, states that he had been informed that the labor unions had consented to return to work under the terms of the decree of the government and that the unloading of vessels in the port would be commenced immediately.

Shanghai Coal Market

Under date of Feb. 12 Wheelock & Co. report that the market for Japanese coal has been practically closed owing to the Chinese New Year holidays, and that it is unlikely there will be much business of any account for some time to come. Native dealers do not seem to be in any hurry to resume work, most of the trades being slack and money very tight.

In Japan the coal market continues firm. All government contracts, such as those for the navy, army, railways, etc., are now being considered—the Japanese fiscal year commencing Apr. 1—and mine owners are being hard put to it to meet the requirements as the demand greatly exceeds the supply.

There is no change in the Fushun coal situation, and no prospects of any coal for export in any quantity before the end of March. Also due to the Chinese holidays there has been little activity in the Kaiping coal market.

Retail Prices of Coal in Wales

Under the Household Fuel and Lighting Order, 1918, the local fuel overseer has fixed the price of household coal delivered in the residential district of Swansea (Sketty and Mumbles) at the following prices per long and short ton:

Quality	Price per Long Ton	Price per Short Ton
Best quality:		
Large and cobbles	$12.41	$11.08
Second quality:		
Large and cobbles	11.68	10.43
Third quality:		
Large and cobbles	11.07	9.88
Anthracite:		
French nuts and cobbles	13.99	12.49
Colliery screened cobbles	14.11	12.60
Large	14.11	12.60
Patent fuel:		
Briquets	10.83	9.67
Ovoids	13.38	11.95

It should be noted that the price of the best quality of anthracite coal delivered inside the residence at Swansea is fixed at $12.60 per ton of 2000 lb. This is an extremely high price when it is considered that Swansea is the centre of the anthracite coal districts of the United Kingdom, the mines being located in some cases within five miles of Swansea.

Italy Demands German Coal

Information comes from official sources that Italy intends to alleviate the extremely acute coal famine from which she has been suffering by demanding coal supplies from Germany by way of indemnity. Unless fuel can be procured in large quantities the national industries of Italy will be paralyzed. British exports of coal are insufficient to meet the demands, while exports from France have ceased entirely.

The Italian Government had hoped that American coal would help solve the fuel problem, but sea-going freight rates make American coal delivered at Genoa dearer than the British, which is selling at about $40 a ton. The lack of bottoms further complicates the situation. Negotiations with American coal exporters have been suspended until the question of obtaining German coal as indemnity is examined.

Miscellaneous Notes

American coal exporters are determined to make a strong effort to retain a big slice of the European coal trade. Orders are reported to have been booked in Sweden, Holland and Italy at low prices.

The London coal market still suffers keenly from short supplies. Many depots are closing their gates early in the day, and the overhanging cloud of labor trouble, with stocks so low, has thrown the market into grave anxiety. The seaborne quantity is improving.

The announcement that the Mexican Government intends to place a heavy duty on imports of coke has caused considerable uneasiness among Mexican importers of the product. They claim that Mexican coke is of an inferior quality and that an import duty on foreign coke would make production costs in the majority of industries prohibitive.

COAL AND COKE NEWS

EDITED BY ALEX MOSS

Harrisburg, Penn.

A state tax of 1 per cent. on the value of the coal mined and prepared for market in Pennsylvania would be established for state purposes only, under the terms of a bill introduced in the House on Mar. 25 by Mr. North of Chester.

The bill would affect both hard and soft coal. The bill is similar to former laws, which it would repeal, and requires production reports to be made to the Auditor General.

It was learned on Mar. 26, that before the Davis Mine Cave Bill is reported out, if this action is taken, the word "coal" will be taken out and "anthracite" substituted. Members of the mines committee from the bituminous region, among whom are Senator W. E. Crow, interested in a number of soft coal operations, have insisted on this amendment, it is said. As the measure reads now, the entire coal industry of the state, anthracite and bituminous, is affected by its provisions. The bill is a drastic one and was drawn up principally to remedy conditions as they exist in Lackawanna County, and for this reason the soft-coal interests have announced their objections to the inclusion of the bituminous industry in the bill.

While drafts of the proposed amendments of the Workmen's Compensation Act are before the Governor and Attorney General for their final determination, and are subject to change, it is understood that the state administration is favorable to the contentions of the coal miners and other organized labor that there should be an increase in the rate of compensation and a change in the "waiting period" from fifteen to seven days. The miners urge 70 per cent. compensation against 50 per cent. of the weekly wage, as at present. Capitol gossip is that the new bill will be either 60 or 65 per cent. Compensation, however, is not to exceed $13 a week, an advance of $3. It is understood that conferences have been had with labor leaders and that while some want to put in their own bill, others are disposed to accept what Chairman Harry A. Mackey has drawn up for the consideration of the Governor.

One of the changes under discussion is the schedule of payments for mutilation and disfigurements, for which the miners have strongly contended. A bill already in provides for medical attention for 30 days instead of 15, and this is also said to be favored by compensation officials. Wider powers for the State Board to fix rates are understood to be included, although there is a difference of opinion on this point.

Leading anthracite coal operators have made overtures to Governor Sproul to submit their books, reports and other data, which, they declare, will show that the proposed increases in the price of coal to take place on May 1 are justified. It is learned that the coal operators favor a "friendly" investigation and that they are doing everything possible to prevent a legislative investigation. It is believed that nothing will be done toward pushing a resolution through the Legislature until after the operators have been given a reasonable time to discuss the situation among themselves and also with the Governor.

Uniontown, Penn.

"Hold wages up and production down," may be defined as the general policy of independent (or merchant) operations of the Connellsville region, expressed and approved at a conference of operators here which marked the first meeting of the Coke Producers' Association since before the war. That agency, long inactive, is to be called back to life to direct the coke industry through the crucial days ahead in the stabilization of the industry.

Various operators at the conference were emphatic in approving a decision not to disturb the wage scale so long as the cost of living remains at its present level. To attain that end, it was held the coke market must at least be kept firm; and to keep an active demand for Connellsville coke there seems to be no limit to the lengths to which the operators will go. With an average price now of $4.50, ovens, many operators dealing in prompt delivery frankly asserted their intention of suspending operations if the spot market went below that price.

That the turning point in this region is now near, and that it actually has been passed in the country at large, was the assertion of W. L. Byers, production manager for the fuel administration during the war. Quoting Washington advices, Mr. Byers asserted that consumption of coal and coke in the country now exceeded production by 20 per cent., and that unless some move was soon made toward increasing output a marked scarcity would be found in the market for fall and winter buying. Speaking of his experience as a coal and coke broker, Mr. Byers said that the situation was now being appreciated by buyers and that inquiries had made an encouraging increase during the past week.

A warning was given the operators not to expect too much business from the Great Lakes trade now opening up, by Fred P. Truesdale, former division freight agent for the Pennsylvania R. R. Mr. Truesdale said that a mild winter had left consumers with stock piles which must be reduced before the demand becomes active from that source.

Charleston, W. Va.

Insofar as it is possible to determine, taking West Virginia as a whole, there was a slight gain in production during the week ending Mar. 22, the increase, such as it was, being due to larger shipments to the West. Even there, however, the demand is far from being sufficient to give much impetus to mining in those fields of West Virginia which depend on the West for their market. The fact that there is and has been less activity in the Western market than was expected is attributed by West Virginia operators to the prospects of a dull lake trade during the early part of the season. In fact, West Virginia producers are inclined to believe that it will be well onto a month before there is any appreciable carrying of coal on the lakes, owing to the fact that lake consumers have a surplus of about four million tons to draw upon.

Stock piles in Western markets are being somewhat diminished, but the process is so gradual that it does not require much to replenish them. Even those districts shipping to the East during the third week of the month for the most part were still looking to the West to supplement the demand and to make possible production on more than a 50 per cent. basis, because tidewater shipments were just about stationary, with no export business at all in sight. The only coal which was going to the West in any volume was lump and egg, and lack of equipment and storage facilities made it hard to mine that coal because of the necessity of taking out other coal at the same time. However, for the reason just stated, there was a better demand in the West. Navy consumption is helping to swell shipments from certain districts.

DuQuoin, Ill.

The Kathleen mine, at Dowell, five miles south of Du Quoin, owned by the Union Colliery Co., of St. Louis, is fast nearing completion. The mine, which was started one year ago, will be the largest bituminous coal mine in existence, when completed. The property on which the mine was sunk lies on the main line of the Illinois Central Railroad Co., 1½ miles north of Elkville and five miles south of Du Quoin. This place, eighteen months ago, was a bare tract of land, but today is a thriving mining town of 500 to 600 population.

Over the main shaft of the mine, which is 28 x 19 ft. clear, is being built the largest steel tipple ever constructed, and at the air shaft, which is 33 x 10 ft. clear, a concrete tipple has been completed with a double-deck 50-man cage in operation. It is at this shaft that all the men and materials will be hoisted and lowered.

At the present time 900 to 1000 tons are being hoisted each day, but when in full operation it is expected that the plant will reach a tonnage of 6000 to 8000 daily. The power throughout the mine is electric, including all haulage, mining machines and hoisting, the method employed in hoisting the coal to the surface being by means of skip hoists holding 10 tons each. From 1000 to 1300 men will be employed in the mine when it is running full blast.

The Illinois Central Railroad Co. has announced the opening of its new five-stall roundhouse and machine shops, which it has completed at the north end of the city switchyards. This represents one of the biggest railroad improvements made in Du Quoin for years, and one which this city with its greatly increased freight and coal traffic sorely needed.

The United States Fuel Co. has completed 50 modern homes at Benton, east of here, to be used by the employees of the Middle Fork mine. On account of the scarcity of men last year the company purchased land just inside the city limits and erected houses.

The possibility of a coöperative store in this city is being discussed by the miners' unions, and the discussions have so far indicated it is likely the plan will go through. The stock of goods will be purchased through the East St. Louis offices of the Illinois Coöperative Store System, which has jurisdiction over the miners' store of Southern Illinois.

New York, N. Y.

The ratification by the General Strike committee of the Marine Workers' Affiliation of the settlement made between the private boat owners and the members of the Tidewater Boatmen's Union obviates, at least for the present, all danger of a coal famine in the Metropolitan District. The striking harbor workers at the outset of the trouble, about five weeks ago, numbered nearly 16,000. Almost half of these returned to work when Government departments, including the Railroad Administration, granted the strikers' terms, and the remainder of the men have been holding out for their terms.

During the past week the situation became serious. Retail dealers were running short of coal, and it was said that some of the city institutions were also suffering from the lack of coal. Dr. Garfield, Federal Fuel Administrator, sent a telegram to Mayor Hylan in which he suggested to the Mayor the possibility of supplying facilities for the movement of coal so that the public service corporations would not suffer.

The offer of the private boat owners took with it an increase in salary of $20 a month over what the tidewater men received before the inauguration of the strike, making their pay $110 a month. There was no suggestion of a decrease in working hours. The Railroad Administration settled its differences with the tidewater men on the same salary terms, but granted a twelve-hour day and $1.50 per night for watchmen's duty on loaded barges. The tidewater men originally asked for $125 per month, with no provision for shorter hours.

Private boat owners, individually, believe the strike is won and do not expect any further trouble. By the end of the week they expect that most of the coal barges will be running and that there will need be no further fear of a coal shortage.

Victoria, B. C.

The production of the collieries of Vancouver Island for the month of February totaled 145,750 tons in comparison with 158,327 tons for the month of January. It should be borne in mind, however, that February is the shorter month. Still this does not altogether account for the decline. Nanoose collieries, for instance, dropped to an output of 500 tons, which is explained by the interference with work caused by the construction of a wharf. While the generally changed conditions of the past six months have had no noticeable effect on the Island collieries as yet, the producing mines being operated steadily and in most cases to capacity with

results even better than when the war demand was at its height, there are slight indications that the urgency for output is not as great as it was. The work of opening up the Wakesiah Mine, which is situated near Nanaimo, B. C., and owned by the Canadian Western Fuel Co., has ceased temporarily, and a short time ago the coal miners of Nanaimo were off for a Saturday afternoon.

Both the Princeton Collieries and the Coalmont Collieries have increased their production in comparison with the results of January. In the case of Princeton the explanation of the improvement is that in the previous month a fire interfered with work.

As for the Crowsnest Pass coal field, there are no returns to hand as yet. The collieries, however, are authentically said to have operated only twelve days. A substantial reduction, therefore, is looked for. The reason for this slackness is found in the lack of demand in British Columbia for coke, following the closing down of the smelteries at Greenwood and at Anyox, particularly that of the Granby Consolidated Mining and Smelting Co. at the latter place, where a large quantity of the fuel is used when the plant is working to full capacity.

PENNSYLVANIA

Anthracite

Marysville—The river coal trade along the Susquehanna in Perry County promises to be an important industry next summer, due to the high prices being paid for coal. All along the river men who have been in this trade in the past are calking their old barges and preparing for a big summer business.

Hazleton—At a meeting of the stockholders of the New York and Lehigh Coal Co. on Mar. 20, the corporation was dissolved. It was one of the oldest concerns in the anthracite field. All the mining rights have been sold to the Lehigh Valley Coal Co.

Carbondale—New York capitalists have purchased the Horseshoe Bluff of the old gravity railroad for $95,000 and will market the coal used in the filling of the bluff many years ago. Also, the Lackawanna Coal Co., Ltd., has purchased from the Jordan McNally Co. the Northeast Colliery. This plant contains about 2,000,000 tons of coal.

Plymouth—The Hudson Coal Co. has under erection at this place the largest capacity breaker building in the anthracite field. It will be up to date in every way. It is the first breaker building to be covered, both roof and sides, with protected metal. The development and operation of this breaker will be followed with interest, as the plant establishes a precedent in the field due to the features embodied in its construction.

Bituminous

Pittsburgh—The Roberts & Schaefer Co., of Chicago, has been awarded a contract for the installation of shaker loading booms at each of the Primrose and Armeid tipples of the Carnegie Coal Co.

Brownsville—The Snowdon Coke Co., operating near Brownsville, on the Pennsylvania R. R., is putting 50 ovens out of blast. This will leave 160 ovens in blast and permit the mine to operate about three-fourths time with the present working force.

Braznell—The Pittsburgh Steel Co., which has taken over the coal and coke operations of W. Harry Brown in Fayette and Green Counties, is preparing to speed up these operations. Of a total of 400 ovens, 200 are now in operation; 185 more will be fired up, 15 being kept out for repairs which will be pushed as rapidly as possible.

WEST VIRGINIA

Beckley—A property loss of about $10,000, fully covered by insurance, was sustained by the Tolbert Smokeless Coal Co., recently, when the building which housed its store and office was burned to the ground, the fire spreading so rapidly before being discovered as to make it impossible to save the structure.

Mt. Hope—The plant of the Mt. Hope Coal and Coke Co. is a total loss as the result of a fire which not only destroyed the tipple and other mining buildings but also the company's ice plant, the loss being about $30,000, nearly half covered by insurance. Mine cars and other equipment were also destroyed in the fire. The plant had not been in operation recently, but the company's ice plant did furnish ice for local consumption, and had just placed an order for new machinery. The Mt. Hope company belonged to W. E. Deegans and his associates. It will hardly be rebuilt.

Williamson—A coal deal of considerable magnitude has been closed in Mingo County, in which the change in ownership of 1500 acres of coal land is involved, the price being in the neighborhood of $150,000, it is said. The purchasers are M. H. Pedigo, of Bluefield, and his associates, the coal property acquired from E. E. Music being on Pigeon Creek. Col. William Leckie, of the Pocahontas field, is one of those associated with Mr. Pedigo in the Pigeon Creek deal. It is the expectation of the purchasers, so far as plans have been made, to develop the territory whenever general conditions seem favorable. The United Thackers interests only a few years ago acquired a large acreage from Mr. Music, who has now disposed of all his coal holdings.

KENTUCKY

Madisonville—The St. Bernard Mining Co. is making rapid progress on its new power plant, which will furnish power and light to a number of mines and towns. Poles and wires are up to some of the mines, the transmission lines having been completed to the Fox Run mine at St. Charles and the Diamond mine at Morton's Gap.

OHIO

Carrington—The Sunday Creek Coal Co. of Columbus, recently reorganized, is going ahead with its improvements and betterments, on its properties in the Hocking Valley field. A new tipple is being constructed at Mine No. 90 at this place, and preparations have been made to build new tipples at Mine No. 19, Buckingham, and Mine No. 10, at Glouster. All the tipples are of steel construction. Shaker screens and other modern equipment will be installed.

INDIANA

Bridgeton—The recent heavy rains have caused a serious cave-in at No. 6 Zellar-McClellan coal mine, damaged the pump, placed the hoisting machine out of commission and caused a shut-down of the mine. Repair work is being pushed but it will be two weeks before the mine can be operated again. The cave-in happened when only one man was in the mine, and fortunately he escaped by way of the manhole. The mine is located southeast of Bridgeton.

Brazil—Officials of the Pennsylvania R.R. announced that beginning Monday, Mar. 31, after the clocks are advanced one hour, the Seelyville and Glen Ayr miners' train would be run one hour later. The miners' train now leaves Harmony at 5:40 in the morning and Brazil at 5:50, but beginning on Mar. 31 the train will leave Harmony at 6:40 and Brazil at 6:55 o'clock. The miners objected to arising an hour earlier, and district officials took the matter up with the railroad company which agreed to run the train an hour later. The return trip in the evening will also be made an hour later.

ILLINOIS

Litchfield—The Chicago, Burlington & Quincy R.R. has opened a new coal mine at Vallier, south of Litchfield, and is building the foundation for a town which is expected to grow rapidly. The Burlington is building a double track between Reno and Durley.

Peoria—The Crescent Coal Mining Co., operator of large mining interests south of Peoria, has secured the mineral rights to 160 acres of land in Hollis township, a few miles from the city of Peoria. The land is owned by Emil and Margaretha Stoll, the company paying $5000 for the right to mine the coal beneath the land.

Hillsboro—A syndicate which is reported to be backed by Gary, Ind., interests, has been obtaining options on a large body of coal lands between Hillsboro and Walshville. It is understood that the plan is to obtain options on at least 35,000 acres running southwest from Hillsboro to the vicinity of Walshville. The options run six years.

Carlinville—Another large coal field, embracing some 1500 acres, located in Macoupin County, has been sold. This field lies between Bunker Hill and Shipman, and as many of the other fields in this country, its sale was promoted by A. W. Crawford, of Hillsboro. Mr. Crawford secured the options on this field recently and drills have been testing the quality and quantity of coal. It is considered that this new field will not be extensively worked for at least two years.

TEXAS

Rockdale—The Federal Fuel Co. has been organized for the purpose of developing a large tract of lignite lands near Rockdale, Texas, in Cameron County. Organizers of the company are Henry G. Butler, of Hillsboro, Tex., vice-president and general manager; W. A. Butler, also of Hillsboro, and William Butler, of San Marcos. Offices of the company are maintained at 1003 Scanlon Building, Houston, Tex. The company owns 1400 acres of lignite lands southwest of Rockdale, which is underlaid with more than twenty million tons of lignite, according to estimates prepared by engineers. Much of this lignite lies sufficiently close to the surface that it can be mined by steam shovels in stripping operation. The company will build seven miles of its own track from the International and Great Northern, which will traverse the 1400 acre tract. It is planned to have the mine in operation by Aug. 1, with a daily output of 1000 tons.

MONTANA

Musselshell—On Mar. 17 the Star coal mine filed with the county clerk at Roundup a certificate authorizing the increase of its capital stock from $150,000 to $200,000. The company contemplates extensive improvements to its mine here. The operation has been producing coal for several years.

Roundup—If William Degan of this city is able to carry out his plan the old Keene coal property, a few miles west of here, will again be operated. The mine has been idle since it was abandoned four years ago by Nelson Brothers. There are a number of judgments against the property, and Mr. Degan hopes to be able to operate on a royalty basis, paying the creditors a certain sum for each ton of coal mined. The creditors are said to be in favor of the plan.

Foreign News

London, England—The sum of £15,000 is being devoted by the British Government toward the cost of experimental borings in the County Tyrone coal field, which has the town of Coalisland for its chief center. The borings are being made in the vicinity of Lough Neagh, under which coal is supposed to lie. The experimental borings are being carried out under the advice of experts from the English coal fields, under the supervision of Sir Lionel Phillips.

Calgary, Alberta—At the annual convention of the British Columbia Federation of Labor held here recently, resolutions were passed asking the British Columbia Government to order inquiries into the coal mine accidents of 1916 at Coal Creek and 1918 at Nanaimo, which resulted in the deaths of 48 miners. The convention was assured that the Provincial Government was prepared to proceed with any further investigation that might be considered necessary.

Ottawa, Ont.—C. A. Magrath, Fuel Controller for Canada, announces that the fuel situation has now cleared up to such an extent that the organization in Ottawa will terminate its activities at the end of the present month. Ample supplies of coal are now available for both domestic and industrial purposes, production for all classes of coal having overtaken the demand. The coal regulations will probably be allowed to remain in force until the actual declaration of peace, although importers and dealers will not be required to take out new licenses for the coming coal year. The Controller stated that this would be his last official statement to the press and desired to emphasize the desirability of everyone taking in coal supplies who could afford to do so in the near future. There was a disposition to hold back in the anticipation that prices will come down. While he was unable to make any positive statement as to prices, the tendency so far as anthracite is concerned seemed to be in the other direction. One or two of the large United States coal companies have announced that the usual opening reduction will not be made, and that prices will advance at the rate of 10c. per ton each month for five months during the summer.

Personals

J. B. Marks has been appointed to the position of purchasing agent of the Colorado Fuel and Iron Co., of Denver, Colo., vice **S. G. Pierson**, elected treasurer.

R. L. Baker, formerly connected with the Railway and Mine Supply Co., is now the

Chicago sales representative of the Muskegon Boiler Works, of Muskegon, Mich.

George T. McCarty, of Pittsburgh, Penn., has resigned as manager of western sales of the United Coal Corporation, effective Apr. 1, and will engage in the coal brokerage business in Pittsburgh.

C. G. Knisley, who has been secretary and general manager of the Reeves Coal Co., New Philadelphia, Ohio, for the past nine years, has resigned his position to assume his duties as vice president and secretary of the Midvale Coal Company.

William Lahm has resigned his position as superintendent of the Ellsworth Collieries Co., Ellsworth, Penn., to become general superintendent of the Washington Coal and Coke Co., with headquarters at Star Junction, Penn., effective Mar. 15.

H. G. Lewis, sales manager of the Electric Service Supplies Co., Philadelphia, Penn., has recently been made vice president. Mr. Lewis is well known in the eletcric railway, mining and power fields. He will continue his work as vice president and sales manager.

John Hanwell, of Bismarck, N. D., has been appointed state mine inspector, in pursuance of a new law enacted by the recently adjourned session of the legislature of the State of North Dakota. The duties of mine inspector were formerly covered by Jay W. Bliss, state engineer.

C. E. Hague, formerly production engineer of the Mid-West Engine Co., Indianapolis, Ind., has been appointed sales manager of the American Steam Conveyor Corporation, Chicago, manufacturers of the American steam ash conveyor and other ash-handling equipment. Mr. Hague assumed his duties Mar. 17.

Thomas Haulton, well known mechanical and electrical engineer, has opened an office in Johnstown, Penn., as a consulting engineer, specializing on mining equipment. An interesting feature in connection with a service for coal operators that Mr. Haulton is going to inaugurate is an arrangement whereby Mr. Haulton, in return for a reasonable stipulated monthly fee, will be available to mine managements at all times for information and advice. Mr. Haulton's long and varied experience with all classes of mining equipment in this and foreign countries, especially fit him for this service.

E. E. Back, formerly sociological director of the Ellsworth Collieries Co. and recently Chief of the Americanization Bureau of the Council of National Defense, has accepted a similar position for the State of Pennsylvania under Governor Sproul. His work will relate not only to the teaching of English to aliens and their acquirement of American citizenship, but also to health, safety and other welfare. Inquiries and suggestions relative to this work will be welcomed by Mr. Bach, whose address will be the 7th floor, Finance Building, Philadelphia, Penn. He will be assisted by a body of experts in all lines to be covered.

Obituary

George H. Lacey, general superintendent of the LaSalle Mining Co., LaSalle, Ill., for a number of years, died at the age of 86 years at Southern Pines, N. C. He was formerly mayor of LaSalle, Illinois.

Whiteman E. Smith, aged 39, president of the Smith-Gardner Coal Co., died in Cincinnati, Ohio, recently from pneumonia. He was the grandson of the late Richard Smith, who was editor of the Cincinnati "Commercial Gazette" for many years.

Coming Meetings

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Illinois Mining Institute will hold its annual meeting May 22, 23 and 24. Secretary, Martin Bolt, Springfield, Ill.

National Coal Association will meet May 21, 22 and 23, at Congress Hotel, Chicago, Ill. Secretary, J. D. A. Morrow, Washington, D. C.

International Railway Fuel Association will hold its annual meeting May 19-22 at the Hotel Sherman, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

Indiana Retail Coal Merchants' Association will hold its annual spring meeting Apr. 23 and 24 at Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

Industrial News

Canton, Ohio—The George A. Williams Coal Co. has been incorporated with a capital of $20,000 by George A. Williams, Charles C. Upham, Nelle M. Meysr, W. G. Brossman and J. G. Kramer.

Louisville, Ky.—The Gordon-Miller Coal and Coke Co., Louisville, has filed amended articles of incorporation, increasing the capital stock from $80,000 to $250,000. The company has mines in eastern Kentucky and offices in the Lincoln Bank Building, Louisville.

Dalton, Ga.—The Jacobs-Glaser Mining Co., which recently filed notice with the Secretary of State of a change in its corporate name to the Coosawattee Coal and Mining Co., has increased its capitalization from $200,000 to $500,000, to be used, it is understood, to provide for expansion.

New York, N. Y.—A. H. Smith, Regional Director of Railroads, Eastern Territory, shows in his report for January and February that compared with the same months in 1918, bituminous coal loading decreased 43 per cent.; and that anthracite coal loading for January decreased 2 per cent. and in February 30 per cent.

Huntington, W. Va.—D. E. Hewitt & Co. of this city have acquired 1500 acres of coal land from the Berger estate near Kermit, W. Va., and plan development when the time seems ripe to expend about $150,000 in installing a plant for the mining and shipment of coal. Associated with D E. Hewitt are Arch Hewitt and R. A. Thomas.

Charleston, W. Va.—Capitalized at $150,000, the Nelson Coal and Oil Co. has been organized, the company being incorporated by Charleston citizens. It is the intention of the organizers to do a general mining business. Chiefly interested in the formation of the company were J. M. Clark, E. M. Johnson, G. R. Krebs, C. W. Morton and C. E. Krebs.

Columbus, Ohio—George A. Borden, president of the Columbus Board of Purchase, will open bids Apr. 7 for the purchase of 1400 tons of either nut, pea and slack or mine-run for the garbage and refuse plant; 2000 tons of nut, pea and slack for the waterworks department; and 3500 tons of Hocking nut, pea and slack for the municipal light plant.

Pittsburgh, Penn. — The Epping-Carpenter Pump Co. announces the appointment of F. S. Healey as manager of sales in addition to his former office of chief engineer, vice E. F. Woods, who is now located in New York as eastern sales manager. Albert A. Scheuch, of the sales department, has been appointed as assistant sales manager, and Paul D. Goodman, formerly of the McClary Jemison Machinery Co., of Birmingham, Ala., has been added to the sales personnel.

Duluth, Minn.—The Clarkson Coal and Dock Co. has arranged to make improvements at its dock this season that will result in doubling its handling capacity and entail an expenditure of $125,000. Work will probably be started by May 1, and it is expected that the new equipment will be ready for operation by July 1. When completed the doek will have a loading capacity of 150 cars daily. The contract for the installation has been let to the Mead-Morrison Manufacturing Company.

New York, N. Y.—Through the Bureau of Foreign and Domestic Commerce, we are in receipt of information about foreign trade opportunity number 28,705. W. H. Lane, 101 Queen St., Melbourne, Australia, wishes to secure agencies for mining machinery, high speed engines, boilers, electrical generators, electrical and mechanical equipment of all kinds for timber and mining enterprises. References: J. C. Haskins & Co., Sidney, N. S. W.; Dalgety & Co., Melbourne; and The National Bank of Australia, Melbourne.

New York, N. Y.—The committee appointed to revise the rules of the Tidewater Coal Exchange and to establish a new system of classifications met in Philadelphia Mar. 28 and completed its report, which was sent to J. W. Howe, Commissioner of the Exchange at Washington. A copy of the report will be sent to the secretary of each coal merchants' association for consideration of its members. It is understood that various changes have been recommended in the rules and that the committee recommends that the coals in the pools be classified according to analysis.

Washington, D. C.—The Government plans to sell at prevailing market prices the surplus stock of 80 lb. rail and 25 lb. rail ordered for the American Expeditionary Forces overseas, but not required due to the signing of the armistice. There are about 50,000 tons of 80 lb. rail and about 7000 tons of 25 lb. rail. There are large quantities of crossings, slip switches and turnouts. Most of this material is at port readily accessible for loading. All sales are being conducted through the office of the Director General of Military Railways, Washington, D. C., where further information can be obtained.

Birmingham, Ala.—A committee of Alabama coal men, headed by S. L. Kerkes, of the Grider Sales Co., and W. C. Adams, of Adams, Rowe & Norman, Inc., appeared before the officials of the railroad administration in Washington recently seeking the establishment of a joint rail and water rate from points in the Warrior coal fields to Mobile and New Orleans. The naming of such rates is essential to the proper utilization of the facilities of water transportation on the Warrior, which the Government has made available by the expenditure of vast sums on locks and dams, and to the development of the bunker and export trade which should be supplied from this field.

Columbus, Ohio—Coal-carrying railroads that were permitted to charge $1 per ton for transporting coal from Nelsonville to Toledo after the state public utilities commission in 1911 had reduced the rate to 85c. must refund the entire amount of overcharge and are not limited to liability only of $25,000, the amount of the bond required, according to a recent decision of the Ohio Supreme Court. The cases decided were those brought by the New Pittsburgh Coal Co. and the Big Four Coal Co. against the Hocking Valley Railway Co. The common pleas courts of both Lucas and Franklin Counties had held in favor of the railroads, but the Appellate Court reversed the lower tribunals and held in favor of the coal companies. Many other suits are pending.

Kansas City, Mo.—The board of directors of the Chamber of Commerce has declined to give approval of a request which Kansas coal operators will make before the Interstate Commerce Commission for a 10c. increase in freight rates on coal from the Illinois coal fields. The Kansas operators presented their side of the case, while industrial companies of Kansas City opposed the change. Representatives of local industrial concerns pointed out the present advantage of 60c. the Kansas operators have in freight rates, stating a further advantage would be prohibitive to Illinois coal producers. The failure of Kansas operators to supply local demands was noted by the industrial representatives, who declared the increase of Illinois freight rate, by excluding Illinois coal, would create a serious shortage here.

Indianapolis, Ind.—Alfred M. Ogle is president of the Ogle Coal Co., which has recently been incorporated. The new company will take over the selling agency of the Vandalia Co., which will be operated only as a producing company. The Ogle Coal Co. will also handle the sales of the Atlas Coal Co. and the Vigo Mining Co. The offices of the company will be in the suite in the Fletcher Trust Co. building, Indianapolis, which has been occupied by the Vandalia Co. Mr. Ogle was an assistant to Dr. H. A. Garfield, Federal Fuel Administrator, and had charge of distribution of coal in Indiana. He is widely known in Indiana coal and mining circles and with the passing of the war period wishes to head his own company. Bernard R. Batty is vice president of the company and W. C. Kaiser is secretary.

Louisville, Ky.—The Louisville coal trade is aroused over an announcement of the City Administration of Licenses that the trade is to be taxed, the city alleging that such action is necessary to make up for the loss of revenue when the saloons close. Every branch of the coal trade is taxed, and all promotors are taxed. Extra taxes are arranged for each branch yard, and special taxes for each team or truck. The ordinance as written would also impose special licenses on concerns on the basis of the number of men employed. The coal schedule imposes a license of $100 for each yard, and a scale of payments based on annual business, calling for $7.50 for a $3000 business, and $45 for a business of $15,000 or over in gross sales. The ordinance as written would prove a great hardship on some of the larger concerns which have numerous yards, trucks and employees.

MARKET DEPARTMENT

EDITED BY ALEX MOSS

Weekly Review

Coal Market Shows Signs of Improvement—Considerable Contract Inquiry—Labor Troubles at Mines—Railroad Fuel Controversy Still Unsettled—New England Overstocked—Soft Coal Consumption Exceeds Production—Anthracite Situation Better

BOTH pessimist and optimist can find enough in the present condition of the coal market to bolster up their respective views. A careful analysis, however, would indicate that the optimist has a shade the better right to his belief. Market conditions are a trifle more favorable than they have been, though the demand for coal continues to be extremely dull.

Consumers of bituminous coal are evidencing considerable interest in contracts to cover their requirements for the new coal year, but the majority of the large producers are not at all eager to sign up for this business. The labor situation in most of the important soft coal mining regions is anything but satisfactory, though labor leaders are understood to be assiduous in pointing out to their men that decreased production is essential to the maintenance of prices, and in turn of wages.

All indications at this time point to labor troubles at the mines when the peace treaty is signed, and if these eventuate in any of the fields it will have a tendency to raise the prices of coal in those producing districts that are not affected. Consumers who are not protected by contract will be compelled to meet this advance in price if they wish to obtain coal.

The question of what price the railroads are to pay for their coal is still unsettled. It is believed, however, that a definite understanding will be reached by the end of April. The railroads consume more coal than any other industry, and once the existing controversy between the operators and the railroad officials is eliminated, it will give a feeling of confidence to the entire coal industry. Another reassuring sign pointed out by the optimist is that general manufacturing and industrial conditions appear to be more stabilized. Plants that were practically at a standstill two or three weeks ago are now fairly active.

Not to crowd the pessimist entirely out of the discussion, we will permit him to point out that the New England fuel situation is not favorable to the bituminous coal operator. Stocks in that territory are not being depleted as fast as was expected. The textile manufacturers are apparently no nearer a solution of their labor difficulties, and several large mills are still closed down. Many mill owners, the gloomy prognosticator has discovered, have been obliged to refuse their February and March coal quotas on contracts now expiring. Another factor that disturbs the pessimist is the extent to which fuel oil is making inroads on steam coal in the New England states. In one case, he emphasizes, the change to oil has reduced the coal consumption nearly 50,000 tons.

Conditions in the coal-producing regions of the Middle West are improving. According to reports from Minnesota, Iowa, Wisconsin, Illinois and Michigan, soft coal is being bought in more liberal quantities than heretofore.

Consumption of bituminous coal now exceeds production by 20 per cent. Unless sufficient demand sets in to stimulate output, a marked scarcity will be manifest in soft coal next fall and winter. The many inquiries regarding contracts would lead one to believe that consumers are now sensing the true situation.

The anthracite industry is in good shape, all things being considered. Demand has improved, and this has been reflected in increased working time at the mines. There is no great surplus of the steam sizes of anthracite; and as with bituminous coal, unless production increases considerably from week to week, there is likely to be a shortage. This can be obviated if consumers order their coal early and get it into their bins during the summer months. Household consumers will doubtless put in their orders during the month of April, for an increase in price of 10c. a ton goes into effect on May 1.

WEEKLY COAL PRODUCTION

The loss of time on St. Patrick's Day, Mar. 17, brought about a 7 per cent. decrease in the output of bituminous coal during the week ended Mar. 22, compared with the week ended Mar. 15. The production during the current week is estimated at 7,477,000 net tons as compared with 8,042,000 net tons during the week of Mar. 15 and 11,121,000 net tons during the corresponding week of last year. The daily average per working day is estimated at 1,246,000 net tons and is considerably behind the daily average per working day during the present coal year to date, estimated at 1,795,000 net tons, and last year estimated at 1,762,000 net tons. The total production from Apr. 1, 1918, to date is estimated at 549,126,000 net tons as against 539,127,000 net tons during the preceding year.

The production of anthracite in the United States during the week ended Mar. 22 is estimated at 1,171,000 net tons, as against 1,206,000 net tons during the week ended Mar. 15 and 2,099,000 net tons during the corresponding week of 1918. The daily average per working day during the current week is estimated at 195,000 net tons, as compared with 296,000 net tons for the coal year to date, and 319,000 net tons for the same period last year. The production from Apr. 1, 1918, to date is estimated at 90,488,000 net tons and is 6,981,000 net tons behind the production of the 1918 coal year.

Tidewater shipments to New England, during the week under review are estimated at 93,376 net tons and exceed the tonnage loaded during the week preceding by 13.4 per cent. Considerable improvement occurred during the week in tonnage loaded at New York and Philadelphia, while the tonnage loaded at Hampton Roads decreased slightly. The rail shipments to New England were not reported.

The shipments of bituminous coal from the tidewater harbors to all points during the week ended Mar. 22 are estimated at 362,865 net tons and are in excess of shipments during the week ended Mar. 15 by 12.4 per cent. Tonnage loaded at New York and Philadelphia during the week ended Mar. 22 amounted to 155,111 net tons, as against 113,056 net tons during the week ended Mar. 15. The tonnage loaded at Hampton Roads was also in excess of that reported during the week of Mar. 15, while a slight decrease occurred in the tonnage loaded at Baltimore.

The production of beehive coke in the United States during the week ended Mar. 22 is estimated at 404,242 net tons as compared with 429,446 net tons during the week ending Mar. 15 and 623,927 net tons during the corresponding week of 1918. Production in Virginia, Kentucky, Washington and Utah was slightly in excess of that reported for the week preceding, while in other states production was somewhat lower than the output during the week of Mar. 15. The daily average per working day during the week ended Mar. 22 is estimated at 67,370 net tons, as against 70,175 net tons for the calendar year to date and 81,162 net tons for the same period of 1918. Total production of beehive coke for the period Jan. 1 to date is estimated at 5,614,012 net tons and is considerably below the production during the same period of 1918, when the output was estimated at 6,493,029 net tons.

BUSINESS OPINIONS

Dry Goods Economist—The general condition of trade in retail dry goods and department stores throughout the country, as expressed by visiting buyers, is one of extreme optimism, based on indications in every center that industry is becoming steadily entrenched in a more stable position. Labor disturbances are losing weight and force, while the agricultural situation continues to hold exceptional promise in many sections.

Marshall Field & Co.—Current wholesale distribution of dry goods is running much less than the very large volume of the corresponding week of 1918. Road sales for immediate delivery are well up to the total of last year. Fall business is spotted, handkerchiefs are selling well and many orders for blankets are larger. Retailers continue to visit the market in large numbers, replenishing stocks depleted by excellent business. Collections are satisfactory.

The Iron Age—The opinion is general in the steel trade that the reduced prices announced by the Industrial Board at Washington on March 20 will bring out in the near future a moderate amount of new business, most of which buyers have held up since the stabilizing movement loomed up six weeks ago. The reductions range from $4.25 per ton on pig iron and $5 on billets to $10 on standard rails, and amount to $7 per net ton on plates, shapes, bars, wrought pipe, sheets and tin plate and to $5 on wire, wire nails, hoops and light rails. Eastern bar iron makers have met the reduction on steel bars, dropping their price from 2.90c. to 2.35c., Pittsburgh.

American Wool and Cotton Reporter—Optimism in the wool trade still continues. The mills are demanding wools with which to fill actual orders but are not generally anticipating wants far ahead. The general market for wool is good owing to the purchases of civilian goods. While there is an undercurrent of optimism for the future of cotton, the present actual business to the mills is quiet. There is, however, a little better feeling than there was, and while mill interests are not overconfident for the immediate future they feel the country is bare of manufactured goods. During the last fortnight or so there has been more inquiry and a small amount of "dribbling business" to the mills.

Bradstreet's—Factors of the week in purely domestic trade circles have included enlarged buying both at wholesale and retail; reports of excellent moisture, soil and winter-wheat crop conditions; the beginning of spring-wheat seeding in the southern areas of the northwest; more life in building trades and in lumber and in other materials; preparations making for an early opening of navigation on the Great Lakes; good sentimental effects from and some enlargement of actual buying of iron and steel following last week's cut in prices; larger than expected demand for desirable grades of wool at the Government auctions; a continuance of the gains shown in clearings as compared with a year ago, and a slight cutting down of the unemployment totals, this latter news being accompanied by reports from the northwest and south that in those sections unemployment is negligible, or that an actual need of labor, especially farm help, is already perceptible.

Atlantic Seaboard

BOSTON

Disquieting factors. Railroad fuel problem has its local phase. Few purchases except of specialties. April and May orders scarce. New England tonnage for 1919 sure to be light. Hampton Roads coals dull. Shipping Board adheres to $2.50 rate. Fuel oil a factor. Mixed situation at New York piers. Special rate rumored on railroad fuel by water. Anthracite demand continues light. Scattered inquiry for coal is privately owned barges. Weather helps retail trade. Buyers wait for correction in rates.

Bituminous—The uncertainties seem to have been accentuated the past few days. Indeed there is distinctly a weaker tone to the current market than was noticed a week ago. There is less faith in quotations for early shipment, concessions are so freely made on all the medium grades. Operators are striving to keep their men, but because of heavy stocks on hand New England consumers for the most part find themselves in no position to support producers who want to move coal. Any canvass of the trade discloses a surprisingly heavy tonnage in storage, and curtailments in the different lines of manufacturing are so general and so drastic that it will be July and August, if then, before anything like active buying will develop. The outlook is not encouraging from a trade standpoint, and there can be no hope of large tonnages and comprehensive buying so long as the industrial situation remains in its present posture.

Recent prices to the railroads show the effect of present conditions, and in no uncertain fashion. Bids to furnish one of the New England roads a stated tonnage for April range from $1.60 per net ton on Fairmont to $1.85 on coal from the Greensburg district. These prices are so much lower than the current quotations in the open market that they are bound to react unfavorably on buyers who were considering purchases for the next 60 days. Advantage has been taken of the urgent situation facing certain operators, and it is particularly unfortunate because consumers in this territory are to slow to realize the difference between the spot market and offerings for deferred or season delivery.

Aside from scattered buying of relatively small lots for shipment during the next few months, the only transactions are on special grades for season delivery. As previously reported these are in usual channels, and notwithstanding the extent to which most of the shippers failed for one reason or another to make deliveries last year there appears to have been little shifting from one source of supply to another. Most of these renewals have been made on the basis of $2.95 per net ton for South Fork coals, with exceptions where the coal is of admittedly superior quality. On certain of these specialties as high as $3.35 has been paid. Most of this tonnage has now been placed, however, or at least on as much as the operators think it prudent now to commit themselves, and for the next few weeks we are likely in this market to hear less of contracts and more of sales for limited periods of delivery. There is a lot of selling effort today to close business on a $2.95@3.10 basis, but buyers are not responding, even on the better grades. As a broad matter, the market in New England is simply not up to it, and purchasing is still on narrow and restricted lines.

On the other hand, the extreme anxiety of certain operators only tends to demoralize what market there is. New England buyers were accepting the statement that unless shippers could command their price they would keep the coal in the ground, when a fresh campaign was started to secure orders for prompt shipment. In Somerset and also in Cambria districts there has been a strong effort to induce early buying. Some weeks ago as low as $2.50 per gross ton was freely named on Quemahoning grades, and now $2.50@2.75 has been quoted on what have always been regarded as standard coals from the Wilmore Basin. Almost no tonnage will result from these efforts in New England, and it is rather a pity that buying sentiment here should be encouraged by this to await summer developments.

The movement here of Pocahontas and New River is extremely light. An attempt has been made to net $2.75 per net ton at the mines for both grades, but present indications are not hopeful. There are still accumulations at the Virginia terminals, and something of a tonnage has already been placed on the basis of $2.35 for Pocahontas. While barges and now and then a steamer in private hands can be chartered at $2 to Boston from Hampton Roads, yet these rates are only for single trips, and only the most loyal of customers are going to keep on paying a considerable premium for smokeless coals when Pennsylvania output is pressing for sale.

Bituminous prices at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net ton as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@$2.75	$2.80@$3.35
Philadelphia, gross tons	4.20@ 4.90	5.00@ 5.40
New York, gross tons	4.50@ 5.25	5.35@ 5.80
Alongside Boston (water coal), gross tons	6.10@ 6.85	6.90@ 7.65

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.70@5.25 f.o.b. Norfolk and Newport News, Va., for spot coal, the former Governmental differential of 35c. in favor of New River being fairly well maintained. Alongside Boston the present gross ton range would be $7.15@8.10.

Anthracite—The demand for domestic sizes continues light. Until the rates on railroad-owned barges are adjusted, or some kind of policy is made clear, there will probably be nothing like the usual spring shipments, at least for the present. Even all-rail, where there is no possibility of lower cost, the demand for domestic sizes is only transient. While certain of the retailers are trying hard to influence early buying on the part of the householder, there is an utter lack of snap and the public is not considering seriously all the material that is being handed out with regard to the great urgency of supplying the mines with orders thus early in the season. There is more coal in the bins of the ultimate consumer than is realized in some quarters, and there will have to be stronger inducements than are now offered to get the public to take its coal early.

There is only a scattered inquiry for coal by water, and then almost entirely in transportation that is privately owned and governed by market conditions. Coal in railroad barges is not being taken except in emergencies, and this is entirely due to the high rate that still prevails. A revision of the rate is momentarily expected, but as yet the trade cannot be certain it will be forthcoming.

NEW YORK

The new coal year finds trade in good condition and bright prospects ahead. Little coal moving because of harbor strike. Good demand for anthracite. Local consumers hesitate before ordering next winter's supply. Bituminous supplies short here, some pools reported as being empty. Shippers expect brisk business soon.

Anthracite—The start of the coal year 1919-1920 finds the industry in good condition, with bright prospects for a busy summer. Demand, while it has not been brisk locally, has been good in other nearby sections, and this has been reflected in operations at the mines. In this harbor not much coal has been moved for nearly five weeks because of the marine strike. Up to the present this has had little effect upon the local situation, as most dealers were well supplied and are now able to take care of orders by substituting one size for another when it is necessary.

Last week's blizzard, which was the worst snow storm (in fact the only snowfall) of any account here this year, caused a slight flurry in demand on the retail dealers, but they were able to take care of it without much trouble. Many of the local yards are nearly cleaned out of coal, while some have not got coal of all sizes.

The inability of shippers to get tows from the loading piers has enabled the local retail dealers to get rid of some of the immense stocks of the anthracite steam sizes which they took in conjunction with prepared coals last fall.

The trade looks forward to a heavy demand when the harbor labor troubles are ended. Dealers are expected to place heavy orders in order to replenish their stocks, and also to take advantage of the present mine prices, which according to previous announcement are to be increased 10c. per ton for five months beginning May 1. It is also expected that household consumers will begin to fill their bins for next winter just as soon as they realize that there will not be the usual spring reduction. They have been influenced in their desire to wait before placing their orders by the announcement that an investigation is to be made of the price situation.

There is a good demand for all-rail coal, and dealers in a position to get it are taking in a good supply. Salesmen say that conditions inland are brisk, and that unless production increases considerably from what it now is there will be a severe shortage before the summer is half over. The small production is due in most part to the lack of orders due to small consumption last winter.

There was a heavy decrease in dumpings at the New York Tidewater docks during the week ended Mar. 28, 986 cars having been dumped as compared with 1399 cars the previous week.

The demand for the steam coals continues active and there is no great surplus. The strike has had little effect upon the supply required by the trade in lower Manhattan, most of their coal being brought by wagons and trucks by ferry from Jersey City.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	5.85	7.70
Stove	6.10	7.95
Chestnut	6.20	8.05
Pea	4.80	6.55
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—A better demand and an improvement in harbor conditions have improved matters here. While it has not been possible to move coal from the docks with the same freedom as under normal conditions, consumers who have been in actual need have been able to get coal when they were willing to pay the additional cost of towing made necessary by strike conditions.

Public service corporations and steamships are now being taken care of without any trouble, due to the assistance given by Government agencies, but the bins of industrial concerns are nearly bare and manufacturers are becoming anxious. With the strike over shippers look for a heavy demand for coal which ought to be reflected at the mines.

Coal supplies at the docks are not large. Embargoes placed on shipments since the strike in the harbor began have kept receipts down to actual needs, with the result that it was said certain pools were without coal at the end of last week. A statement of the Tidewater Coal Exchange showed that on Mar. 26 there were 5729 cars of coal on hand in this harbor. There have been orders issued modifying previous orders, which will be the means of increasing supplies at the docks.

Wholesale dealers report many orders awaiting shipment. They say that with the labor trouble ended there will be a serious shortage of coal here. Loaded

boats are in good demand now, and some consumers are willing to pay fancy prices if deliveries can be made. Quotations on this class of business vary much, depending upon the towing distance. In some instances as high as $8.50 alongside is said to have been quoted for coal for steamships.

The trade is holding close to the late Government maximum prices for coal. There has been an improvement in contract business, and it is believed that a goodly percentage of the production for the next coal year has been signed up.

There was an improvement in dumpings of bituminous coal here during the week ended Mar. 28, reports showing 3012 cars dumped as compared with 1995 cars the previous week, an increase of 1017 cars.

Current quotations at the mine for various grades of bituminous coal for spot delivery and contract follow:

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.80 to 3.10	2.95 to 3.25
Clearfield County (good grades)	2.65 to 2.95	2.80 to 2.95
Reynoldsville	2.65 to 2.85	2.85 to 2.95
Quemahoning	2.85 to 3.10	2.95 to 3.10
Somerset County (best grades)	2.75 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.40 to 2.75	2.75 to 2.95
Western Maryland	2.50 to 2.75	2.65 to 2.85
Fairmont	2.10 to 2.35	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.35 to 2.40	2.35 to 2.60
Westmoreland ¾-in.	2.60 to 2.75	2.65 to 2.75
Westmoreland run-of-mine	2.40 to 2.65	2.40 to 2.65

PHILADELPHIA

Anthracite dullness increased by proposed price investigation. Little spring business offering. Some shifting of trade, both wholesale and retail. Retail price-cutting limited. Retailers do not fear investigation. Coal well prepared except pea. Steam coal contracts being made. Collections slowing up. Bituminous quiet. High-grade fuels scarce. Contracting chief activity.

Anthracite—Temporarily, at least, the spring business is in a sad state and much blame is placed on the publicity given in the daily papers to the proposed investigation of coal prices. While it appears to us that the best the public can hope for is an avoidance of increased rates, the dealers all report that most of their customers refuse to place orders because they apparently believe prices will be lowered at least 50c. a ton. We even hear of dealers offering to protect prospective buyers in the event of a reduction, but so far this offer has met with little success in getting business.

After numerous interviews we are firmly convinced that prices will advance on May 1 as per schedule and a large majority of the dealers are satisfied they will; but the fact stands out that the demand is light. Unless something happens to straighten out the market and cause the public, and then the dealers, to buy coal substantially for at least three months, there is surely trouble ahead.

Some houses report making sales to new customers and missing the orders of some of their old trade. This is an echo of the trials of 1917, when many dealers thought they would have fared better had they been doing business with another house. The retailers also notice considerable shifting of trade. No doubt they all have a number of dissatisfied customers, and they will all lose some and gain others.

One surprising feature of the trade is the comparative firmness of the retail prices. Except in the northeastern section of the city, where several dealers have made substantial reductions from the general prices, we can learn of no price-cutting.

A number of dealers in referring to the proposed investigation which it is reported may cause their margin of profit to be looked into, state that any lowering of their prices that might be forced upon them would necessarily be made possible only by reducing wages. Labor is not scarce, but it is a fact that few dealers have taken advantage of it by cutting wages. Necessarily they are employing fewer men and it appears to be the policy to lay them off when not needed rather than to ask them to work for lower pay. Any number of dealers express their willingness to throw open their books to any Governmental or State investigators.

It has been a long while since such well prepared coal has come to this market. The improvement is general and very noticeable. All shippers seem to realize that under present conditions it would be impossible to hold their trade with coal of a poor standard of preparation. Most of the coal coming here now is well above the standard set by the big shippers. If there is an exception it is pea coal. Operators do not seem to see the necessity, or at least the advantage, of improving this size. Many dealers have on hand a supply of pea coal which was shipped during the winter. They hesitate to deliver in more than one-ton lots because it is small and poorly prepared. They have been buying a few cars to deliver on the spring orders, but report little improvement as to size. This complaint is general. The coal may be cleaner and contain less buckwheat than during the past year, but it is still too small. A number of individuals are offering this size at less than circular rate, and all shippers are having trouble in disposing of their production. Stove and nut still have the call, with egg in fair demand.

The market on steam sizes is quiet. Buckwheat at $2.75 is being freely offered by some individual shippers. The big companies continue to ask and get $3.40 for this size. The companies are also doing considerable contracting on the steam sizes, but it is noticeable that on contracts covering a year's supply from Apr. 1 some are at least inserting a clause protecting the buyer in case of any reduction in the miners' wages. This is true of their contracts for all steam sizes. One big company we know of is actually not inserting any price, but simply guaranteeing to ship a specified tonnage during the year at the price in effect at time of shipment, which at this time is $3.40 for buckwheat.

Some shippers report a greater proportionate demand for rice than for buckwheat, but sales are being recorded at $2.40 to $2.50. Barley has been quoted low, and we have heard of it being offered at $1.25, but this is probably river coal, or some other low grade material.

Collections are dragging and it is believed that in their anxiety to secure business the shippers have recently become quite lenient with many old customers.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	5.85	7.70	Rice	2.75	3.65
Stove	6.10	7.95	Boiler	2.50	3.50
Nut	6.20	8.05	Barley	2.25	3.15
Pea	4.80	6.40			

Bituminous—Production continues to be low due to the continued lack of demand. The trade continues to mark time until such a time as present stocks are greatly reduced and there is something of a resumption of industrial activity in this district. Producers and middle houses are spending most of their energy now on making contracts, and fair business is reported in this direction. At present there is something of a scarcity of high-grade coals, as the larger share of limited production is being placed on contracts. Prices continue their display of firmness, with price range fairly represented by the following:

Georges Creek Big Vein	$3.10 @ $3.25
South Fork Miller Vein	3.00 @ 3.20
Clearfield (ordinary)	2.65 @ 3.90
Somerset (ordinary)	2.55 @ 2.80
Fairmont	2.00 @ 2.35

BALTIMORE

Contracting for new year slow, as consumers remain in open market for light purchasing. Coal men warn that now is low period and Government officials talk of impending shortage, but to little effect. Prices on immediate sales off color. Hard coal men still undecided here.

Bituminous—With the Government fuel experts talking of shortage of coal in the months to come unless business men awaken to the fact that orders should be placed for coal at once in order to assure early production of a greatly increased nature, and with mine operators showing confidence in the future by refusing to contract at prices below the old Government figures for better grade coals, there is still a very flat immediate market.

Considerable coal caught awheel is sold at prices running all the way from $2 to $2.50 mine basis for good grade. Coal is being shipped from mines for immediate use at prices ranging from $2.25 up to $2.65 or $2.75; and yet the same coals are refused on contract for future delivery at prices below the Government maximums of the past of $2.75 and $2.95.

The immediate sales are undoubtedly due to the fact that a number of mines find that they now have but one or two days of work on hand and can not maintain organization and hold mining forces with less than a three-day-per-week operation. In the effort to spur production to such a point some operators are offering the cut prices. Meanwhile, despite the warnings of well posted fuel men, the consuming public is far behind the ordinary spring schedule for getting under cover.

In relation to the growing bunker business here Mayor Preston has received an interesting communication from H. M. Hitchcock, assistant director of operations of the Emergency Fleet Corporation, to the effect that this city may shortly be greatly increased in importance as to the handling of both coal and oil for bunker purposes.

Anthracite—The end of the past week saw the retail hard coal situation here still somewhat undecided. While independent operators for the most part have indicated that they will follow the company reduced coal price schedule and the 10c. per month advance thereon after May 1, there is a strong feeling here that some coal off that schedule is likely to be offering from mines that wish to continue operation. The local retailers have talked over the situation pretty thoroughly but have found some phases of it rather uncertain. The result has been that no definite announcement as to a spring retail schedule for Baltimore is as yet forthcoming.

Lake Markets

PITTSBURGH

Production still light. Inequality of Government prices still mentioned. Some demand for gas coal. Prices fairly well maintained.

The local coal market has not improved. Whatever help might be rendered the situation by the further depletion of stock piles has been equalized by lower rate of coal consumption, both for manufacturing purposes and as domestic fuel. There has been hardly any demand for domestic coal, and so little, indeed, as to prevent a clear-cut market price from being disclosed.

Production in the Pittsburgh district is at between 25 and 30 per cent. of capacity, as has been the case for several weeks past. A number of mines are closed entirely, but the restriction in most cases is by operating mines short time. Labor seems to be fairly content with the amount of employment it has received. Labor leaders are understood to be assiduous in pointing out to the men that decreased production is essential for the maintenance of prices, and in turn of wages.

Pittsburgh district coal operators still refer to what they consider the great inequality in some of the Government coal prices, claiming that relative to cost of production the Pittsburgh district was given about the lowest coal price of all. The aftermath, they point out, is that when the coal market in one district or another declines from the old Government level the Pittsburgh district market is expected to decline likewise, whereas it is not in position to do so.

Relatively speaking, there is a much better demand for gas coal than for steam coal. While there is little demand for steam coal there is still less for domestic. Odd lots of coal loaded on track and requiring to be moved frequently go at ridiculous prices, which are not considered in quoting the market. The large operators are holding quite stiffly to regular prices, but smaller operators frequently shade 10c. or 15c., and the market is thus quotable as follows: Steam coal—Slack, $2@2.10; mine-run, $2.25@2.35; domestic, 1¼-in., $2.25@2.35. Gas—Slack, $2.25@2.35; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.75, per net ton at mine, Pittsburgh district.

TORONTO

Trade continues very quiet. Ample stocks on hand. Consumers withholding orders in hope of lower prices.

Conditions in the coal trade are unchanged, business being unusually quiet for the season and dealers have large stocks on hand. The demand as a rule is limited to present requirements as consumers in many cases are postponing orders in the hope of a reduction in prices. Dealers state that there is not the slightest reason to expect any drop in prices and that any change later in the season is more likely to be an advance. Prices are generally well maintained with occasional slight shading in the wholesale rates.

Quotations for short tons are as follows:

Retail:

Anthracite egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	8.25
Slack	7.25
Domestic lump	10.00
Cannel	13.00

Wholesale f.o.b. cars at destination:

Three-quarter lump	6.25
Slack	5.25

BUFFALO

Trade improvement slight. General business hanging off. Jobbers uneasy over Government action. Anthracite slightly more active. Loading lake vessels.

Bituminous—Some slight improvement is reported by certain members of the trade, but conditions in general are not so good. The jobber is reducing his supply, but is not ready to buy liberally. As a rule he is still waiting for prices to come down, though he has been disappointed for the most part so far. Coal offered at a reduction is likely to be of poor quality, so a seeming decline may not mean anything. Jobbers are not pleased over the move to bring the operators and the Government closer together, and some say it is a direct blow to them. It will take time to decide that point.

Some Allegheny Valley prices are coming down to the Pittsburgh, but the rule is to hold to the old Government price of $4.65 for thin vein, all sizes, with $4.45 for Pittsburgh and No. 8 lump, $4.20 for same mine run and slack, $5.65 for smithing and smokeless, and $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The demand has increased. Consumers are beginning to buy for winter supply, but the actual consumption is small as the weather has continued warm and the rule is to go back to natural gas since the restriction is off. The complaint of much impurity, especially slate, in the coal continues and it is hoped that the legislature will pass the bill forbidding it.

Most of the activity in the harbor is due to the loading of lake vessels with anthracite, more than 150,000 tons now being afloat. There is not much demand from the upper lake ports, as a surplus of considerable extent will be on hand there on May 1. Some of the smaller ports have asked for coal, but as a rule the vessels have been taken only for the head of the lakes, where there is cargo to bring back.

The lake rates for leading ports have been fixed at 42½c. to Lake Superior, 50c. to South Chicago and Milwaukee, and 60c. to Chicago. This is a reduction of about 5c. from last season. The minor ports will pay 10 or 15c. over the larger ones.

CLEVELAND

Conditions in all local coal markets, except domestic, are slightly improved. Efforts to move steam coal not bearing much fruit. Coarser grades decidedly stronger. Coal rates to head of Great Lakes for 1919 reduced. Lake trade now can be on in full swing.

Bituminous—The increasing flow of bituminous to Lake Erie ports for loading for the head of the Great Lakes is stirring the local steam-coal market somewhat, but the effect is not marked. Steam-coal users so far have not proved responsive to efforts of operators and the Fuel Administration to renew buying. Hope, however, is held out that the agreement on iron and steel prices will stimulate business, iron and steel interests being the leading steam-coal users in northern Ohio.

Meanwhile, with users still determined to clean out their stockpiles before reëntering the market, prices are decidedly firmer. Conviction is growing that not only will present prices hold, but that coal will be decidedly scarce later in the summer when the lake trade gets into full swing, present stockplies are exhausted and steam-coal users contemplate their winter supply. Purchasing by the railroads, too, is a factor that is looming large. It is understood that the administration has been anxious to place contracts with No. 8 operators, but the operators have delayed negotiations until the trend of Secretary Redfield's price-stabilizing program can be definitely ascertained. Between 30 and 40 per cent. of No. 8 coal produced becomes railroad fuel, a percentage big enough to swing prices on the rest of the market.

While a great many No. 8 district mines have not yet felt the stimulus of the opening of the lake trade and continue on a 25 to 30 per cent. basis, the majority have increased their operating percentage. Navigation on the Great Lakes will not open in earnest until about Apr. 10, so two more weeks of comparative idleness may be looked for. A growing feeling of unrest is apparent among the mine workers and operators are anxious to get them busy, believing this is to be the best cure for the radicalism that is seeping through eastern and southern Ohio coal-mining districts.

The domestic bituminous trade, along with the anthracite one, continues slow. Mine-run and lump Pocahontas are more difficult to get than a few weeks ago, but dealers still are quoting $7.20 for the former and $7.50 for the latter, net ton delivered. Anthracite demand has fallen to an almost negligible factor.

Lake Trade—A fair-sized block of coal has been covered by a local interest for 42½c. a ton to the head of the lakes, 50c. to Milwaukee and South Chicago and 60c. to the Chicago River. These rates, which are the 1917 ones revived, compare with 48c. to the head of the lakes and 50c. to Lake Michigan in the 1918 season. It is expected that these rates will be accepted all around and will prove the prevailing 1919 ones.

Considerable coal is moving toward the lakes, and probably 20 cargoes have been loaded; but the season has not yet been actually opened. Great Lakes vessel interests are not anxious to repeat last spring's performance, when the season was rushed and thousands of dollars were necessitated by repairs for ice damage, while stocks on upper lake docks still are ample. It still looks as though the season will be quite slow in getting under way.

Coal prices per net ton delivered are as follows:

Anthracite:	
Egg	$10.80 @ 10.95
Chestnut	11.00 @ 11.10
Pocahontas:	
Lump	7.50
Mine-run	7.20
Domestic Bituminous:	
West Virginia splint	7.05 @ 7.15
No. 8 Pittsburgh	6.15 @ 6.35
Massillon lump	6.95 @ 7.10
Steam coal:	
No. 6 slack	4.45 @ 4.55
No. 8 slack	4.90 @ 4.95
Youghiogheny	4.95 @ 5.05
No. 6 mine-run	4.45 @ 4.55
No. 8 mine-run	4.90 @ 4.95
No. 8, ¾-in.	5.50 @ 5.60

DETROIT

With buyers in the steam and domestic branches of the bituminous trade maintaining an attitude of indifference, Detroit jobbers are doing little business.

Bituminous—Dullness is a distinctive feature of the bituminous coal trade in Detroit. In contrast with the period before the war, orders are infrequent and of small proportions. To piece out stocks and obtain coal in a form called for by their customers, some of the retailers are said to be placing small orders for domestic lump, with the proviso that delivery must be immediate. By getting the coal at once, these buyers expect to be able to distribute it before the cold weather passes, thus avoiding adding to the excessive stocks, which most of the leading dealers will be obliged to carry into the summer. These stocks usually consist of fine coal in a variety of sizes and include considerable low grade coal and are proving difficult to reduce.

The large proportion of inferior stock in the reserve piles of steam plants also is discouraging additions to reserves. Users of steam coal want to get the undesirable coal out of the way. The magnitude of their stock piles and the diminished activity of their plants since ending war work prolong the time that must elapse before many of the buyers will be in position to enter the market.

Though there is said to be little coal on tracks due to the caution of jobbers in restricting orders to the quantity for which they have buyers, much difficulty is being experienced in selling slack and mine run. In the case of the former, prices are reported to have been quoted as much as $1 below the Fuel Administration scale. Domestic lump is firmer and prices are said to be holding at the Government basis.

Anthracite—Because of lower temperatures, there has been a slight improvement in demand for anthracite among domestic consumers recently. There seems to be sufficient coal of all domestic sizes available to meet the demand. Some retailers are warning their customers of a prospective advance in price Apr. 1, reflecting the advance announced by producers. The supply of domestic coke also seems plentiful and numerous domestic buyers are utilizing the opportunity to substitute coke or anthracite for the proportion of bituminous coal, ordered by the fuel administration.

COLUMBUS

A better feeling is shown in the coal trade, especially in steam circles. Buying is still limited to actual needs and little contracting is reported. The price question on contracts is still unsettled. Considerable cutting on spot shipments is reported.

The coal trade in Ohio is becoming more active, and the tone of the trade is steadily improving. Although business is rather slow in getting on a peace basis, still the coal trade is becoming better and producers as well as shippers are more encouraged. The pessimism of the past few months is gradually passing away, and coal men generally are preparing for a more active demand.

The steam business is still slow, as is inevitable under the circumstances. Reserve stocks are still large, and with consumption cut to a rather low point, purchasers are slow in entering the market. Iron and steel plants are in a better shape now, and orders from this source are expected within the coming few months. Rubber factories are still well stocked with fuel. Railroads are taking only a fair tonnage as the freight movement is somewhat restricted. Some of the war industries are being placed on a peace basis, and this presages a better fuel demand. On the whole the tone of the steam trade is better and more buying is expected soon.

Contracting is still unsettled. Quite a few contracts expire around Apr. 1, but so far few have been renewed. Prices are not fixed, and as a result the purchaser is holding off. The ability to buy sufficient fuel for current needs on the open market, often at reduced prices, does not bring contracting any nearer completion. Some few contracts at only a slight reduction from the last Government price have been reported.

The domestic trade is slow. Retail stocks are apparently sufficient for the present, and dealers are loath to buy under existing circumstances. There is a fair demand for the fancy grades such as Pocahontas and West Virginia splints. Hocking and Pomeroy grades are not selling well. In fact, retail stocks are in such shape that little demand from that source is expected within the coming few months. Retail prices are still fairly well maintained, although some of the dealers are cutting in order to move stocks.

CINCINNATI

Slightly improved demand is noted, especially in smokeless coal for contract. Little change is general conditions, and spot market is overloaded and weak.

While there has been virtually no change in the fundamental conditions governing the Cincinnati market during the past week, there is a more optimistic tone to the reports of leading producers and jobbers, as they state that contract demand for the better grades of coal, especially smokeless, is satisfactory, and that prices are not governed by the present surplus of fuel on the market. Demand is not heavy, but what contracts are being closed are closed under satisfactory conditions.

It is in the bituminous department of the market that the most unsatisfactory state of affairs exists, due to an oversupply of coal and an almost entire absence of demand, bringing about a weakness which will hardly disappear until there is more of an equilibrium between supply and demand.

Industrial conditions, in this section at least, are regarded by the coal trade as good, as there have been no extensive shutdowns among the factories, and employment is still general, there being comparatively few men out of work. Consumption of coal, however, appears to be at the minimum; and retail dealers are not in the market to any extent, as their customers are as a rule carrying some coal over, and there is now virtually no domestic consumption, as the weather for the past week or more has been so warm as to require no heating, either in homes or factories. The buying by retailers is consequently confined to those who can reasonably anticipate a considerable business, and who therefore are willing to protect themselves by securing moderate supplies of coal under present conditions.

LOUISVILLE

Eastern Kentucky operators meeting with slightly better demand, with conditions duller in western Kentucky fields.

Such demand as there is for coal at the present time is largely for high grades. Considering the close margin existing between eastern and western Kentucky fuel, the former is managing to get the business. Eastern Kentucky as a whole is running 50 to 60 per cent. of full-time ca-

pacity, whereas western Kentucky is hardly working two full days a week at the present time, not being able to secure business on either domestic or steam sizes. The differential existing between the higher-grade eastern Kentucky coals and the western Kentucky grades is not sufficient at this time to create a demand for the lower grades, resulting in dull business, as the western Kentucky operators are holding prices firmly.

The demand for domestic coal is lightening up somewhat, but steam is slightly better, as many industrial consumers are now running a little low, and are working out their stocks. The Lake movement should start soon, and is expected to take care of a fair volume of business.

Jobbers report that retail stocks as a whole are low, and that a fair business is being handled on immediate delivery basis. Retailers claim that business is dull as a whole, and that they can see little encouragement unless sufficient publicity is given to the production situation to force a stocking demand during the spring and summer months.

On a short-ton basis the Kentucky market is about as follows:

	Eastern Kentucky	Western Kentucky
Block and egg	$2.85@$3.00	$2.60
Run-of-mine	2.20@ 2.40	2.35
Nut and slack	1.90@ 2.00	2.05

Some eastern Kentucky operators are selling no block or egg for less than $3 and are getting $2.60 for mine-run. Others are getting as high as $2.10 for nut and slack. However, some nut and slack is selling at as low as $1.85, and some run-of-mine is quoted at as low as $2, where operators are anxious to dispose of spot coal.

Western Kentucky prices are fairly firm, but some immediate delivery nut and slack is selling at as low as $1.85, with 15 to 20c. cuts on other grades. The western Kentucky market as a whole is fairly firm, however.

BIRMINGHAM

Domestic trade improves as dealers begin to contract for next winter's supply. Steam situation without material change. Mines operating on reduced schedules hold production in the range of requirements. Prices remain stable.

Dealers in domestic coal are beginning to evince an interest in the market, and the number of contracts made during the past week is believed to mark the start of a buying movement which will hold up well through the spring and summer months. Sales agency officials express the opinion that dealers who neglect to provide for their year's requirements within the next few weeks will find difficulty in securing the coal needed later on—especially the higher grades, the production of which is always far below the requirements of the trade. The supply of the better and also the medium grades is hardly adequate to the needs at this time. Prices are as follows per net ton, mines:

	Lump and Nut
Black Creek and Cahaba	$3.85
Corona	3.40
Carbon Hill	3.15
Montevallo	5.00

Steam continues easy and the local market was not featured by any large deals during the past week. Small orders and contract business in hand have about absorbed the daily production. Quotations are on basis of the last Government schedule, prices being as follows per net ton mines:

	Mine-Run	Prepared	Screenings
Big Seam	$2.45	$2.75	$2.40
Black Creek and Cahaba	3.45	3.75	3.05
Corona, Pratt	2.85	3.05	2.45

Coke

CONNELLSVILLE

April adjustments under consideration. Narrow prompt market. Prices unchanged. Production still decreasing.

Adjustments have not been completed as to prices to be paid for shipments in April against furnace coke contracts that call for monthly negotiation when there is no Government price to control. Some of these contracts were adjusted at $4.50 for March, but the great majority were at $4.25, and it is possible that some adjustments were at still less. Operators speak now of desiring a $4.50 adjustment for April, but the probability is that they will be content with $4.25.

A difficulty in the situation as to adjustments is that there is no well defined spot or prompt market to furnish a basis for contract adjustment. There are offerings at all sorts of prices, but very little buying. Some of these offerings are at less than $4, but they are regarded as of inferior grade in any event, while the total tonnage is not sufficient to make the market. At $4 the few furnaces that have any occasion to buy prompt lots have been able to get all they needed, and this is commonly regarded as the market, though it is contended that no large quantities could be picked up at the figure.

Coke production continues to decline, but hardly keeps pace with the declining consumption, as every now and then another blast furnace goes out. Some of the by-product operations attached to steel works furnaces have had to curtail output. These operations would be glad to sell coke in the open market, but tonnages called for are so small that it is not worth while making the effort to sell, and Connellsville coke continues to make what little market there is.

Foundry coke is unchanged, there being fair brands available for prompt shipment at $4.50, while a few of the old line operators, with contracts to protect, still quote $6.

The market for spot and prompt is quotable at $4 for furnace grade of standard quality and at $4.50@6 for foundry coke, depending on brand, per net ton at ovens, Connellsville region.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Mar. 22 at 187,806 tons, a decrease of 14,502 tons.

Buffalo—The season still drags, on account of the failure of iron ore to move. The lake fleet might have been active all winter, but instead of pushing out early there is no disposition to move as yet. Even the coal loaded is to move at the option of the vessel, and it may be here a month longer. Quotations on coke remain at $7.60 for foundry, $6.60 for furnace and $6.10 for off grades, the last price being quite unsteady, with fuel coke much of a drug on the market. All prices are f.o.b. Buffalo.

Middle Western

GENERAL REVIEW

Market conditions improving. Operators not eager to close contracts, though inquiries are brisk. Railroad coal question. Prices being maintained.

There has been but little change in the coal market during the past week. There is no denying that market conditions are now a little better than they were a week or so back. The current demand for coal continues dull in the extreme, but considerable interest is now being taken by the public in coal contracts. Strange to say, the larger and better informed of the operators are not falling over themselves in eagerness to obtain contracts, and absolutely no concessions are being made in regard to price.

The reason for this interest on the part of the coal-buying public in contracts is that the labor situation in most of our important coal-producing fields is anything but satisfactory. If labor troubles occur in any of the fields, it will have a tendency to raise sharply the current prices in the coal-producing districts not affected, and those purchasing agents not protected by contracts will have to meet this advance in price if they wish coal. There is still a big amount of coal in storage in this territory, and while this tonnage is enough to affect a weak market, it is not great enough to be of much help in case of prolonged labor difficulties.

Another factor which may have some bearing on the contract question is that general manufacturing and industrial conditions appear to be more stabilized. More confidence all along the line is being felt. Industries that were practically at a standstill two or three weeks ago are now fairly active, although but few are running full time.

The question of railroad coal appears to be progressing satisfactorily, and it is believed that this matter will be settled on a permanent basis by the end of April. This item alone is enough to give the market a stronger tone than it has had for some time. The railroads consume more coal than any other industry, and this market assured to the operators cannot but give a better feeling of confidence to the entire coal industry.

Coal is moving more freely at this writing than it has for a long time. Reports come in that Minnesota, Iowa, Wisconsin, Illinois and Michigan are buying coal in more liberal quantities than heretofore. Operators in southern Illinois say that there has been some improvement in running time during the past week.

Prices for high-grade Southern Illinois coals continue firm. The Springfield district continues to run about the same, with prices holding up fairly well. There has been no shading of prices on coal from the better known central Illinois mines. When the question of railroad fuel is settled, there will be a big improvement in running time for the whole central field. In Indiana, especially in the Fourth vein district, and also Knox County, conditions are better than they have been for some time. Practically all mines are reporting better running time, more demand for coal and consequently less price-cutting; in fact, no price-cutting on the part of the larger operators.

CHICAGO

Some large steam contracts reported. Domestic situation fairly good.

The Chicago steam market shows no signs of any radical change, although some large contracts were reported. The current market continues fairly dull, although there is some improvement due to renewed industrial activities. The only news of importance is that the bids for the city business were opened, and proved a great surprise, both to the trade in general and the city fathers in particular. It was found that the bids were considerably under what the city was prepared to pay for its coal. This situation is not without a lesson to some of our best Chicago dealers.

The domestic situation is fairly good. There is a demand for high-grade domestic fuels, which will probably keep up for another month.

Prices per ton are as follows:

	F.o.b. Mines	Rate to Chicago
ILLINOIS		
Southern Illinois		
Franklin, Saline and Williamson Counties, etc.		
Prepared sizes	$2.55@$2.75	$1.55
Mine-run	2.35@ 2.50	1.55
Screenings	1.85@ 2.20	1.55
Central Illinois		
Springfield District		
Prepared sizes	$2.55@$2.75	1.32
Mine-run	2.35	1.32
Screenings	2.05	1.32
Northern Illinois		
Prepared sizes	$3.25	1.24
Mine-run	3.00	1.24
Screenings	2.75	1.24
INDIANA		
Clinton 4th Vein District		
Prepared sizes	$2.65@$2.75	1.27
Mine-run	2.35@ 2.45	1.27
Screenings	2.05@ 2.25	1.27
Knox County Field		
Prepared sizes	$2.65@$2.75	1.37
Mine-run	2.35@ 2.45	1.37
Screenings	2.05@ 2.25	1.37

MILWAUKEE

Continued dullness marks the coal market, but prices are well sustained. Yards well supplied with all grades.

Nothing has occurred to break the monotony of the coal situation at Milwaukee. The demand is light all around, and it must continue to grow lighter with each passing day, as the season is too far advanced to admit of anything like zero weather. Prices are firmly held, however, and there will be no change in this respect until the beginning of the new coal year in May. Illinois coal is selling in that state from 60 to 90c. per ton lower than last year, according to reports, but until somebody here runs out of coal and buys at the new rates, they will have no effect here.

Pocahontas coal, which was practically out of the market during the last year of the war, is again taking its place. All sizes and mine-run can now be readily secured. Anthracite is coming by rail daily.

Motor trucks are fast succeeding horses in the delivery of coal in Milwaukee. The Milwaukee-Western Fuel Co., the largest coal firm in the city, and the Gross Coal Co., are selling out their horses, wagons and kindred equipment and will rely upon motor vehicles entirely in future.

ST. LOUIS

Warm weather and a quiet market, with nothing to indicate change. An abundance of all kinds of coal. Domestic demand entirely off and steam demand light, with a little storage call here and there.

Domestic tonnage has practically fallen off altogether and there have been a few scattered orders for storage coal. General

conditions in the Illinois field are unsatisfactory, both to the miners and the operators, and it is evident that a readjustment must take place. The miner appears confident of his ability to get anything that he may ask for, and some of these demands are so unreasonable that the operator will not even listen. On the other hand, the operators have some grievances that need readjusting, judging from reports, and it may be to mutual advantage if both sides get together to straighten these matters out so that when work does resume the industry will be on a more equitable and stable basis.

In the Standard field conditions are unusually bad. The demand for this coal seems to have fallen off almost entirely, except for a little steam. Some railroads are not picking up any storage coal, but their local requirements seem to be unusually light. The northern roads are not taking the tonnage now they did in previous months, and all along the line there is a slowing up. This, added to the dropping off of domestic business, has put some mining communities in a serious plight. There is much dissatisfaction over the one day a week some miners are getting, and others no work at all, while in some places the mines are working three and four days. The men seem to think this tonnage should be divided equally among all operations.

Up to Mar. 28, Standard screenings were selling at around $1.50, 2-in. lump from $1.75 to $2, 6-in. lump from $1.75 to $2.25, egg from $1.70 to $1.90, and mine-run about $1.65 to $1.75. Effective Apr. 1 the prices were increased.

In the Mt. Olive field conditions are somewhat improved. There is little demand for Mt. Olive coal in this market, but a fairly good tonnage seems to move north. The railroad tonnage seems to hold up fairly well in this field, but working conditions are poor, almost as bad as in the Standard field. However, prices are being fairly well maintained.

In the Williamson and Franklin County field, and also in Du Quoin, there is a slowing up in business that has caused some uneasiness among the operators. As a whole, however, conditions are all that could be expected, and there is every reason to be optimistic that this field will be able to maintain its prices and at the same time provide enough tonnage to keep both the miners and the operators satisfied.

The railroad tonnage continues fairly good, but the movement on some roads is not all that could be desired. This is chiefly on account of the large number of unbilled loads that have congested the sidings in this district.

Nearly all mines that are running are getting two and three days a week and some more, but several mines are shut down entirely. The independents are still selling coal below the circular, which the association members manage to maintain. Steam sizes are heavy in this field and domestic fairly active.

In the St. Louis market proper there is little demand for anything. Anthracite is coming in, but there is little moving, and smokeless has as yet failed to make any impression.

The new coke prices to the domestic consumer in St. Louis, as announced by the M. W. Warren Coke Co., which handles the output of the gashouses and the by-product plant here, will be $9.50 on by-product and $7.75 on gashouse. The retailer will get $2.75 gross margin on these prices. These prices are f.o.b. the retailers' tracks, and the same prices will prevail at the retorts.

The circular at the present time f.o.b. the mines is:

Williamson and Franklin County Association:		Mt. Olive and Staunton		Standard	
Lump, egg and nut	$2.75	....		....	
Washed Nos. 1 and 2 nut	2.85	....		....	
Independent:					
Lump, egg and nut	2.55	2.55	Lump and egg	2.25	
Washed Nos. 1 and 2 nut	2.85	....	2x3 nut	2.00	
Mine-run	2.35	2.20		2.00	
Screenings	2.20	2.05		1.75	
3-in. lump	....	2.30		....	
2-in. lump	....	....		2.15	
2x6 egg	....	....		2.10	

Williamson-Franklin rate to St. Louis is $1.07½; other rates $0.92½.

I. C. C. Decisions

No. 9005—Rapson Coal Mining Co. vs. Colorado & Southern Railway Co. et al. Submitted Nov. 25, 1918. Decided Jan. 27, 1919.

1. Rates on bituminous nut coal, in carloads, from Rapson, Colo., to certain destinations in Oklahoma and Kansas found to have been and to be unreasonable. Reasonable maximum rate prescribed and reparation awarded.

2. Record does not warrant establishment of joint rate over route of movement.

No. 9006—Cabin Creek Consolidated Coal Co. et al. vs. Cincinnati, Hamilton & Dayton Railway Co. et al. Submitted Oct. 5, 1918. Decided Feb. 13, 1919.

Defendants' demurrage rules applicable in 1915 and 1916 on shipments of lake cargo coal held at ports on Lake Erie, awaiting transshipment by water, not shown to have been unreasonable or unduly prejudicial. Complaint dismissed.

No. 9667. Ohio Valley Coal Operators' Association vs. Louisville & Nashville Railroad Co., et al. Submitted Jan. 13, 1919. Decided Feb. 13, 1919.

Upon complaint attacking as unreasonable and unduly prejudicial the rates on bituminous coal in carloads from mines in western Kentucky on the Louisville & Nashville R.R. and Illinois Central R.R. to points in Ohio, Indiana and Michigan, and seeking the establishment of joint rates to the territory north of the Ohio River, Held; That the rates from mines in western Kentucky on the Louisville & Nashville R.R. to Cincinnati, Ohio, are and for the future will be unduly prejudicial to the extent they exceed or may exceed the rates from mines on the Louisville & Nashville R.R. in the Jellico-Middlesboro group in eastern Kentucky and Tennessee by more than 15c. per net ton; and that otherwise the prices complained of are not shown to violate the act.

General Statistics

ANTHRACITE PRICES SLOWEST TO RISE

Anthracite continues to hold the position of having shown the smallest increase in price, during the war period, of 51 commodities in general use. This is the finding of the Bureau of Labor Statistics, United States Department of Labor, set forth in the December issue of the *Monthly Labor Review*, Vol. 7, No. 6, pages 111-113. The 51 commodities include foodstuffs, textiles, leather and mineral and metal products.

According to the Government figures, which are based on wholesale prices carried up to Nov. 1, 1918, Pennsylvania anthracite has advanced only 31.80 per cent. over the price quoted in 1913, which in every case is taken as a base. Many other products doubled or even trebled. Taking the 1913 quotations as 100, prices of various staple commodities as given by this Government publication are:

Anthracite	131.80	Creamery butter	178.70
Gasoline	145.80	Granulated sugar	204.70
Copper wire	173.70	Milk	234.00
Furnace coke	236.40	Fresh eggs	219.90
Cotton, middling	253.90	Bacon	225.20
Bleached muslin, Lonsdale	304.90	Lard	241.80
		Fresh beef	188.50
Women's shoes	223.00	Scoured wool	305.10
Flour	222.70	Rye flour	264.40
Corn meal	210.80	Oak sole leather	171.50
Potatoes	161.70	Wool storm serge	291.70

In actual figures, some of the changes are: Anthracite, nut size, which was sold wholesale in 1913 for $5.318, is now given as $7 per gross ton. Gasoline, worth 16.80c. in 1913, is reported as 24.50c. Good standarde patent wheat flour, sold at $4.584 a barrel in 1913, was replaced by standard war flour at $10.210 a barrel. Granulated sugar worth 4.30c. a pound in 1913 is now held at 8.80c., and women's shoes, wholesaling at $2.175 just a little more than five years ago, are now quoted at $4.850 a pair. In the same way fresh eggs leaped from 22.60c. to 49.70c., creamery butter from 31c. to 55.40c., and fresh beef from 13c. to 24.50c. Storm serge worth 56.30c. a yard in 1913 is now quoted at $1.642.

HAMPTON ROADS TONNAGE IN JANUARY

Norfolk & Western Ry.	491,344 Tons
Virginian Ry.	305,996 Tons
Chesapeake & Ohio	272,152 Tons
Total	1,069,492 Tons

BALTIMORE & OHIO COAL TONNAGE IN FEBRUARY

The following is a statement of the coal and coke tonnage moved over the Baltimore & Ohio system and affiliated lines during the month of February, 1919, as compared with the corresponding month of the previous year:

	Tons, 1919	Tons, 1918
Coal	2,293,179	3,225,974
Coke	125,210	225,258
Total	2,418,389	3,451,232

NORFOLK & WESTERN TONNAGE IN FEBRUARY

Below is given a statement of the coal tonnage from mines on the Norfolk & Western R.R. and from other railroads, for the month of February, 1919:

From:	Net Tons
Pocahontas field	1,085,829
Tug River field	200,124
Thacker field	146,105
Kenova field	52,444
Clinch Valley field	71,037
Other Northern and Western fields	3,410
Total Northern and Western fields	1,558,949
Williamson & Pond Creek R.R.	94,929
Tug River & Kentucky R.R.	51,535
All other railroads	63,160
Grand total	1,768,573

COAL AGE

Volume 15 New York, April 10, 1919 *Number* 15

America's Opportunity in Foreign Markets

By Floyd W. Parsons

NLY a man of super-courage would dare commit himself today as to just what are normal prices and normal business conditions. Industrial activity in America at the close of the war had reached a peak never before touched. Even recessions that have occurred since the signing of the armistice have not brought most lines of trade back to the volume sustained in pre-war days.

Nothing but experience will determine what level of prices is in keeping with current happenings. Old standards no longer rule. Labor has secured new power and wage reductions are being opposed successfully. The money of all nations has been inflated as never before. Pre-war scales no longer are precedents on which it is safe to base calculations.

Out of all the confusion, however, it is possible to discover a few guide-posts. Merchandise shipments from the United States during the first quarter of this year are approximately $1,750,000,000. Imports were less than $700,000,000, so that the balance of trade in our favor for January, February and March is more than a billion dollars. Since January, 1916, the trade balance in our favor totals nearly eleven billion dollars. No such record was ever attained by any nation before.

What the foregoing statement really means becomes more apparent when we say that during the thirty years preceding 1914 the favorable trade balance of the United States was not so large as this balance of the last thirty-nine months.

Such a one-sided volume of foreign trade cannot continue forever. If it did, we would soon find that we were expending our resources and our effort to no real advantage. Soon our customers on the other side of the Atlantic would be without funds to meet our bills, and the bottom of the business would drop out.

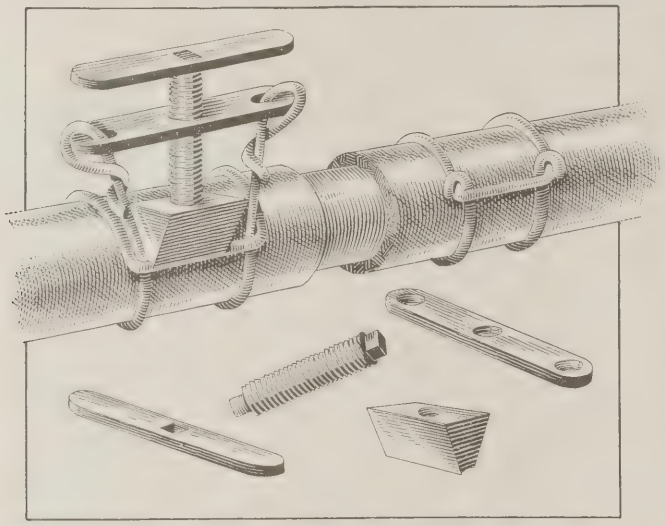
We have an advantage in foreign trade, and it is necessary that we hold it. Our continued success depends on the manner in which we finance future exports. Everyone knows that the man who buys must pay. Foreigners cannot at present meet their obligations to us with goods or gold. We must create credits against which other countries may draw if we are to retain their trade.

This being the case, we must look upon ourselves as international bankers and world investors as well as world traders. The United States Government cannot continue to provide the money for financing our merchandise exports. Corporations and individuals in America will be called upon to step into the breach and help desirable customers who are long on credit and short on funds. Our world standing depends largely on our readiness to accept the idea of a genuine community of interest throughout the earth.

In no field of trade are our foreign opportunities greater than in coal. Germany will not be able to resume her exports of fuel for some years, if ever. Great Britain is hoping to recover her position as a coal exporter, but the obstacles in her way are increasing. She normally ships 75,000,000 tons annually, but the increased cost of production now prevailing in England and Wales may change the situation materially.

The ability of Great Britain to recover her export markets for coal depends upon her cost of production. When the war commenced, the average cost per ton of large coal at the pit mouth at British collieries was $3.60; at the close of the war it was $8.40. The better-paid miners in 1914 received $10.56 per week; in 1918 they were paid $19.20 per week. Coincident with this large advance, the Welsh miners secured a 49-hour week for surface workers, and a special fee of 72 cents per day whether they worked or not.

When in addition to the foregoing statement concerning increased wages and a shorter day we add the fact that the yearly output of the British collier has continued to fall until now he produces less than a ton of coal each day, it appears certain that English and Welsh coal will have to be sold at a high price in foreign markets in the future.



If the coal operators and miners in the United States work together in harmony, if the Miners' Union places no restrictions upon individual output, if we use more and still more machines underground, if we continue to produce from four to six times as much coal per man per day as is produced in foreign collieries, we may look forward with confidence to America's future as a coal-exporting nation. We may also rest assured that in such case the wages of American miners will be maintained on a satisfactory level.

IDEAS AND SUGGESTIONS

Hose-Clamping Tool

BY CHARLES H. WILLEY
Concord, N. H.

The tool illustrated is one that any handy man can make from a bolt and a few bits of old stock. The wire for binding the hose to its pipe or coupling is put around the hose in the manner indicated. The ends of the wire are secured through the holes of the cross-

EASILY MADE TOOL FOR CLAMPING HOSE

head. The head of the tool is placed so that the horizontal wire comes in the groove, then by holding the crosshead in one hand and tightening the screw with the other, the wire is drawn taut. When it is as tight as needed, the whole tool is turned about the wire, thus forming a hook that prevents the wire from loosening.

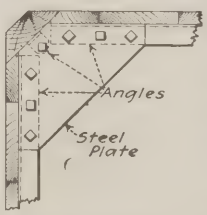
Accidents to Footmen

BY A PENNSYLVANIAN

Two men whom I have known for a long time were killed recently, while acting as footmen, one at the bottom of a breaker plane and the other at the foot of a slope. Both met death because of the failure of the "hitching staples."

A car weighing 13,000 lb., ascending a plane with a pitch of 8 deg., exerts a double shearing stress on its hitching staple bolts of about 7200 lb. Some collieries make a 1¼ in. hitching staple and others with heavier cars make them 1½ in. Both have four nuts on a standard thread. These staples go through the bumper sill of the car and are tightened against a plate ¼ x 3 in. punched to receive them.

The history of the accidents referred to above shows that the staple does not fail at the root of the thread, but breaks at the collar, which is drawn up against the bumper sill. When a mine car is derailed, it often falls between the ties, with the bumpers resting on the rail. To pull it on means a spread road and displaced ties. Accordingly, a bar is secured and tied under the hitching staple. The entire pull of lifting that car with its load is then put upon the hitching staple in a straight upward lift that fractures the metal at the point where it enters the bumper sill.



This may not always happen, but such treatment occurs again and again. Then some day, in going up a slope or plane, the staple may fail with accompanying loss of life, and destruction of cars and timber as the probable result.

Mine cars get to the shop often for repairs and their needs are tersely told in chalked inscriptions on doors and sides. But among all the cripples I have seen on shop tracks, none have been marked "Bad hitching staple." "Bad doors," "out of gage," "broken wheels," all are noted, but the car carpenters are never warned to inspect the pulling staples.

A little niche is required by law for a bottom man to step into while a car is ascending, but he cannot stay in it if he must couple trips or tend another side. He is in constant danger of falling lumps of coal coming back and hitting him, and if any inspection of the hitching staples would further safeguard him, it by all means should be made. Ropes do not often break, shackles seldom pull out, but failures of staples not infrequently bring death.

Steel Corner for Concrete Forms

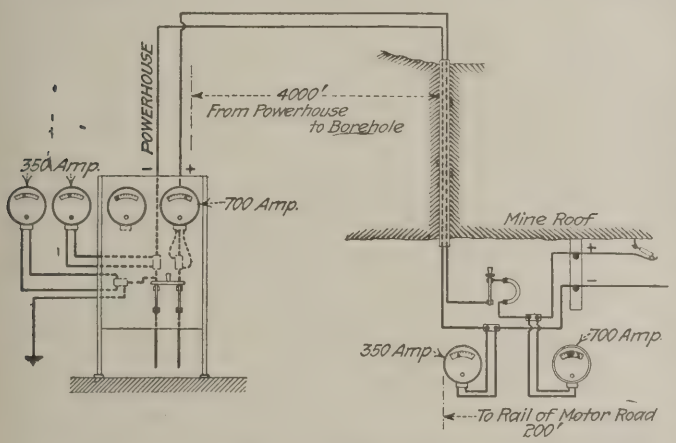
Removable corners for concrete forms have been used for some time by E. H. Oneal, of Globe, Ariz. A special type for shaft concreting is shown in the accompanying sketch. It consists of a drilled and shaped steel corner plate to which are bolted angles carrying the side planks of the form and a special corner piece. While the cost of the individual forms was high, the cost per unit of concrete was low because the forms could be used over so many times. Some were re-used 26 times and were still in good condition. To strip such a form, the bolts are unscrewed and the separate plank sections lifted out.—*Engineering News-Record.*

Bushings for Car Wheels

BY E. P. HUMPHREY
Upper Lehigh, Penn.

The supply of brass bushings having become exhausted, and the demand for mine cars still remaining great, it was necessary to find some way in which to bush the worn wheels. The axle was 3 1/16 in. in diameter in some cases, but more often it was slightly less; so the idea of using 3-in. wrought pipe for a makeshift was tried. In cases where the axles were badly worn extra heavy pipe was used. This allowed some margin also for truing up. It was with a shade of doubt as to the practicability of this method that the cars were put into commission, but careful examination later showed satisfactory service with a saving.

Importance of Good Ground Connections



By J. J. Nolan
Linton, Ind.

The object in giving *Coal Age* readers the sketch and description of a peculiar condition experienced in transmitting electric power from one mine to another, at one of the mines with which I am familiar, is to emphasize the importance of having good ground or rail connections where locomotives and mining machines operate on direct current.

As one of the mines was in need of additional power the company decided to supply one whole side of this mine, including locomotives, mining machines, pumps and fan motors, from another mine about 4000 ft. away, which happened to have a spare unit.

A borehole was drilled near the extreme inside end of the haulage road and the transmission line brought overhead from the other power plant and passed down through this hole, connecting to the trolley and rails as shown.

A connection at the power house was made from the negative line above the main switch to the engine

COURSE TAKEN BY THE TRANSMISSION LINE

bed plates, interconnecting with pipes around the plant that extended under ground. This method was followed at all of this company's plants.

It was decided to make a test of amperage and drop the line voltage at the bottom of the drill hole with an average load to see if the line might require additional copper. Only one ammeter was used in the original test, and this was connected in the positive line.

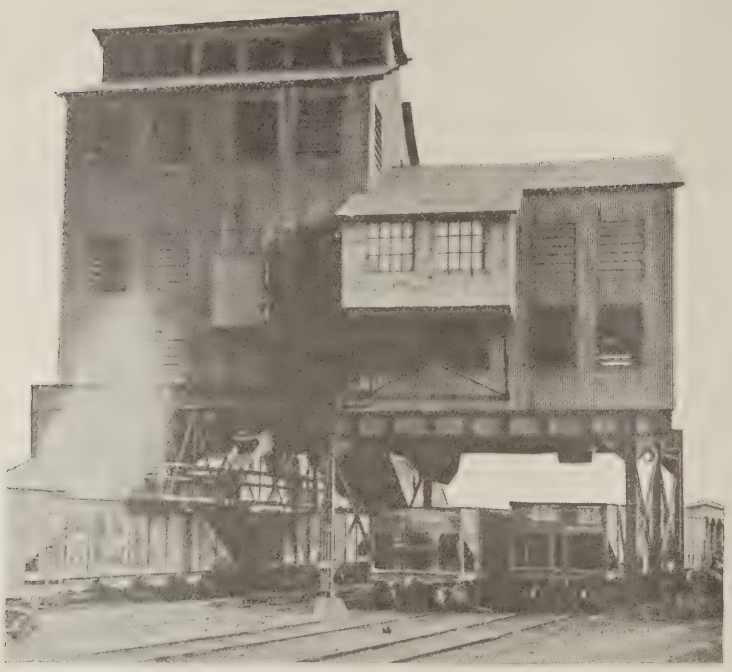
The load varied from 300 to 700 amperes. The voltage drop was not considerable, but near the completion of the test it was noticed that the positive line became quite warm while the negative, which was of the same cross-section, remained cool. This led us to connect an additional ammeter in the negative line, as shown. The reading on this instrument was about half that of the positive line.

Making note of these readings we removed the meters, and proceeding to the power house we connected them as shown at the left of the switchboard, one in the line leading to earth and the other in the overhead line. This was done to satisfy ourselves as to whether this large amount of current could be coming through the earth for this distance, since there were no connections underground of workings between the two mines which might allow current to find its way along pipes or rails.

The readings of the positive and negative overhead lines leaving the board showed the same ratio as existed at the bottom of the borehole. The ammeter on the negative ground line showed the balance of the negative load, which amount came this distance through the earth.

Upon examination of the connections around the switch and rails at the extreme inside end of the haulage road, several poor connections were found. This accounted for a large part of the current at this point taking the path of least resistance, which was the earth. Making all connections in a proper and secure manner at this point did not materially lessen the voltage drop from the readings taken before.

Discontent and Its Remedy



Of the many kinds and degrees of diseases the most pernicious and far-reaching is the mental disease of discontent. However, it is only when this discontent is turned into vicious channels that it becomes dangerous, because discontent may also be the index of a progressive mind. If it is correctly diagnosed, and the proper remedial measures are applied, discontent in a body of workmen may be cured. The old idea that this particular disease can be cured by the methods of an Indian medicine-man should be discarded forever. The ailment, like all human ills, especially those of a mental nature, requires delicacy in treatment inasmuch as the patient generally lacks faith in the practitioner. More and more corporations are coming to realize that labor must be as carefully considered and developed as expensive mechanical equipment. This is perhaps more true of the coal industry than of many others, owing to the varied character of the labor supply.

The problem of unrest is broad and constant. While almost all coal corporations have welfare bureaus of one kind or another, the real way in which to handle the problem is to squarely recognize that the problem exists, and to place the responsibility of its solution in charge of an official who shall pay attention to nothing else.

This official may be a full-fledged personnel efficiency expert or just an ordinary executive who knows workingmen and has the ability to handle them. His task should not be that of an autocrat with a religious fervor to crush out all discontent among his charges. Rather it should be to discover the real cause of the discontent and then to apply the correct remedy.

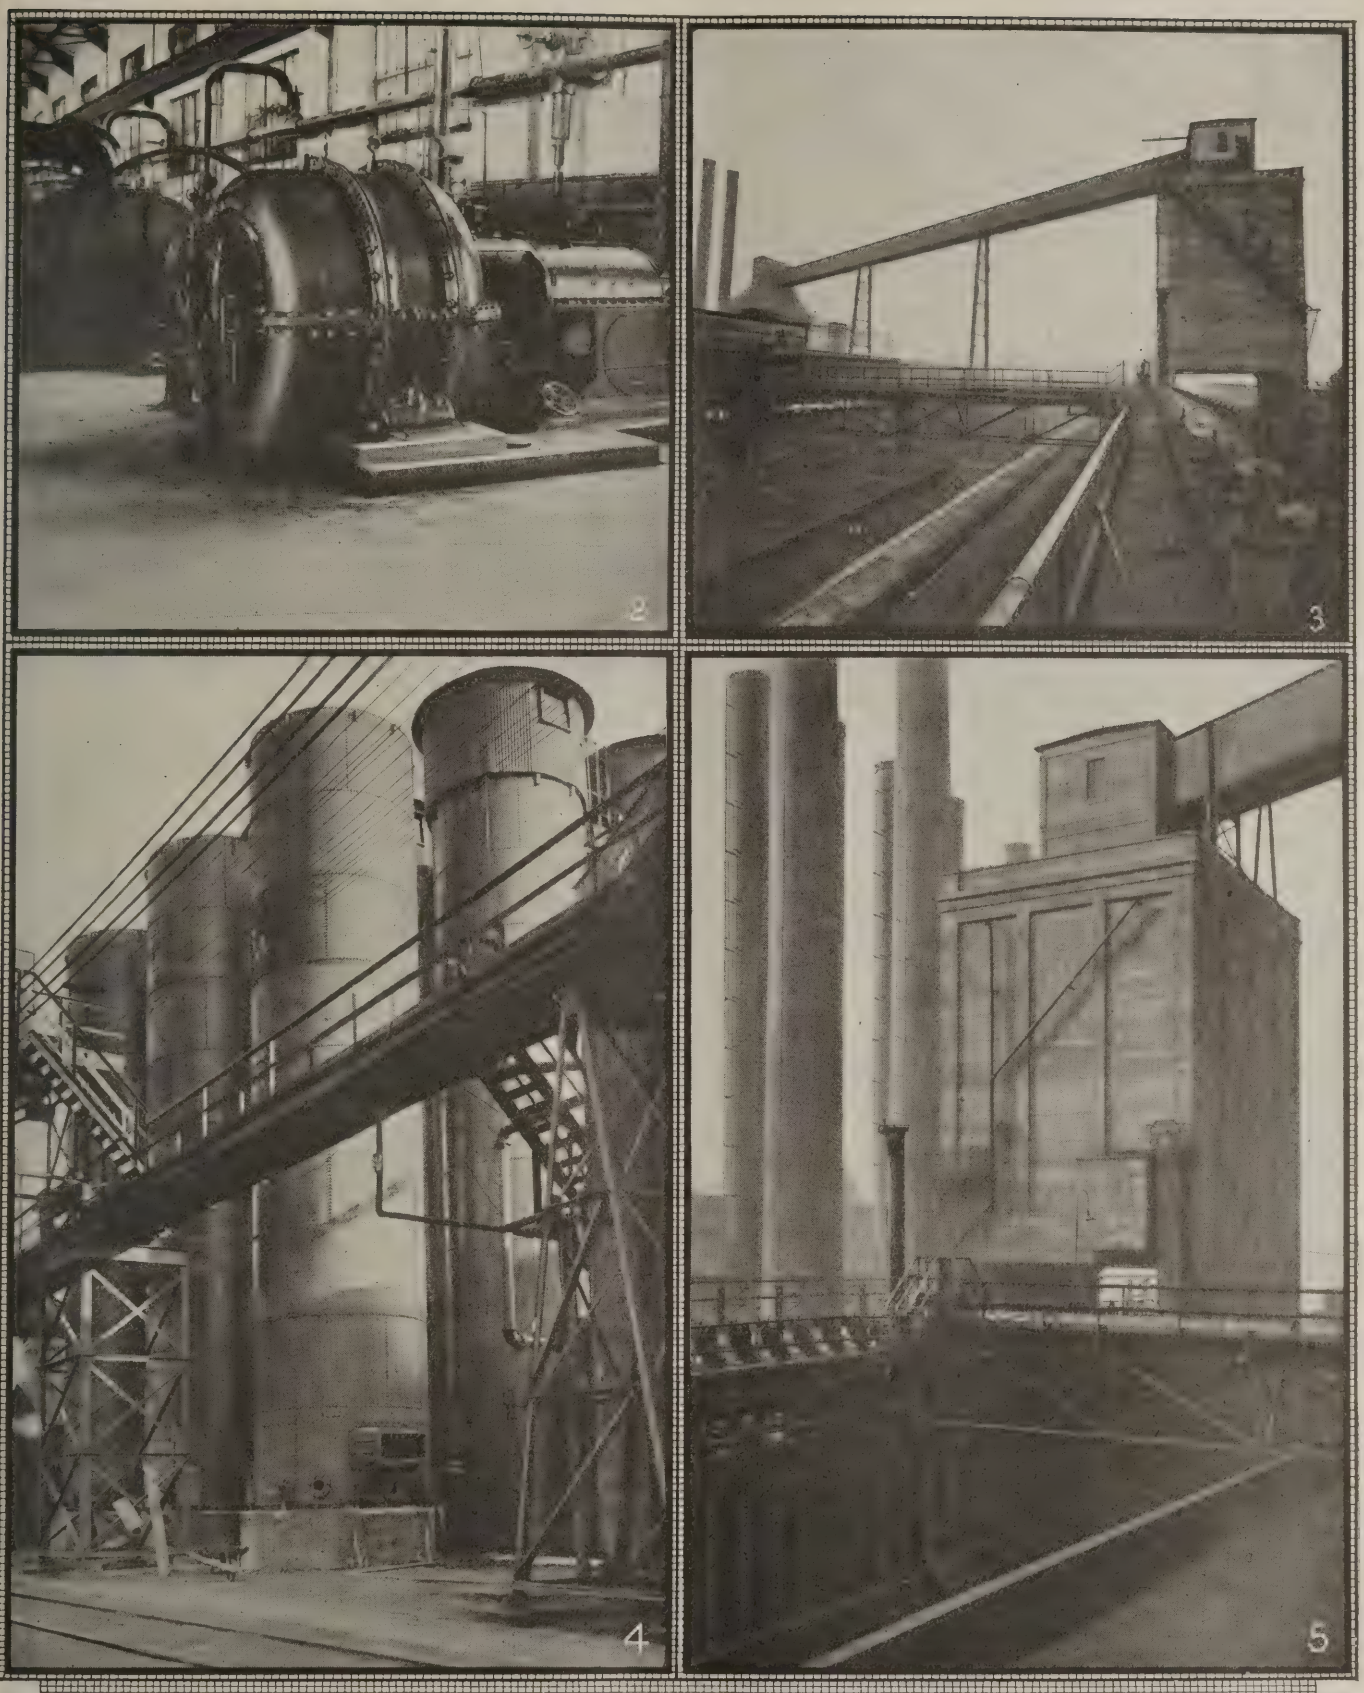
As stated before, this discontent may be only the desire of a workingman to advance to a better position, or it may be due to the fact that a workingman is unfitted for his present job and would be happier at another task more suitable to his inclinations. In a way the official I have in mind would be a surgeon to all the petty industrial ills to which the labor body of an industry is heir. Hand in hand with him should work the medical doctor, whose duty it would be to attend to the physical well-being of the workingmen.

Obviously, discontent means slowing up in work, in enthusiastic application, and in the desire to become more efficient. Even ill-health cannot affect a workingman's power to labor as much as can vicious discontent. And as this is a remedial disease, the only way to cure it and to keep it cured is to employ a man who is competent to handle the job wisely. While there may be no tangible dividends from this form of investment, no one can deny that it will prove profitable. It has been tried and adopted with success in other industries so it is beyond the experimental stage; and there is no good reason why the coal industry should lag behind.

In the last three months of 1918 the by-product coke plants attained their maximum capacity. Although they gained only a slight supremacy over the beehive ovens during that period, it is certain that the latter type of oven has seen its best days. The operation described in the following pages is typical of the coke-making facilities found in the modern byproduct coke plant. The illustration at the left shows the screening plant, where coke is separated into different grades.

SOME STRIKING FEATURES of a LARGE BYPRODUCT COKE PLANT*

IN order to supply coke for its blast furnaces at Hubbard, Ohio, the Youngstown Sheet and Tube Co. has increased its coke-making facilities 50 per cent. Since August, 1916, the company has operated four batteries of ovens at its East Youngstown coke plant. Ground was broken for the two new coking units in July, 1917. On Aug. 8, 1918, the first battery was placed in operation, followed by the second on Sept. 4, 1918. These two batteries consist of 51 ovens each. They are of the Koppers cross-regenerative type of 500 cu.ft. capacity.



The unloading, crushing and mixing equipment for the original four batteries was designed and installed with sufficient capacity for the extension which was foreseen at that time. The coal is unloaded by means of a high-lift car dumper which is said to be the first one ever installed to serve a coke plant. It was built by the Wellman-Seaver-Morgan Co., of Cleveland, Ohio. A 36-in. belt conveyor, 350-ft. centers, with a capacity of 500 tons an hour, was installed from the top of the storage bin over Nos. 1 and 2 batteries to the new storage bin over the new Nos. 5 and 6 batteries. This bin is of 2000 tons capacity and has a partition so that different mixtures of coal can be handled on the two batteries and also so either side of the bin can be conveniently cleaned without interfering with operations. Clean-out manholes are provided near the top of the hopper in each compartment.

In leveling the coal in the ovens after charging, some coal is often pulled out through the chuck door. Therefore it was decided to incorporate in the new work an arrangement for handling this spillage which had been developed by the Youngstown Sheet and Tube Co. for the old batteries. Accordingly a small bin of about three tons capacity was built on the main bin. The coal pulled from the ovens is dropped through a chute attached to the pusher into a hopper from which it is conveyed, elevated and discharged into the small bin. The operation is designed so that the doorman on the pusher car drops the coal from the hopper and starts the conveyors. The small bin is so arranged that the larry man can empty it without getting off his larry car. This is said to be the first installation of its kind on a byproduct coke plant.

The two larry cars are equipped with a motor-driven swab crane designed by the Youngstown company and are the same as installed by them on the three larry cars on the old batteries. The object in putting a motor on this apparatus was to make the work so easy that the larry men can attend to this duty without extra help.

Owing to the increased coal consumption due to the extension, it was considered advisable to erect a thaw house for taking care of frozen coal. Accordingly a thaw house 400 ft. long was built to hold 20 cars and span two main tracks and the track to the car dumper. The construction is of reinforced precast concrete columns supporting structural steel trusses and the roof and machinery house. The walls between the columns are built up of interlocking hollow tile. The hot-air ducts run the length of the building on both sides between the roof and the bottom chord of the roof trusses; the return air duct is between the hot-air ducts. From the hot-air ducts pipes convey the heated air up under the cars every 5 ft. on both tracks the entire length of the building.

*Reprinted from the Jan. 23, 1919, issue of the *Iron Trade Review*.

Some Views of an Up-to-date Byproduct Coke Plant

Fig. 2—Boosters shown increase the pressure of the coke-oven gas after the byproducts are extracted. Fig. 3—This concrete storage bin is partitioned for each compartment. Fig. 4—Cooling towers near the byproduct building. Fig. 5—Concrete storage bin of 2000 tons capacity. Coke ovens below.

The furnace and machinery houses contain two heating units and fans for delivering and exhausting the hot air. Temperature regulators are provided for automatically controlling the temperature of the air used in the furnaces. Recording pyrometers and thermometers are also installed. Coke-oven gas is used for heating the air. Automatic control is provided for shutting off all the gas except the pilot lights when the fans are shut down accidentally or intentionally. The fans are each designed to deliver 60,000 cu.ft. of air per minute at standard conditions. The air is delivered under the cars at about 225 deg. F., and after passing up along the sides and bottoms of the cars passes into the return air duct through openings in the bottom and on to the heating furnaces. The openings in the bottom of the return air duct are adjustable so that an even distribution of hot air throughout the length of the building is obtained by making the proper adjustments in these openings.

The coke wharf is 125 ft. long and is located at one end of the batteries. Considerable care was given in selecting the location of this wharf so that it would not be in front of the ovens, thereby avoiding the troubles—especially prevalent in cold weather—from steam along the coke side of the batteries. Two locomotives for pulling the quenching car are provided. They were built by the General Electric Co., Schenectady, N. Y. The quencher car track is built with 100-lb. rails and is supported by a reinforced-concrete bed.

From the wharf the coke is conveyed on a 36-in. conveyor, 340-ft. centers, to a new screening station erected for the new batteries. Provision is made by means of a tunnel underneath the quencher track between the wharf and the screening station, so that if in the future the company builds blast furnaces on the coke-plant site a conveyor can be installed to take the coke to a screening station over the blast-furnace trestle and deliver into a transfer car running over the blast-furnace bins. The coke is screened over bar grizzlies, of which there are two; one is reserve equipment and can easily be pulled into position in front of the conveyor when it is desired to remove the bars of the other grizzly.

As a somewhat softer coke is desired in the present operation, special precautions were taken to save breakage of the coke and wear on the chutes from the bar grizzlies to the railroad cars. Coke may easily be delivered into cars on either of two tracks running underneath the screening station. The undersized coke from the bar screens drops onto a 20-in. belt conveyor and is delivered to a revolving screen in which the separation is made into domestic and breeze grades.

Coke, after being screened, is delivered into small bins and from there transported over the river on a trestle to the blast-furnace bins by means of a 35-ton electrically driven transfer car. All chutes are lined with hard brick laid on edge and the sides of the chutes are lined with chilled cast-iron plates. In the new plant glass windows are practically eliminated and steel louvers substituted. Owing to the wharf having been located below the sewer level, an automatic electrically operated bilge pump is installed to take care of drainage water. A car-pulling winch which handles 12 loaded cars and serves both coke-loading tracks is installed to spot empty cars and move away the loaded ones.

A brick quenching hood 58 ft. high is provided. Steel baffles inside of the hood return any coke into the quencher car which may fly into the air during the process of quenching. All concrete foundations for the hood which might come in contact with water from the quencher car are veneered with brick. The same type of solenoid-operated balanced quenching valve, which the company was the first to adopt for this use, is installed in the new quenching station in the same manner as in the old plant.

Except for lowering the horizontal flue 2 in. there is practically no change in the new ovens over the old. In both cases the oven width is 17 and 19½ in., or an average of 18¼ in. wide. It was considered desirable, primarily on account of the men's comfort in hot weather, to insulate the regenerator end walls. Accordingly, the company conducted some exhaustive tests in a specially built furnace, on a variety of insulating materials; finally a moderate-priced grade of infusorial earth was put in between the firebrick and the red brick closing the face of the regenerators. The pusher machines, which were built by the Wellman-Seaver-Morgan Company, are practically the same as on the original installation. The cast-steel end trucks are provided with countershaft bearings on both sides so that the end trucks are interchangeable and but one spare need be carried for both trucks. The ovens, pusher track, walls, coal bins and concrete battery stacks are carried on concrete piles.

The original installation in the byproduct building consisted of three positive-type exhausters delivering through tar extractors and preheaters to three large oval-type saturators, one unit being a spare one. Two positive-type boosters were provided for delivering surplus gas to the mills, one being a reserve. The exhauster and booster fans were built by the Connersville Blower Company of Connersville, Ind. The extension consists of a General Electric turbo exhauster, tar extractor, preheater and saturator and one General Electric turbo booster for the surplus gas. The gas

FIG. 6. CENTRIFUGAL WHIRLERS FOR RECLAIMING SULPHATE IN CRYSTALLIZED FORM

FIG. 7. QUENCHING BUILDING EQUIPPED WITH 58-FOOT HOOD AND PLANT WHERE COKE GOES THROUGH FINAL PROCESS OF MAKING

is admitted to the continuous oval cracker pipe in the new saturator at both ends. This type of saturator was adopted in preference to the type originally built, in which the gas was all admitted at one end into two separate cracker pipes.

The regulation of the gas in the collecting main is accomplished by the turbo exhauster and governors on the offtakes, the other exhausters being run at constant speed. Two new primary coolers, a storage tank for weak liquors and an ammonia still were added.

The Youngstown Sheet and Tube Co. designed and built a jib crane operating a one-half yard, single-line, grab bucket for cleaning out accumulations in the hot-drain and flushing tank. This bucket, which was furnished by Edgar E. Brosius, of Pittsburgh, Penn., empties into a small dump car running on a narrow-gage track. The car delivers the material to a pit within reach of a standard railroad track where it can be gathered by a locomotive crane. By this device men are never required to enter the hot-drain or flushing tanks to clean out accumulations. An interesting feature of this tank which was designed by the company is the absolute and simple control of the proportions of tar and liquor for flushing purposes. The mixture is ordinarily carried at 50 per cent. each, but can be varied almost instantly by a valve to any desired proportion of tar and liquor. By means of this and other control features the primary coolers, which ordinarily have to be steamed out every few days, are run from four to six weeks at a time without such attention, which effects considerable saving of steam, labor and deterioration, due to expansion and contraction of the large number of tubes in these coolers.

In the sulphate storage room is a hopper, with a chute extending through the wall, whereby bulk shipments can be made by means of the overhead crane loading into the hopper; the salt runs directly into the box car instead of having to be wheeled into the car by hand. A loading hopper for bag shipments is also built. Sulphate of ammonia often cakes more or less while in storage, and when loading into bags through the usual hopper it is necessary to have a man on top of the hoppers to push the salt down. By means of a special design of toothed rolls the salt is fed into the bags without any hand labor.

The original benzol plant and the addition were built by the Semet-Solvay Co. The latter consists of two light-oil stills and one refining still, also auxiliary apparatus, wash-oil coolers, gas coolers and gas scrubbers. A new acid washer building was erected entirely separate from the main benzol building and so arranged that all apparatus can readily be taken down and removed from the building for any repairs which might be dangerous in this location. Overhead hand-operated traveling cranes are installed in both the main benzol building and the acid washer building. All new work rests on concrete piles, as was the case with the original work. In constructing the additions particular care had to be exercised on account of the hazards of the industry. The concrete pile driver was furnished steam through a hose to avoid the use of the boiler. All field work on the structural steel was bolted, no riveting being permitted on the site.

One new Babcock & Wilcox boiler was installed with Coxe traveling chain-grate stokers, with which the entire boiler house is equipped. Coke breeze produced at the coke plant is used for fuel. Gas burners are installed for emergency use only or for use Saturday night or Sunday in case the surplus gas would otherwise be wasted.

The three Wheeler forced-draft cooling towers originally installed were made large enough to take care of the extension. It is necessary in summer to use two of these towers for cooling the river water for use in the primary coolers and the first section of the wash-oil coolers. The third tower is used for recirculating water for the first cooling of the gas leaving the byproduct building and is a closed system. Cold water from a nearby reservoir is used for apparatus inside the benzol building, final cooling of the gas before the benzol scrubbers and final cooling of the wash oil, but this is reduced to a minimum by cooling as far as possible with the cooling-tower water as a preliminary step.

Coal and Phosphate in Southeastern Idaho and Western Wyoming

Coal has been mined in a small way in the Bighole Mountains, Teton County, Idaho, for many years, to supply the local demand. The coal is of excellent quality and the chief drawback to its wider use has been the remoteness of the mines from the railroad. During the war the greatly increased demand for fuel led to an increase of interest in this field, and late in 1918 preparations were being made to build a railroad spur to the mines from the Teton Valley Branch of the Oregon Short Line Railroad. When this track is completed Idaho may rank higher as a producer of coal.

The United States Geological Survey, Department of the Interior, has recently issued, as Bulletin 680, a report by A. R. Schultz, which describes the coal fields of the Bighole Mountains and other districts in this part of Idaho and the adjacent part of Wyoming. The report also describes extensive phosphate deposits in the same general region. The existence of these deposits has been known for more than 10 years, but their extent was not known until they were mapped in detail and sampled by Mr. Schultz.

Selection of the Electrical System, Voltage and Frequency for Mine Service

By Terrell Croft
University City, St. Louis, Mo.
(*Copyright—All Rights Reserved*)

SYNOPSIS—*For direct-current distribution a voltage of 250 is practically a standard at American coal mines. Some installations have been and still are made at 500 volts, but such a potential should be avoided where possible. In alternating-current distribution a frequency of 60 cycles is usually adopted, although some plants operate at 25. Alternating-current voltages range from 110 upward.*

WHETHER direct or alternating current should be used in a mine must be determined by local conditions. If mining locomotives are to be operated, the use of direct current is almost imperative. For a mining property of any considerable extent, high-voltage alternating-current transmission and low-voltage direct-current distribution are usually the most economical and satisfactory course to follow. If energy is to be transmitted for over, say, four or five miles, high-voltage alternating current is ordinarily the only logical solution on the basis of sound economics; 2200 volts can be used for distances of possibly up to four miles, although it is probable that 6600 or even 13,000 volts may be more desirable, particularly if there is a possibility of the system being extended to greater distances in the future. Where power purchased from a public utility company is to be utilized, this will, in practically every case, be alternating current. Substations and transmission system will be designed accordingly.

TABLE I. PROPORTION OF MINING LOCOMOTIVES OF DIFFERENT TYPES IN MINES IN THE UNITED STATES

(The data for this table were furnished by two of the largest manufacturers of electric mining locomotives)

	Coal Mines		Metal Mines	
Type of Locomotive	Manufacturer A Per Cent.	Manufacturer B Per Cent.	Manufacturer A Per Cent.	Manufacturer B Per Cent.
500-volt, direct current	8	15	10	20
250-volt direct current	67	70	64	70
Storage battery	25	15	26	10.
Three-phase and single-phase, alternating current	0	0	0	0

Concerning whether single-phase, two-phase or three-phase alternating current should be used, it may be stated that the three-phase system only is used in modern installations. This is because this system is much more satisfactory and economical for the majority of installations than is either the single-phase or the two-phase. Two-phase equipment is seldom if ever installed now except as additions to existing two-phase installations. Single-phase equipment is never used except for electric lighting and where the power requirements are exceedingly small. The three-phase system requires only 75 per cent. of the copper of an equivalent two-phase or single-phase system and necessitates only three wires as against the four ordinarily used with the two-phase system.

The standard frequency for alternating-current power transmission and distribution may now be stated to be 60 cycles. It appears that it is desirable in practically every case to adopt this rather than any other frequency. The economies and advantages which were expected to result from the use of 25 cycles for electrical energy transmission have not, in general, materialized. A number of plants which generate at 25 cycles have been constructed, which necessitates the installation of 25 to 60 cycle frequency changers where 60 cycles is the utilization frequency.

Voltages used in mines may be classified into (a) low pressure, (b) medium pressure and (c) high pressure. These terms are defined by "Standardization of Electrical Practice in Mines," Circular No. 23, Bureau of Standards, as follows:

A low-pressure system is one where the conditions are such that the pressure between any two conductors or between any conductor and the earth, at the terminals where electricity is being used, cannot exceed 300 volts.

A medium-pressure system is one where the conditions are such that the pressure between any two conductors or between any conductor and the earth, at the terminals where electricity is being used, can exceed 300 volts but cannot exceed 600 volts.

A high-pressure system is one where the conditions are such that the pressure between any two conductors or between any conductor and the earth, at the terminals where electricity is being used, can exceed 600 volts.

The power lost in an electrical circuit transmitting a given load varies inversely as the square of the impressed voltage. This is strictly true if certain factors which affect only very high voltage alternating-current lines are disregarded. If the voltage impressed on a line is doubled, the watts of line loss (a certain amount of power being transmitted) will be quartered. If the impressed voltage is trebled, the loss will be one-ninth of that with the original voltage. The truth of these statements may readily be verified by applying Ohm's law to hypothetical cases. This explains why a high voltage is, from the line loss standpoint, desirable for electrical energy transmission.

The weight of conductor is, for a given loss, inversely proportional to the square of the impressed voltage. That this is true follows from the statement of the preceding paragraph.

The proper voltage for the distribution of electrical energy in and around a mine must be determined by the requirements and conditions affecting each installation. Formerly, 500 volts was the standard pressure but because of the life and fire hazard which this potential involves it has been superseded by a lower one. In mines where electric locomotives are operated, direct current at a pressure ranging from 220 to 275 volts is preferably used. Some mines in West Virginia (Ohio Brass Co.) operate a three-wire system at 500 volts between outside wires and 250 volts between outside and neutral.

A generally accepted rule is to limit the range of distribution for 250 volts to one mile and for 500 volts to four miles. However, it is frequently necessary to carry electric power at 250 volts into mines for greater distances than one mile. This necessitates a correspondingly greater investment for feeder copper. Pressures exceeding 300 volts are usually fatal to life, particularly so under the conditions of dampness often occurring in mines; hence these are undesirable for mine traction service.

TABLE II. VOLTAGES ADVISABLE FOR LINES OF VARIOUS LENGTHS IN THREE-PHASE TRANSMISSION (GENERAL ELECTRIC CO.)

Length of Line	Voltage
Up to 1 mile	500 to 1,000
1 to 2	1,000 to 2,300
2 to 3	2,300 to 6,600
3 to 10	6,600 to 13,200
10 to 15	13,200 to 22,000
15 to 20	22,000 to 33,000

Where a haulage system extending for a considerable distance is to be installed, it is desirable to locate underground substations so as to minimize the direct-current transmission distance so that 250 volts can be used economically. In such substations synchronous converters or motor-generators can be installed whereby high-voltage alternating current can be converted to low-voltage direct current. A 125- to 250-volt direct-current three-wire system is often desirable.

For alternating-current distribution to medium capacity motors 220 volts is usually the preferable pressure. Large motors may be served economically with 2200 or even a higher voltage.

About 1000 volts per mile for alternating-current long-distance transmission (H. B. Gear) is a rule of thumb which serves as an index. This is based on the fact that with copper conductors and a pressure of 1000 volts per mile with a current density of one ampere per 1000 circ. mil the energy loss will be about 10 per cent. That is, a line designed on this basis will carry its current without excessive heating and at about 10 per cent. loss. For relatively short lines transmitting considerable power the rule provides a conductor too small for most economical operation—that is, for minimum annual costs. Hence, for the short-distance transmission of much power a pressure greater than 1000 volts per mile may be more economical. Where a transmission system serves an extensive distance and the load is small, a voltage smaller than "1000 per mile" may sometimes be adopted with economy.

TABLE III. SIZES OF WIRE FOR THREE-PHASE TRANSMISSION SERVICE

Approximate distances over which 100 kw., three-phase current, can be transmitted with different sizes of wires at different voltages, assuming an energy loss of 10 per cent. and a power factor of 85 per cent.

No. B.&S.	Area in Circular Mils	Voltage of Line — Distance of Transmission of Various Potentials at Receiving End, in Miles								
		2000	3000	4000	5000	6000	8000	10,000	12,000	15,000
6	26,250	1.32	2.98	5.28	8.27	11.92	21.12	33.1	47.68	74.50
5	33,100	1.66	3.75	6.64	10.40	15.00	26.56	41.6	60.00	93.75
4	41,740	2.10	4.74	8.40	13.15	18.96	33.60	52.6	75.84	118.50
3	52,630	2.54	5.96	10.16	16.55	23.84	40.64	66.2	95.36	149.00
2	66,370	3.33	7.51	13.32	20.85	30.04	53.28	83.4	120.16	187.75
1	83,690	4.21	9.48	16.84	26.32	37.92	67.36	10.53	151.68	212.00
0	105,500	5.29	11.92	21.16	33.10	47.68	84.64	132.4	191.72	298.00
00	133,100	6.71	15.11	26.84	41.97	60.44	107.36	167.9	241.76	377.75
000	167,800	8.45	19.04	33.80	52.85	76.16	135.20	211.4	304 64	476 00
0000	211,600	10.62	23.92	42.48	66.42	95.68	169.92	265.7	382.72	598 00

Example—What size wire should be used to deliver 500 kw. at 6000 volts, at the end of a three-phase line 12 miles long, allowing an energy loss of 10 per cent. and a power factor of 85 per cent.? Solution—If the example called for the transmission of 100 kw. (on which Table III is based), look in the 6000-volt column for the nearest figure to the given distance, and take the size wire corresponding. But the example calls for the transmission of five times this amount of power, and the size of wire varies directly as the distance, which in this case is 12 miles. Therefore, look for the product $5 \times 12 = 60$ in the 6000-volt column of the table. The nearest value is 60.44 and the size wire corresponding is No. 00, which is therefore the size capable of transmitting 100 kw. over a line 60.44 miles long, or 500 kw. over a line 12 miles long.

If it is desired to ascertain the size wire that will give an energy loss of 5 per cent., or one-half the loss for which Table III is computed, it is only necessary to multiply the value obtained by 2, for the diameter varies directly as the per cent. of energy loss.

Do British Miners Shirk Tax Payment?

BY AN ENGLISH COLLIER

The coal scarcity in Britain has become a serious problem. To a large extent the existing situation has been brought about by Bolshevism, and the remedy must be patriotism to a similar extent. The miners' leaders are appealing for support from their men. Only a little time back, however, they would not hear anything of the suspension of the Eight Hours Act, although at the time it was going through the various stages of enactment they allowed a section to read that in the case of emergency the act could be suspended.

If Great Britain is not in a national emergency at present, I do not know, and dare not think, what conditions will be like when it is. But the miners will not even give way to let the 60 hours per year extra be worked. Apparently some men will not work as it is, but there are quite a number who would put in extra time for the sake of the country if allowed to do so. Such men, of course, find other work of national importance to do, such as gardening, etc. The most recent figures show that in 1917 there were 7,875,232 tons less coal turned out than was produced in 1916, in spite of the fact that 23,277 persons more were employed. There was an increased output in the Yorkshire and North Midland district, but there were here 244,329 persons employed against 239,331 in 1916.

Considering the output per man in 1916, there ought to have been turned out 300,000 tons more in 1917. The actual figures for the districts named were:

1917	69,128,836 tons
1916	68,005,505 tons

Only three districts in the country had an increased output in 1917 over 1916.

This side of the question then must be absenteeism. What is the cause therefor? There may be many causes, but the one that could most easily be removed is the income tax. This is undoubtedly the cause of much absenteeism. It is next to an impossibility to get some men to make any overtime if their ordinary six days bring them anywhere near being taxed. Scores who used to work well would rather take holidays than pay out any portion of their wage in income tax, even if their income is made considerably less through this.

Bumps and Outbursts of Gas in the Crowsnest Pass Coal Field*

THE Crowsnest Pass coal field is located in the extreme southeastern corner of British Columbia only a few miles removed from the northern boundary line of the United States. It is regarded as the most important coal field in the province. The field presents unusual natural difficulties to mining as the coal beds are at the base of an elevated plateau; the coal is under heavy cover requiring great care in mining to avoid squeezes and "bumps," and it practically can only be reached through the outcrop.

This coal field is in the form of an elevated trough, narrow at the north end and wide at the south, the southern part broadening toward the southeast (Fig. 1). The extreme length north and south is 35 miles and the greatest width along the southern half, a little south of Coal Creek, is 13 miles. The field covers 230 square miles and is estimated to contain in seams over 1 ft. thick, 22½ billion tons of bituminous coal in actual reserve, 20¾ billion tons in probable reserve and two billion tons, in beds 2 ft. thick and over at depths greater than 4000 ft. and less than 6000 ft., which might be expressed as possible reserves—or a total of over 45 billion tons. A number of the seams are too thin and too impure to mine with commercial success at the present time; it is considered that the available coal does not have an aggregate thickness—in beds 3 ft. or more thick—of more than 100 ft. Furthermore, some of the thickest beds, 10 to 20 ft. thick, owing to friability of the coal and poor roof, cannot under present conditions be cleanly mined out, and there is in consequence much loss of coal.

The Crowsnest basin has been buckled into a north and south synclinal trough by the great dynamic forces pressing from either side in the uplifting of the Rocky Mountain ranges. As a consequence, around the edges of the basin the beds have been steeply uplifted. While the more rigid sandstones and conglomerates overlying the more important coal seams have protected the latter, there is abundant evidence of disturbance, including a lateral squeezing of the coal to increased thickness in which it was badly crushed in places. Also there has been some local faulting of the coal beds, which causes much difficulty in mining operations. The dips of the coal beds from the edges of the basin probably carry the lowest beds down, in the middle of the trough, to such depths that under the highest ridges there is from 3500 to 5000 ft. of cover over the lowest beds. The accompanying cross-sections, Figs. 3 and 4, referred to the mine map, Fig. 2, for location, indicate the direction and amount of dip of the beds at the Coal Creek colliery.

The coal beds in any one locality are well defined, but it seems to be difficult to correlate the beds in the different sections as the beds change their characteristics and the adjacent rocks are said to lack distinctive features. The coals in the different beds that have been worked at Coal Creek, Hosmer and Michel do not differ much in chemical composition and are coking coals; but the coal at Morrissey had evidently been subjected to more intense crushing and the percentage of fixed carbon is higher. The Crowsnest field produces a good grade of bituminous coal, the different beds in any one locality having about the same kind of coal. Except at Morrissey, where the fixed carbon is too high to permit of making coke in beehive ovens, the coal makes a good

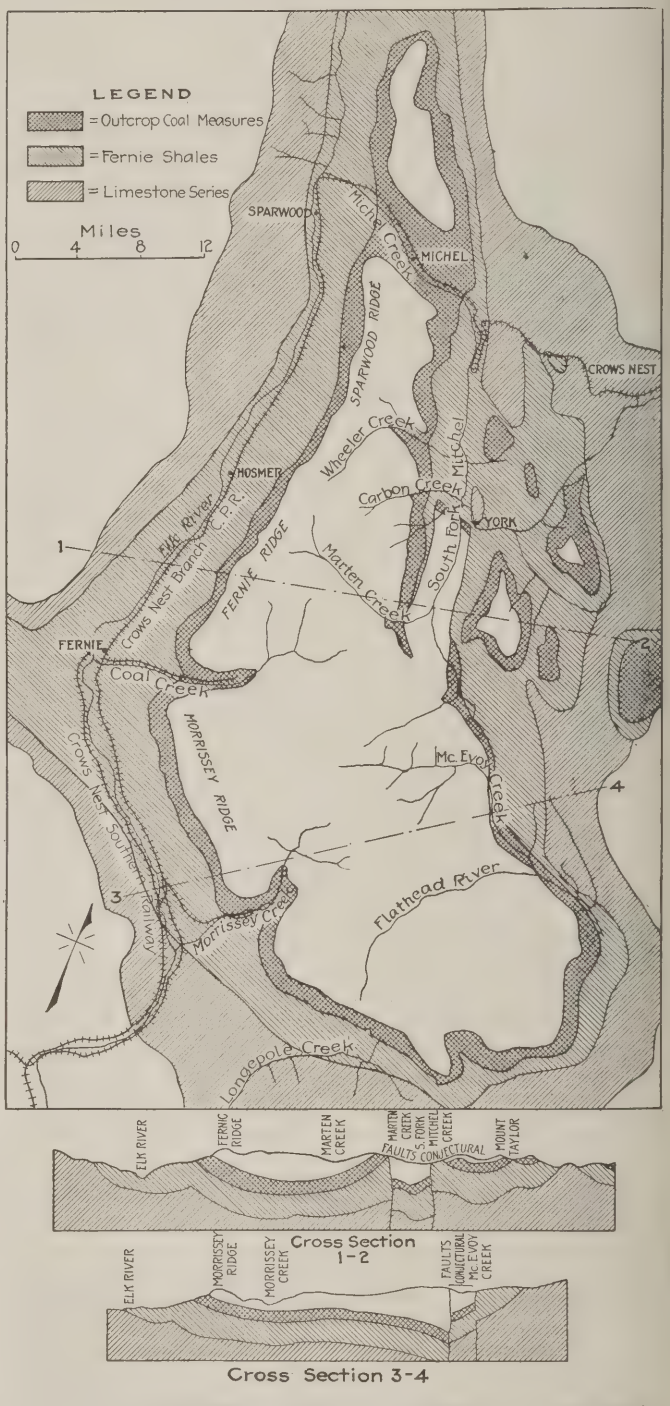


FIG. 1. CROWSNEST PASS COAL FIELDS IN BRITISH COLUMBIA, CANADA

*A digest of Bulletin No. 2, 1918 (British Columbia Department of Mines), on "Bumps and Outbursts of Gas in the Mines of Crowsnest Pass Coalfield"—a report by George S. Rice, E.M., chief mining engineer, U. S. Bureau of Mines.

metallurgical coke. There are 440 ovens at Fernie, coking Coal Creek coal, and 480 at Michel.

In this article the principal interest centers on the beds at the Coal Creek operations. Six seams have been prospected here, but of these only Nos. 1 and 2 have been found to be commercially minable at present. Normally these beds are from 75 to 150 ft. apart, but in certain parts of the Coal Creek mines the beds come together. The following are typical sections of these beds:

SECTION NO. 2 BED

Roof, Strong Shale (in Places Sand, Shales and Sandstone)

Coal	3 ft. 6 in. to 8 ft. 0 in.
Rock with streaks of coal	1 ft. 8 in.
Coal, high in ash (gaseous)	1 ft. 4 in.
Floor, shale	

SECTION NO. 1 BED

(75 to 150 ft. Above No. 2 Bed)

Main roof, massive shale and sandy shale	
Roof coal clean, friable	2 ft. 6 in. to 3 ft.
Rash, slickensided shale with coaly layers	1 ft. to 4 ft.
Coal, columnar structure, soft, clean	9 ft. to 13 ft.
Floor, shale (strong)	

ANALYSIS FACE SECTION SAMPLES, COAL CREEK MINES

No. 3.....	Face main level....	0.70	24.05	66.05	9.20	0.57	14,081

The Crowsnest coal mines have the unenviable position of being among the most gaseous mines in the world, according to records of analyses of mine-air samples through the British Columbia Mining Department. In No. 1 East mine of the Coal Creek collieries on Apr. 14, 1916, when the mine was working, 2906 cu.ft. per minute of methane was given off. This quantity represents the maximum discharge from any of the mines in the field according to the records. At this rate there was thrown out of the mine in 24 hours 4,184,600 cu.ft. of methane, which would weigh 78 tons. The production of coal was then about 1500 tons, or about 2790 cu.ft. of methane for each ton of coal mined. It was thought that the greater part of this flow came from the coal stratum rather than that it was liberated from the breaking down of the coal in mining.

As illustrating the great outbursts of gas which take place in this field, a remarkable case is cited which occurred at the Carbonado mines of the Crowsnest Pass Coal Co. These mines were opened up on Morrissey Creek, about seven miles south of Coal Creek. In 1903, when the main entry had been driven in 2000 ft. from the outcrop, a great outburst of gas occurred in which it was stated that over 1400 tons of coal was blown out of the face of the main entry. In 1904 there was another great outburst in which 14 men were killed, the coal thrown out filling the entry for 400 ft. according to the inspectors of the district. The displacement of coal in this instance was estimated by the management to amount to 3500 tons. The volume of gas given off in the last 30 minutes after the outburst was estimated by various authorities at from two to five million cubic feet. No such great instantaneous outbursts have occurred in mines other than the Carbonado, but lesser, slower outbursts have taken place in the Coal Creek mines. In some virgin areas of this latter mine, when entries have been advancing on three shifts, it has been found necessary to slow the advance, on account of gas given off, by cutting out one or two of the shifts.

Methane outbursts into coal mines have not been uncommon in many coal fields besides the Crowsnest, but such outbursts have occurred only when the coal bed being mined is deeply covered to a depth of over 1000 ft. or more by strata containing impervious shales. Methane found in coal measures is generally believed to have been derived from partial distillation of the bituminous matter in the coal seams and bituminous shales, in the natural process of coal formation by chemical reactions aided by heat and pressure from deep burying and mountain upbuilding. It is therefore believed that all coal beds have produced large amounts of hydrocarbon gases; where the beds are thinly covered or are covered only by previous rocks like sandstone, or the cover is much broken by fault planes extending to the surface, then the gas has escaped. Generally, the more deeply buried the coal beds, the further advanced is the coal from the lignitic stage; also the larger will be the volumes of the residual gas—methane—contained in the strata, and furthermore the greater the pressure under which the gases are confined. In Great Britain, in deep boreholes from the surface to the coal beds, the pressure of gas attained 500 lb. and at Belgian mines 657 lb. per square inch. Great outbursts of methane (chiefly) have occurred in the deep Belgian mines, in one of which many years ago about 140 men were smothered, the gas taking fire at the surface and burning for a day or two. Several hundred other outbursts have occurred in Belgian mines, causing many deaths of miners; being accompanied by the dislodgment of quantities of coal blown out in large part as dust. The great outbursts of methane which occurred on several occasions in the Morrissey mines in the Crowsnest coal field have been unparalleled except by the Belgian outbursts.

One method of protecting men from gas outbursts is to keep boreholes in advance. This is the method practiced in many mining districts of the world, but hitherto it has been argued that it would not permit the advance discovery of a stored pocket of gas such as was encountered by the Carbonado mines. It is Mr. Rice's judgment that if a sufficient number of boreholes be drilled, spreading fan-shaped from the main advance entries, that these would approach near enough to such a pocket of gas and crushed coal to show by the gas flow from the pipe that there was a dangerous area ahead; until this area had been drained by other boreholes, then the entry or room which developed the gaseous territory should be stopped. The matter of gas flows and outbursts, although not so immediately acute in the operation of the Coal Creek mines as that of "bumps," yet is a most serious and vital consideration in planning for future operations in the mines of the Crowsnest field.

While the consequences of the outbursts of gas in the Crowsnest coal field have been most serious, still the "bumps" common to this section have occasioned far more alarm and the destruction of property due to this cause has been greater; it was due to fortunate circumstances that serious loss of life did not attend the most serious "bump," which occurred at a time when the miners were not in the Coal Creek mine. "Bumps" are not related to gas outbursts but they may occur, as in the State of Washington and in Great Britain, where the overlying rocks are rigid and there is great weight of cover; coupled with these conditions may be incor-

rect mining in which too much coal has been extracted in advance and the robbing of pillars has not been conducted so as to bring about proper breaks in the overlying rock. They are believed to be caused by the subsidence of the roof directly over the coal in certain areas under rigid rocks, leaving a great unsupported span of rock stratum. In time this inflexible layer of rock gives way and there is profound rock movement resulting in earth vibrations—on a sufficiently large scale it would be called an earthquake. When one of these extensive movements takes place it means a blow of thousands of tons of rock on the immediate roof of the mine, breaking timber, causing extensive falls in the mine and sending rock tremors through the strata. The history of the Coal Creek mines of the Crowsnest Pass Coal Co. shows several periods during which "bumps" predominated. During the years 1906 and 1908 a series of "bumps" occurred in the No. 2 mine at Coal Creek. In January, 1907, the first loss of life took place here through this cause; after that other "bumps" occurred of increasing intensity until in July, 1908, four men were killed and 20 others, temporarily entombed, narrowly escaped suffocation from gas. No similar disaster took place at these mines until the nights of Nov. 7 and 8, 1916, when three bumps occurred, the first two somewhat local in effect but the third of tremendous force which broke down timber and shook down falls of roof through a large part of the active mine workings. It caused earth tremors which were felt for miles, not only in Fernie, five miles away, but also in other towns to the north and south of Fernie. In spite of the intensity of the "bumps" only one man was killed and that death resulted from the second disaster. Several men were badly bruised in the third great "bump," and some of the escapes of the men in the mine were almost miraculous on account of the great area of roof which had fallen. Had this great "bump" occurred during the day shift, the loss of life must have been great, as areas in the rooms and entries through the most active working section, aggregating thousands of feet in length, were heavily caved. A fourth, milder and more local "bump" occurred on No. 13, 1916, and one of considerable severity on Jan. 12, 1917.

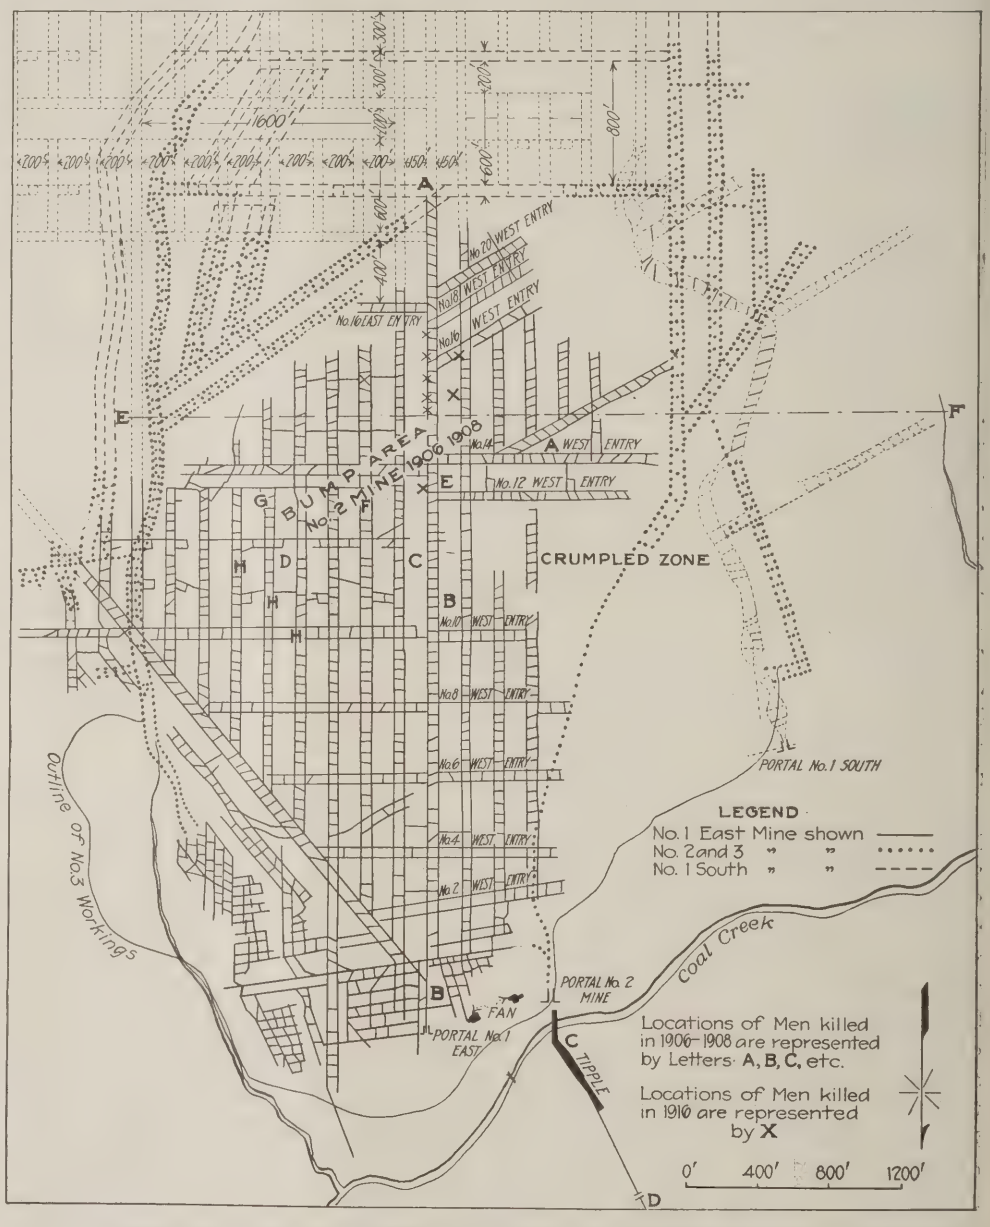

FIG. 2. MINE MAP OF COAL CREEK COLLIERY, CROWSNEST PASS COAL COMPANY

As a result of the "bumps" of November, 1916, a thorough investigation of the whole matter was undertaken and a report made by Mr. Rice, of the United States Bureau of Mines. A better understanding of the situation at the Coal Creek mines can be obtained from a brief description of the workings and referring to the mine map, Fig. 2, and sections Figs. 3 and 4. The No. 2 seam at Coal Creek was opened first and mined extensively in the old No. 2 and No. 3 mines on the south side of the creek. The coal varied in thickness from 4½ ft. on the dip or east side of No. 3 mine to 11 ft. on the west side of No. 2 south. On the west side there is a crumpled zone in which the coal in places is 20 ft. or more thick, but it is crushed and dirty. Throughout the inner central portion of the No. 2 mine, affected by "bumps" and now closed off, the coal is said to have been 4½ to 5 ft. thick. The general method of mining in the Nos. 2 and 3 mines was by the pillar-and-stall system, the stalls or rooms being turned off water-level entries which were driven from inclines. The entries were 12 ft. wide and the rooms 16 to 20 ft. wide with a 40-ft. pillar. The workings were extremely irregular. In some places longwall mining was

started in irregular panels; in other places the pillars were withdrawn. In the "bump" area 50 to 60 per cent. of the coal had been mined out; this correspondingly increased the load on the pillars, which bore the weight of 2000 ft. of cover. This area of disturbance includes a section of about 1000 x 1500 ft., or a territory of some 35 acres in extent. Following the shutting up of this "bump" area in No. 2 south mine, the work in this seam was continued only in the east and west portions. In these later developments, large 150-ft. pillars were left between each pair of rooms; between the two rooms comprising the pair there was a 50-ft. pillar.

The No. 1 seam overlying these old workings runs from 9 to 12 ft. thick; it was developed over the west part of old No. 2 mine by what is termed the No. 1 south mine; subsequently No. 1 east mine was developed over the central part of old No. 2 mine. The No. 1 east mine was the only mine systematically planned of all the Coal Creek workings, and the advance plan was rigidly adhered to. The main entries run due south,

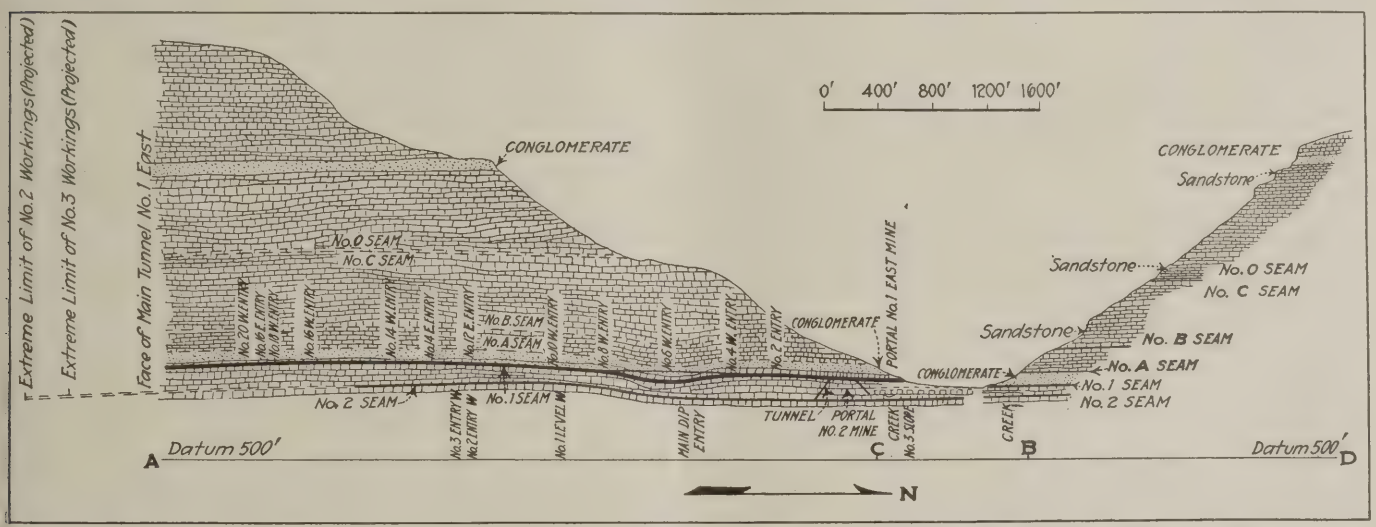

FIG. 3. GEOLOGICAL SECTIONS AT COAL CREEK COLLIERY. SECTION A-B ON LINE OF NO. 1 EAST ENTRY. SECTION C-D SHOWS GEOLOGICAL FORMATION ON THE NORTH SIDE OF COAL CREEK

which is approximately on the strike of the bed; the pairs of cross entries were turned off the main every 600 ft. at the start and in the inner part of the mine every 1000 ft.; there is a 60-ft. pillar between each entry of the pair. Rooms only 14 ft. wide are also driven in pairs and parallel to the main entries; each one of the pair is 60 ft. apart. There is a 150-ft. pillar between each pair of rooms. Only 25 per cent. of the coal was taken out by this method on the advance and no pillars were to be drawn until the mine was retreating as a whole. The method of timbering the rooms in these workings is shown in Fig. 5.

The No. 1 east mine developed rapidly; the mining conditions were good except the immediate top, consisting of the rash and soft coal, which after a time was allowed to fall. The timbering was then carried up to the main roof. The mine passed over the "bump" area of old No. 2 mine without noticeable effect; by November, 1916, the rooms to the east of the main entries were 300 to 400 ft. beyond the abandoned No. 2 mine, and the main entries were about 700 ft. in advance of the No. 2 mine workings or some 5000 ft. from the mine mouth. These were the conditions which prevailed on Nov. 7 and 8, 1916, when the "bumps" occurred which were recorded earlier in the report, and which led to the investigation noted. As already implied, "bumps" are manifestations of pressure and occur only when the mines are at great depth, usually exceeding 1000 ft. If these overlying measures are soft and pliable, such as shale beds, "bumps" will not occur. "Bumps" only take place when there are beds of massive and rigid rock of great thickness above, such as strata of sandstone, conglomerate and limestone.

In commenting further and more in detail on the cause of "bumps," Mr. Rice stated that when an area in a coal bed has been mined out or when a squeeze has occurred so that a subsidence or separation of the immediately overlying softer rocks from the upper rigid rocks has occurred, then the massive stratum will span the subsidence. If the diameter of this subsided area is small, a strong stratum would easily be self-supporting; but if the subsidence of the lower measures was several hundred or a thousand feet in diameter, so that the under side of the massive rock was not supported over this space, then it is improbable that such conditions would continue. In time the massive rock, bearing the weight of the mountain, would fall, giving a blow of tremendous force and produce the effect called a "bump." The larger and heavier the stratum the greater would be the "bump." Above such a great fallen slab there would in all probability be almost the same depth of space as was represented by the subsidence, and there would be a flat dome-like arch as before. After one rigid stratum has given way in the interior of the measures there is opportunity for similar giving way of successively higher strata with less and less effect on the mine workings as the spaces become more or less filled with broken rock and the blow cushioned, also as the vertical distance above the workings becomes greater with each successive fall. If the subsidence of the lower measures continued through enlargement of the area of mining or of squeeze, then the second "bump" might be more serious than the first. In the case of the Coal Creek workings such aggravated conditions may have been brought about by the opening of the overlying or No. 1 seam.

The direct blow of the "bump" on the mine roof may

break timbers, throw down great amounts of soft roof material and cause slabbing of all the coal; or where the coal is strong and the floor weak there may be a sudden heaving or uplifting of the floor. The latter effect was the chief characteristic of the "bumps" which occurred in No. 2 mine from 1906 to 1908, whereas in the recent "bumps" in the upper bed of No. 1 mine the chief manifestation was through the breaking of timber and the release of the soft rash and coal above it. The great danger to the workmen is in being buried by the material, which in the case of No. 1 mine lies above the usual timbering, or from the sudden thrusting up of the floor against the roof or side as was the case in No. 2 mine. In the latter mine the giving off of large amounts of gas was an additional danger. Another secondary but dangerous condition for the men in the area affected was in the greater No. 1 mine "bumps" recently, due to falls of roof which suddenly checked the air current. This sudden arrest of a large volume of air caused the bursting in of many wood stoppings and brought about a momentary pressure which hurled the men in its path in reverse direction to the former current.

"Bumps" are known in other coal-mining districts of the world. They have been a serious menace in a certain South Staffordshire coal mine in Great Britain working the "10-yard" seam, which is 24 to 30 ft. thick. This mine is worked by a square chamber system and, the pillars being quite high, there is probably a subsidence of the immediate roof, opening an equivalent space at some unknown distance above. The strong massive strata higher up which are no longer able to span such areas of subsidence break and cause "bumps." In these mines in such cases the timber is broken down, the coal slabs off and accidents result to the miners. The South Staffordshire workings are 1500 ft. or more below the surface. "Bumps" in coal mines are known in various coal-mining districts of the world and are akin to air blasts in metal mines, which are of such serious account in the deep mines of the Rand and in the Lake Superior copper district.

From the evidence obtained in the investigation leading up to this report the following conclusions are noted: It is believed that had the massive rock strata, found in the rock overlying the coal seams, been frequently broken in mining (in No. 2 mine) from the outcrop then "bumps" would not have occurred. One piece of supporting evidence for this belief is that on the north side of Coal Creek, where the coal is mined by longwall, the cover was broken over the mine for a height of 1200 ft. vertically without causing any "bump" effects.

It is also believed that if the advance mining had been as systematic in the first mines opened up in the lower seam as at present, and coal had not been removed to exceed 25 per cent., then the weight thrown on the pillars would not have been great enough to have caused their being crushed into the floor and probably the "bumps" of 1907-8 would not have occurred. Furthermore, it is believed that the condition of subsidence brought about in the "bump" area of old No. 2 mine is directly responsible for the "bumps" affecting the new No. 1 mine. In other words, had the No. 2 bed been unworked, the "bumps" would not have occurred from the method of mining carried on in No. 1 mine. There did not seem to be any evidence of subsidence in driving the No. 1 entries and rooms. Moreover, in going into undisturbed ground beyond the No. 2 mine subsided area, the danger of further "bumps" would be reduced to a minimum, provided from 75 to 80 per cent. of coal be left intact and the pillars be left undisturbed until the mine is retreating.

After conditions in the Crowsnest coal field had been thoroughly investigated, a conference of local and district mining officials developed a future remedy for "bumps" as shown by the dotted lines in the plan of the mine workings, Fig. 2. Under this system less than 15 per cent. of the coal will be taken out on the advance. For the protection of the employees in No. 1 mine, the rash and roof coal is to be taken down to a point as near the face as practicable; by taking this precaution, it is not probable that should a "bump" occur any one would be injured. The method of mining out the roof coal in advance of the main seam and the necessary timber required is shown in Fig. 5. In this sketch is shown a plan which is recommended for trial; the numbered blocks (dotted) of coal and rash are indicated in the order of their extraction. In this plan an attempt is made to avoid mixing the coal and the rash, as the addition of the latter impurity to the coal would seriously damage the coke.

A problem of great importance in working the coal beds in the Crowsnest field is that of adequately taking care of the large quantities of gas met with; this applies especially to the future developments under deeper cover and at greater distances from the outcrop. Very wisely the mines are not allowed to equip with elec-

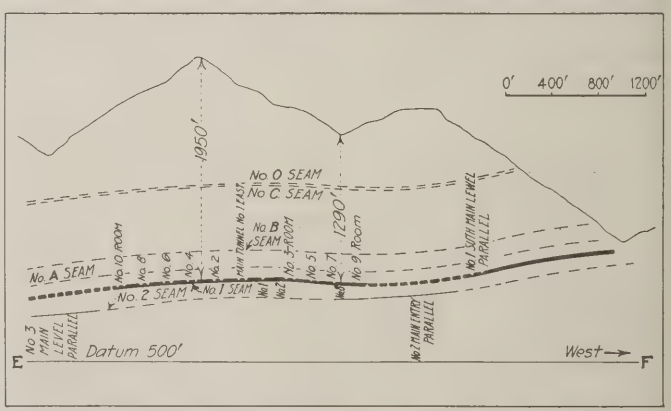

FIG. 4. GEOLOGICAL SECTION AT COAL CREEK COLLIERY ON LINE E-F (FIG. 2)

tricity for haulage or lighting, as the danger is too great.

The following important facts developed during the investigation of these mines: The flow of gas as measured by the analysis of the air in the returns and the outbursts of gas which occurred at the Morrissey collieries show that the Crowsnest Pass coal field mines are among the most gaseous in the world. Gas in these mines is derived from two sources—that stored in the crevices and joint planes of rock and coal; and that occluded or the gas held in the pores or cells of the coal. An unusual condition has been found in testing the amount and kind of gas given off by the broken coal, which shows that an unusual quantity of hydrocarbon gas is given off by the coal on grinding fine

in vacuo, and that three times as much ethane and other hydrocarbons are given off as methane under these conditions.

The following recommendations are made regarding gas flows: Since the gas pressures rapidly lessen from about 18 lb. at a distance of 21 ft. from the face to nothing at the face of the coal, it is indicative of the importance of draining the coal measures by advance headings. Drill holes should be kept in advance of the main heading and in faulty ground, and such entries

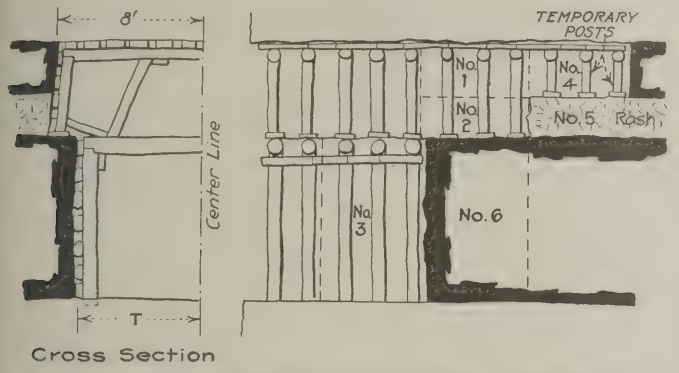

FIG. 5. SECTIONS SHOWING PROPOSED METHOD OF MINING AT COAL CREEK COLLIERY

should be advanced at only a moderate rate in order to permit the slow draining of the gas. In those portions of the field which permit of mining by the longwall advancing system, this method should be used from the outcrop. Longwall would probably drain off the gas more slowly and safely than pillar-and-stall work. This system could probably be applied to the mining of the No. 2 bed.

It was found in this investigation that there are obscure matters which can only be cleared up by further investigation. The recommendations for such investigation by a commission are as follows: (1) The carrying on of experimental methods of mining the coal, especially in No. 1 bed, so as to lessen the danger in the case of "bumps" and to look into the best method of timbering. (2) To determine the amount of occluded gas in the different coal beds, how it is held—if there is any chemical instability which might be connected with any shrinkage of the coal in pillars. In this connection plugs or monuments in the roof, ribs and floor might be established at various points in the mine to determine whether movement or shrinkage is going on. (3) In the matter of protection from firedamp, to continue the gathering of samples of mine air and to obtain data on the drainage of gases from the coal beds both when the mine is working and when it is idle. (4) To drill a number of long boreholes in advance of the working faces to determine the amount of gas given off and to record the gas pressure at regular intervals from the inner end of the hole to its mouth. This information should determine the rate at which the entries should be allowed to advance. (5) The greatest function of this commission would be to determine how the mines in this field should be laid out so that all the coal may ultimately be obtained. It seems to be impracticable to sink shafts in the larger part of the field, and if the coal has to be attacked from the outcrop, then it will take entries six, eight or even ten miles in length to mine the interior of the field. (6) It is recommended that an advisory commission be created to confer with the officials of the province and that it be made up of men of authority on scientific and technical matters, including a geologist, a mining engineer, a chemist and an experienced mine operator.

Minecdotes

A Dud?

One day while making an inspection of some of his working places, the inside foreman had a rather exciting though somewhat amusing experience. The place pitched about 70 deg., and after calling up to the men who were apparently at the face, and being assured that everything was all right, he proceeded to climb up the manway. He passed the first crosscut, and when about midway between that and the next one above, he was somewhat startled to look up and see the stolid face of the miner peering down at him saying, "Better watchen, Mr. Boss, one hole he no go off yet."

Some Man

An old man who had picked on the breaker platform for a great number of years at a mine where the coal was all hand loaded, had the surprise of his life when some stripping coal, loaded by a steam shovel, was dumped on the table.

A new stripping had been started, and without his knowledge the shovel loaded its first trip this day. The big lumps of coal passed down the table, each time accompanied by a bulging of eyes and a shaking of his head on the picker's part.

Finally the platform boss could contain himself no longer over Steve's strange actions, so he asked him what was the matter.

"Oh," said Steve with a deep sigh and a great shrug of his shoulders, "I work this place long time, I never see big ones like come today. By gee, must be strong man some place."

A Fast Day for the Driver

At a certain mine there is a traveling way for both men and mules. At one place in it the top is about 6 ft. high. Very often the drivers would ride up on one of their mules and when coming to this low spot lean forward along the mule's neck and pass under without a mishap. But this day the unexpected happened, the driver and the mule became wedged fast.

It was of course a rather ticklish although ludicrous predicament. Just how to get them free without physical injury to either was the question. The driver's yells and squirmings only increased the mule's restlessness. The beast was not of the circus variety, so would not lie down when asked; and, with the small amount of space in which to work, it was quite a problem.

Along comes John Hunk. He blankly took in the situation, sort of sniffed at the men being at a loss as to what to do, and said, "I fixen." He strode away to come back shortly with an ax. He walked up to the mule and was just restrained in time from cutting off the mule's legs.

* * *

It might be added that the man was safely rescued by using a lever across the mule's back.

British Columbia International Mining Convention

By Robert Dunn
Mines Department, Victoria, B. C.

HOW can present coal-mining operations in the Pacific Northwest be so improved as to obtain better commercial results in disposing of the product? Generally speaking, this was the question most to the fore in discussion affecting the coal-mining industry at the International Mining Convention held at Vancouver, B. C., from Mar. 17 to 19. The speakers were G. W. Evans, coal mining engineer, U. S. Bureau of Mines, Seattle, and Francis W. Glover, manager of the Princeton Coal and Land Co., Princeton, B. C.

Mr. Evans' paper contained valuable information to operators and was much appreciated. Emphasizing the constantly growing necessity of placing the smaller sizes of coal on the market in such shape that they will satisfy the trade because less of the lump coal is being mined and because present conditions in this respect are bound to become accentuated, he referred to the problem of the utilization of much that heretofore has been considered waste in the form of powdered fuel. Dealing with the latter development, he told of plants installed in various parts of the northwest, and particularly in the City of Seattle, which were equipped for the use of this fuel for heating purposes and were obtaining satisfaction therefrom.

In this connection the coal-mining delegates were afterward given ocular proof of what can be accomplished in this direction by witnessing the powdered fuel plant recently set up at the factory of the British Columbia Sugar Refining Co., Vancouver, B. C., in operation. The new furnace, which supersedes one designed for oil consumption, had been in operation for just two days prior to the demonstration. The interested visitors were informed that up to the present the installation has given entire satisfaction. The fuel in use was being obtained from a Vancouver Island colliery. It was waste coal which had been submerged for seven or eight years and, until very recently, never considered as an asset owing to its high ash content, running between 26 and 30 per cent. in ash. After being pulverized, however, no difficulty was experienced in respect of combustion in the furnaces with which the sugar refinery is provided. The expectation was that it would prove just as satisfactory as the oil and more economical.

Mr. Glover's address was more local in its application. He advised Government supervision of coal-mining operations to the end that wasteful methods in extraction of coal might be prevented. The practice of speculators acquiring coal lands and holding them for high prices was deplored. There should be more of the spirit of coöperation between employer and employee, the former making it his business to see that working conditions, both as to safety and convenience, were of the best, and the latter undertaking to see that all miners gave the best that was in them while at work.

Complimenting the collieries of the Province on their good work during the four years of the war, Hon. William Sloan, Minister of Mines, in opening the convention said: "I wish further to congratulate the collieries on the splendid effort they made during the war to meet the urgent need which we, and the empire as a whole, has for their product. Both the operators and the miners are to be felicitated on the plucky manner in which they stuck to their guns. They have the satisfaction of knowing that they did their bit and I would have them understand that their work is appreciated." He pointed to the production of 1918, the outputs of both coal and coke exceeding 1917 figures; the increased production of coal being some 142,093 tons, while that of coke was 30,751 tons. As the value of coal had advanced substantially, the product of the coal mines during 1918 represented about $12,794,932, an increase over 1917 of $4,310,599.

Addresses were given by the different Government mining engineers, W. M. Brewer referring to the coal-mining development of Vancouver Island; R. W. Thomson touching on operations in the Nicola District; P. B. Freeland dealing with the promising bituminous fields of the Princeton section; while J. D. Galloway briefly described coal-mining operations in the Twelkwa section on the line of the Grand Trunk Pacific Ry., and predicted the opening up of more good mines when this country is further prospected.

A digest of the address made by G W. Evans, of the United States Bureau of Mines, which was referred to in the opening paragraphs of this account, is given in the following:

Better Preparation and Utilization of Coal

G. W. EVANS, coal mining engineer, Northwest Experiment Station, U. S. Bureau of Mines, Seattle, stated at the outset that his remarks would not be specifically with regard to the bituminous coal of British Columbia. As, however, the coal of this character in the State of Washington was similar to that of this Province, the problems confronting the people of the two countries in this respect also were similar. His plea was for the greater use of the smaller sizes of coal, largely disregarded by both producer and consumer. Coal operators in both British Columbia and Washington knew that the percentage of large sizes was decreasing and the quantity of small coal was increasing. This change, he said, had been brought about partly by the inferior class of coal miners of now compared with former years.

Today some of the coal miners, particularly in the State of Washington, knew only how to drill a hole and fire a shot; some did not know even how much powder should be used. The result was that the coal is shot into small pieces, and in steeply pitching coal beds the coal is further broken up by falling down the chutes. It was therefore necessary to face the inevitable fact that the percentage of lump coal will decrease and the small sizes are going to increase as time goes on unless new coal fields are discovered. It behooved us, for these reasons, to make preparations to save more of these smaller sizes and offer them to the public in the cleanest possible condition. To separate impurities

from the coal in the smaller sizes was a more difficult matter than to clean the coal of larger size. In the anthracite coal fields of Pennsylvania dry cleaners were used for the smaller sizes and, at one bituminous mine in the State of Washington, a spiral separator was tried with only partial success.

It has been found, the speaker asserted, after years of experimenting that treating the coal in a liquid, thus taking advantage of the difference in specific gravities between the coal and its associated impurities, is the only practical way of making a proper separation. Experience, he said, has taught that, in order to get the best results in the washing of coal, the washer should be of proper design, properly adjusted and operated. He had seen plants where tubs appeared to do pretty good work, but for a new plant would not recommend the tub except in an emergency.

Mr. Evans proceeded then to describe some of the coal-washing plants that are now being built, and after describing the various methods of their operation declared that to get the best results a thorough study should be made of the coal to be washed and the type of jig installed that would best suit the purpose. Such studies and designs should be by someone competent to make such investigations. He did not advise ordering from a catalog, suggesting that the operator should take his coal-washing problem to a specialist and ask for a guarantee so that the resultant product would measure up to certain specifications. In this connection he said, "Our coal-washing plants are being built with more refinements each year, in order to successfully meet the requirements exacted by more complex coal and an effort to practice true conservation."

Jigs Require Careful Attention

Mr. Evans recommended that operators should pay more attention to the efficient operation of their jigs. Very few could tell what results they were getting, and little did many of them realize that the amount of good coal going to waste or the percentage of absolute waste in the wash product can be determined by a proper study with a "float-and-sink" machine, and the necessary corrections made in the jig.

Briefly outlining the manner in which this work is done, he said: "Samples are taken every 30 minutes for a period of eight hours at different parts of the plant. Careful head samples are taken of the material going into the washery; also samples are taken at each of the refuse discharge gates of the machine, and as the washed product passes over the conveyor from the jig it too is carefully sampled. Next day each of these samples should be treated about as follows: The original samples should be coned and quartered—care being taken not to break the particles in the sample—until a representative sample of about 40 or 50 lb. is obtained. This smaller sample is further quartered until the required size sample is secured, which is to be used in the 'float-and-sink' machine. The machine is then filled to the required height with a solution of zinc chloride of the proper density.

"This particular density is called the 'permissible bath' for the coal under consideration, and might range from 1.35 to 1.65 specific gravity, depending on the amount of adherent ash in the coal and the amount of ash the coal market will assimilate. The head sample is then run through the machine. The marketable product will float and the refuse will sink. Each part is weighed and in this manner the percentages of each are determined. The results obtained on the head sample indicate what the washers should produce if they are working at an efficiency of 100 per cent.

Percentage of Coal Wasted

"The 'float-and-sink' machine, by the way, is assumed to be a 100 per cent. efficient separating machine. The refuse is treated in the same bath, and if the washer is doing perfect work, there will be no float; and in treating the product there should be no sink. This seldom happens. The percentage of float in the refuse and the percentage of sink in the product are used as factors in determining the efficiency of the coal washer. By making these determinations adjustments of the length of stroke of the jigs and experiments with the sizes to be treated to get the desired results can be made. The man who operates the jigs will more clearly understand what is required of him and the machine he is paid to operate."

Quoting from a bulletin published by the Commission of Conservation of Canada on the conservation of coal in 1914, Mr. Evans enumerated the equipment of which the principal collieries of British Columbia were provided in respective washers at that time. He pointed out that the same authority estimated that the cleaning losses are as follows: Hosmer mine, no loss because small size is coked; Nicola Valley Coal and Coke Co., no estimate; at the Western Fuel Co.'s mine the sludge and other unmarketable coal is used under the company's boilers, and in the Northfield mine of the same company it is estimated that the sludge loss is 2 per cent.; at the Vancouver Nanaimo Co.'s plant the coal less than ¼ in. was wasted; no estimate was made as to the amount. There is 15 per cent. of the output of the Fiddick mine of the Pacific Coal Mines, Ltd., that is wasted; at the Extension colliery of the Canadian Colliery Co. it is estimated that about 34 per cent. is wasted in bone and slack, and at the Union washery of the same company there is a waste of 24 per cent.

"Of course, these percentages," Mr. Evans said, "do not all represent clean coal; but it is safe to assume that between 5 and 10 per cent. greater recovery could be made in treating the Nicola Valley and Vancouver Island coal if crushers were used on the larger impurities, such as bone and coal and coal and shale from the picking tables and the middlings from the jigs, and the crushed material either treated on tables or in jigs; and if the bird's-eye or sludge now being wasted were treated on properly designed tables. These are features well worth considering carefully. A 7 per cent. saving on the coals for these two fields would probably equal 140,000 tons, which in itself is worthy of an effort."

At one plant in the State of Washington using a well known jig, Mr. Evans stated he personally saw 80 lb. of white rock picked from seven tons of coal that was supposed to have been cleaned by that jig, yet the company, which was paying a man good wages to attend to the jig, wondered why the people of Seattle complain at the amount of impurities in the coal. Let us have more study and education along this line, he said.

Until recently we were satisfied to let the refuse from the jigs go to the waste dump without further thought, he continued; today many of the progressive companies are crushing some of the refuse and all the middlings, and treating them either in another jig or on properly designed tables.

Also until within the past few years little thought was given to the waste water and smaller sizes, usually called bird's-eye or sludge, but at present in some plants the waste water along with its load of small coal and associated impurities is conveyed to a settling tank and from the settling tank is fed to properly designed concentrating tables. The tables generally used are what might be called nephews of the old Wilfley table, familiar to ore-dressing engineers. As a rule the riffles used are higher and the surface of the table is differently arranged.

Efficient Plant Wastes Nothing

A coal-cleaning plant operating along most modern lines does not waste very much except the color in the water. Probably some enterprising engineer will attempt to recover the color by means of an Oliver filter.

Mr. Evans stated that coal operators might ask what was the use of all this refinement in coal preparation and saving of small sizes when they were unable to dispose of one-half the small coal on hand. This led him to the second part of his paper under the heading, "The Better Utilization of the Small Products from the Washers." He said that the product of such a field as that of the Crow's Nest gave rise to no problem because the smaller sizes can readily be used in making coke. It was different, however, with noncoking, bituminous and sub-bituminous coals.

Continuing, he said, "In many of the large steam plants mechanical stokers of some form are in successful operation. They burn the small sizes efficiently with little or no smoke given off. The ash formed is disposed of mechanically. In fact everything goes along pretty well in a large plant, but only the larger plants can afford to install mechanical stokers. In the smaller

plants where the installation of large stokers is not justified because of the expense, the boilers usually are fired by hand. In plants where the expense of installing large mechanical stokers is not justified or even where justified in some instances, powdered coal equipment is now being installed. Today we find that pulverized coal is being used in many steam and heating plants of some cities. Several large buildings in Seattle have recently replaced California fuel oil with powdered coal and, according to the statements of the engineers in charge of those plants, they like the powdered coal best."

The speaker proceeded to enumerate some of the powdered-coal installations in the State of Washington, mentioning the Western Avenue plant of Seattle, the Puget Sound Traction Light and Power Co., and describing equipment. The coal was ground so that 95 per cent. of it will pass a 100 mesh screen. Renton buckwheat and bird's-eye or sludge is used. "In this connection," Mr. Evans stated, "it might be well to mention the fact that at the Renton coal mine the company years ago was forced to dike the bird's-eye and not allow it to go into the streams with the waste water because of protest from the neighboring farmers. Today they are loading coal from the pile of 160,000 tons saved by means of a drag scraper and utilizing it in their Seattle powdered coal plant. This is a plan that others might follow to their advantage."

Other installations mentioned were the Superior Portland Cement Co.'s plant at Concrete, Wash.; that at Briquettville, Wash., where the powdered coal used in some of Seattle's largest buildings is pulverized; that of the Pacific Coal Co. at the Black Diamond coal mine. At Black Diamond, he said, the smallest sizes of the Black Diamond coal is used which is non-coking bituminous; at the Coal Creek plant of the same firm they were using the smallest sizes of the subbituminous coal of the Coal Creek mine; at Briquettville they were using a mixture of Black Diamond-Coal Creek and the coking bituminous coal of the Burnett mine.

The following well-known buildings of Seattle, it was stated, are using powdered coal: The Seattle Natatorium, or Crystal Pool; New Richmond Hotel; Broadway High School and the 42-story L. C. Smith building. The air pressures used at these plants ranged from 2 to 3 lb., and the pulverized coal was hauled to Seattle in five-ton air-tight tanks from Briquettville, a distance of 12 miles.

Mr. Evans followed with some notes taken from a detailed report of a 24-hour test made during February, 1919, on a Babcock & Wilcox boiler of 600 hp., which during the test had a rating of 125 per cent. Without going into details he quoted a few of the economic and efficiency results obtained:

Water fed per pound of coal fired	8.50 lb.
Water evaporated per pound of dry coal	8.35
Equivalent evaporation from and at 212 deg. F. per pound of combustible	11.30
Calorific value of one pound of dry coal	11,660 B.t.u.
Calorific value of one pound of combustible coal	13,700 B.t.u.
Efficiency based on coal fired	78.95 per cent.
Efficiency based on combustible	60.05 per cent.

Continuing, Mr. Evans said that there was quite an accumulation of slag on the sloping sides of the furnace which is removed at intervals of one to two months when it has accumulated to a thickness of 6 to 12 in. The ash accumulated in the boiler tube was removed by the aid of a soot blower. The condition of smoke was light; there was no backlash; the effect on the brickwork was not noticeable; there was no pulsation and it was the opinion of the engineer who made the test that the results were satisfactory. The coal used was screenings from the Issaquah mine of the Pacific Coast Coal Co., which is sub-bituminous.

Dealing with comparative costs of fuel oil operation versus powdered coal, Mr. Evans quoted some observations by C. F. Harrington, mechanical engineer, on the use of powdered coal. After giving statistics the speaker pointed out that the conclusion was that, with fuel oil at $2 per barrel and washed bird's-eye coal at $2.50 per ton, there is a marked saving in favor of powdered coal.

Comparing powdered coal with fuel oil Mr. Evans pointed to the analyses of some Western coals. These show that they average 10,000 B.t.u. per pound—that is, figuring conservatively, 20,000,000 B.t.u. per ton. If California fuel oil averages 18,500 B.t.u. per pound and 7.8 lb. to the gallon, 42 gal. to the barrel, we would have 6,000,000 and 60,600 B.t.u. to the barrel. It takes therefore approximately 3⅓ barrels of oil to the ton of coal. The oil would have to be sold at 80c. per barrel to be on a parity with coal at $3 per ton. With fuel oil at $2 per barrel, one could afford to pay $6.66 per ton for the coal except the cost of handling the ash, which is not great. There is no smoke given out by the stacks of these smokers when they are operated properly.

Concluding, the speaker said: "By definite teamwork on the part of the coal producers, the coal salesmen, the fuel engineers and the public a large percentage of the small coal now being wasted can be saved to the coal companies and the state or province. Such teamwork will be a factor in successfully overcoming the inroads made into fuel markets of the northwest by California fuel oil and cause this same oil to be utilized along lines where it will do the greatest amount of good. The oil supply of the world is limited and should be conserved. The supply of coal in the Province of British Columbia and the State of Washington, not to consider the coals of Oregon and California, are sufficient to last the needs of the Pacific Coast states for hundreds of years, and why not utilize these coals to the best advantage? By practicing true conservation we will make the supply last longer, and the consumer will be able to buy a better grade of coal at a cheaper price.

Francis Glover, of the Princeton Coal and Land Co., Princeton, B. C., in dealing with the better utilization of British Columbia coal suggested that the Government should introduce legislation preventing the coal lands falling into the hands of speculators whose one idea was to hold them in order to sell at a profit. Engineers, he said, should be appointed by the Government to see that coal was not extracted by wasteful methods. As to operators, he declared that they should realize that all conditions relative to the human element should be of the best. By this he meant safety conditions, living conditions and working conditions. They ought to have the most up-to-date machinery and tackle, and should be ready at all times to work in harmony with labor, referring disputes to the Government Board of Control and abiding by the decisions. On their part the laborer should realize that production is imperative to the success of the coal industry.

He spoke of the necessity of the railways providing the best transportation facilities possible, and expressed the opinion that in the past one of the great drawbacks to the profitable mining of coal in British Columbia has been the intermittent tonnage. By this he meant periods of slackness and periods of great activity. This led, during the slack period, to the deterioration of workings and roadways, and had the effect also during the periods of great activity of tempting operators to attain a fictitiously high output by following the line of least resistance and neglecting development work.

In speaking of the present methods of burning coal, Mr. Glover termed them a disgrace and thought that there should be some effort at an educational campaign that would result in the practice of economy by the general public. He also dealt in a general way with the problem of utilization of the many valuable by-products of coal.

Of the 500 odd delegates, between 25 and 30 were representatives of the coal industry. Some of the latter were Mr. Evans, already referred to; D. C. Botting, Commissioner of Washington State Coal Operators Association; Professor Landis and Dean Roberts, of the University of Washington; George Wilkinson, Chief Inspector of Mines for British Columbia; Ralph Smith, vice-president of the Pacific Coast Coal Company;

S. H. Greene, superintendent of the same company; John Ryczeh, sales manager of the Roslyn Cascade Coal Co., Roslyn, Wash.; G. E. Rockefeller, mining engineer, United States Government; Percy E. Wright; Mr. Knouse; Mr. Bogardus; H. H. Sanderson; G. E. Collins; Mr. Dalby; Mr. Seagraves; F. W. Glover; Donald MacLean, manager of the Coalmont collieries; R. Stirling, Thomas Price and William Walls, engineer, master mechanic and superintendent of diamond drilling respectively for the Canadian Western Fuel Co.; Joseph Daniels, coal geologist, and Dudley Michel, superintendent of first-aid work for the British Columbia Department of Mines; Frank Good, superintendent Carbondale Coal Co.; D. S. Hanley, president Carbon Coal and Clay Co.; Mr. Pearce, general sales manager Carbon Hill Coal Co., and Irving Gard, engineer for Frank Waterhouse Co.

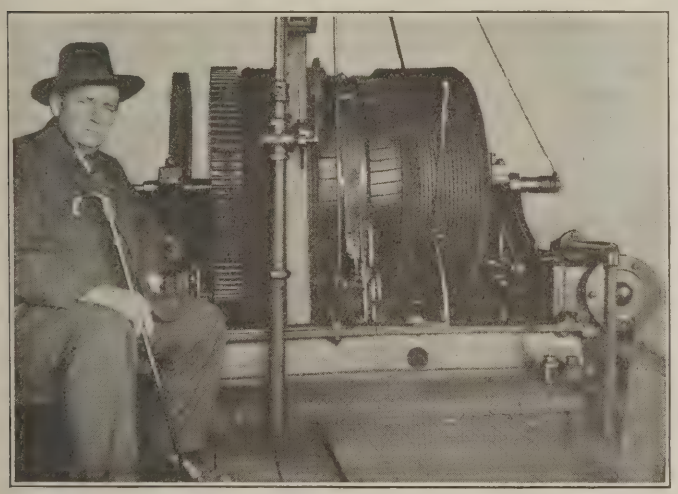
Coal Near Mesa Verde National Park

Fuel is scarce in southwestern Colorado, so the coal found in the vicinity of Mesa Verde National Park is of considerable interest. The coal beds in the park are not at present minable, but those that lie northeast of the park, near Mancos, Colo., could supply a large part of the region west of the San Juan Mountains, which must obtain its coal either from this field or from others farther north. The coal near Mancos is found near the tops of rugged mountains that are cut off from the Mesa by deep canyons and must be lowered down the mountain sides on inclined tramways for shipment. A mine operated in this way on Menefee Mountain, at an altitude of 1100 ft. above Mancos, may be seen from the Rio Grande R.R. at that town.

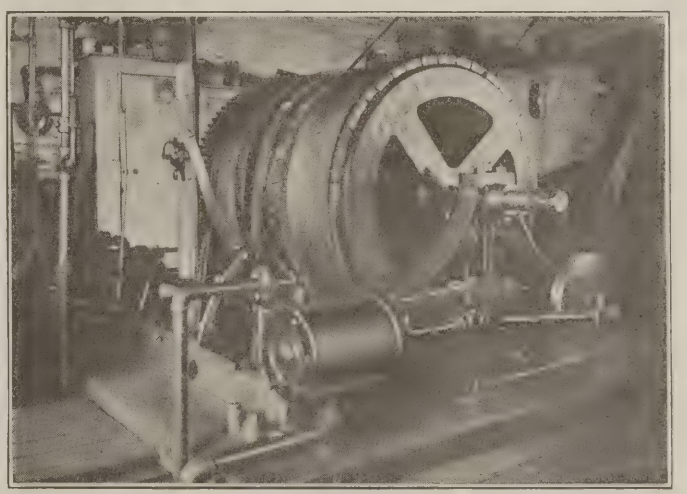
The Mancos field is on the northern edge of a great expanse of land containing coal that ranges from a bituminous coking coal, mined at Durango, Colo., to a high grade sub-bituminous coal mined near Gallup, N. Mex. The coal near Mancos has nearly as great heating value as the coal near Durango and is of nearly the same quality as the coals of southeastern Illinois, western Kentucky, Ohio and southeastern Kansas.

Geologists describe the rocks of these mountains as the Mesa Verde group, which consists of the Point Lookout sandstone at the base, about 300 ft. thick, the Menefee coal-bearing formation in the middle, about 400 ft. thick, and the Cliff House sandstone at the top, about 400 ft. thick. The Point Lookout sandstone was named from Point Lookout, the northernmost point of the Mesa Verde National Park, about 7 miles southwest of Mancos, and the Cliff House sandstone was named from the prehistoric ruins in the park called cliff houses, near which it is most strikingly exposed.

The coal beds are confined to the summits of the mountains and were recently examined at many places by a geologist of the United States Geological Survey. They are very irregular, but at almost every place where the whole section of the coal-bearing formation is exposed, from one to four coal beds, each thick enough to mine, have been found.



A report entitled "Coal South of Mancos, Montezuma County, Colorado," by A. J. Collier, describing the rocks and coal resources of this region, has recently been published by the United States Geological Survey, Department of the Interior, as Bulletin 691-K, and may be had an application to the Director of the Survey.



Handling 2¼ Million Tons in 37 Years

Thirty-seven years of continuous operation is not a bad record for any machine. Such, however, is the record of the mine hoist of the Centerville Block Coal Co., at Centerville, Iowa. This machine is shown in the accompanying illustrations.

The hoist, a single-drum, back-geared Lidgerwood, was purchased and put to work in the early eighties and has been kept in practically continuous daily operation ever since. Alex. Dargavill, superintendent of the mine (shown at the left in one of the photographs), says concerning this machine: "Our company bought this engine in 1882. It has been in continuous operation ever since, hoisting out of a shaft 170 ft. deep at a present rate of 350 tons per day. The unbalanced load at each trip amounts normally to 3000 lb. A careful estimate of the acreage mined out shows that 1¾ million tons of coal has been produced. The dirt and slate removed in driving entries and turning rooms is estimated at another half million tons."

These tonnage figures tell their own story. They show chiefly two things: (a) The engine must have been built and installed right in the first place, and (b) that it has been handled and cared for properly. Engines do not last for any such long term of years unless both of these conditions are fulfilled.

MINE HOIST WHICH HAS SEEN 37 YEARS OF CONTINUOUS SERVICE AT ONE OPERATION

More Light on the Railroad Fuel Situation

Unless the President takes mandatory action, which it is not expected he will do, the efforts at peace-time price-fixing have come to naught. It is generally recognized that it was the coal operators who forced the issue and established conclusively that the Railroad Administration would not be a party to the effort of the Secretary of Commerce to promote business activity by stabilizing prices until the end of the year.

The Industrial Board of the Department of Commerce, which has the matter under its supervision, was not taken seriously at first. Much prestige came to it, however, as the result of the success in obtaining a 10 to 14 per cent. reduction in steel prices. The steel men, apparently, took it for granted that the Government would hold up the hands of its own board, and learned through the coal men that the Railroad Administration would not buy rails at the price agreed upon.

The coal men, having clearly in mind the repudiation of the Peabody committee, called upon the Industrial Board for assurances that the Railroad Administration, the War Department, the Navy Department and the Interior Department would buy coal at the prices agreed upon. Much to the surprise of Chairman Peek, the Railroad Administration insisted upon continuing the purchase of coal in its own way.

The disclosures confirmed the suppositions of the National Coal Association that the railroads are making use of every means in their power to beat down the price of their coal. Tart exchanges took place between Director General Hines and J. D. A. Morrow, general secretary of the National Coal Association. Mr. Morrow declared that the Railroad Administration had returned to "unfair practices which would drive the price of railroad fuel below the cost of production." Mr. Hines retorted by characterizing Mr. Morrow's statement as "interesting fiction," but leaving the inference that the coal operators are conspiring to boost the price to the Government and to the public. This led Mr. Morrow to go into detail as to the practices being resorted to by the Railroad Administration in the purchase of coal. A portion of his statement in this connection follows:

> The United States Railroad Administration claims that its present arrangements in obtaining railroad fuel coal will adequately safeguard the public interest involved. For example, to avoid unduly depressing the prices of coal, the Director General has prohibited the purchasing agents of the various roads from naming prices which the operators must meet to obtain a share of the business, but he permits coal speculators to bid on the railroad business without naming the mines from which the coal is to come, and without having their commitments covered in advance, whereupon these speculators adopt precisely the tactics which he has forbidden his own agents to use.
>
> It is stated that the tonnage will be distributed fairly through permitting the purchasing agent of each railroad to buy his own coal. So far as is known, however, there is no practical provision to prevent the purchasing agents of different railroads from bunching their orders in the same district or in the same mines. Since it is the policy of the Railroad Administration to buy cheaply, it is the inevitable tendency to bunch orders in the low-cost districts and in the low-cost mines. As an illustration, when the Pennsylvania Lines West closed their Pittsburgh district fuel business for the month of April, within the present week, a half dozen operators were given the entire business at low bids, some of which were below the cost of production and were so specified when the bids were sent in. Other operators who have normally shared in this business were deprived of their orders.
>
> In the Hocking Valley district of southern Ohio, railroad fuel orders have been placed with a number of smaller operators producing inferior grades of coal at reduced prices, while the mines which have in previous years regularly supplied this road have been denied participation in the business. In this case the coal now being taken was rejected by the Railroad Administration when tendered to it for locomotive purposes within the past year.
>
> When the Missouri Pacific Ry. arranged for its coal supply recently, the determining factor was the bid submitted by the Western Coal and Mining Co., a subsidiary of the Missouri Pacific Ry. Other operators were given an opportunity to share in the business at the price named by the Western Coal and Mining Co. Even if the price named was above the cost of production, we consider the method employed in this case, and which can be employed in other cases, to be manifestly unfair. It is an old-time method of purchase which resulted in grave abuse.
>
> As evidence of good faith and of fairness to all parties concerned, the coal operators asked that all bids on railroad coal be made public, as is done by every other Government department. This request has been refused, and only information made public as to the price at which the business is finally placed. Despite the Director General's public statement of Feb. 19 that this information would be available to any interested party, it has been refused coal operators and their accredited representatives as late as Mar. 28, on the ground that local representatives of the Railroad Administration have no instructions to give out such information.
>
> In short, the bituminous coal operators have endeavored to obtain the coöperation of the United States Railroad Administration in an effective manner, to deal with a question which they consider of vital interest to the general public. The Industrial Board appears to them to afford a medium by which a practical solution of the difficulties could be obtained with all the rights and interests of the general consumers of coal entirely safeguarded. They are still ready to coöperate with this board and the Director General of Railroads in what seems to them an eminently broad and sensible program to meet an extraordinary condition.

Government Will Record Fluctuations in the Price of Coal

A permanent record of price fluctuations in coal, prior to the war, during the war, and after the signing of the armistice, is to be made by the Government. The work is under the direction of C. E. Lesher, the geologist in charge of coal for the Geological Survey. Commenting on the Peabody prices, Mr. Lesher says:

Whether the reduction in prices effected by the voluntary action of the producers would have satisfied the public and met the needs of the situation never will be known, for no sooner were the results announced than the Secretary of War publicly repudiated the action of the Committee on Coal Production, stating that the prices agreed upon were unwarrantably high.

It is not necessary to pass judgment on the reasonableness of the Peabody prices. That they were higher than necessary to return the cost of production and a moderately fair profit to the producer has been shown clearly by the subsequent investigation of the committee of engineers of the Fuel Administration. The important point is that the Peabody prices were substantially below those prevailing at the time. They were, from their inception, understood to be a temporary stop gap, pending a determination of more exact and proper prices. They were the first and practically only prices representing a reduction, established by an industry as a whole for the benefit of the entire public.

The Peabody prices did not apply to coal sold for export and, as a result, Canadian consumers were able to outbid those in the United States. New England and Canada depend upon the fields in central Pennsylvania for their supply by railroad routes. Under these circumstances, New England consumers were unable to obtain satisfactory deliveries of bituminous coal and induce operators in central Pennsylvania to break away from the Peabody price. Although the Peabody prices were claimed to be exorbitant, the only important divergence from the price resulted from the action of consumers, and was an increase.

The flurry in prices for Clearfield, Somerset and Cambria County coals in the winter of 1915-16 was the first evidence of the impending shortage that became such a feature from October, 1916, to the end of the war. The orders of the Allies for war materials first were placed largely in New England, and the speeding up of industries in that section made the demands for coal from the tributary all-rail fields of eastern Pennsylvania so insistent that spot prices soared to more than double those obtaining a few months previously. Beginning in July in many districts, and by August in all districts, prices started upward in response to a demand the insistence of which was not appreciated at the time. With a suddenness and to an extent unequaled in the history of the bituminous-coal industry, spot prices rose nearly 300 per cent. in six months. In Ohio and Pennsylvania the increase was greater. The highest spot price recorded was more than 400 per cent. above the pre-war level.

Public discontent with the continued high prices was manifested strongly. Notwithstanding that it was the bidding of consumers, one against the other, that was responsible for the high prices to an extent equal to if not greater than the setting of the price by the producer, the producer was held responsible for the condition.

Effective Mar. 15, 1919, embargoes which were in effect since December, 1915, and January, 1916, against coal to Hudson River gateways for reconsignment, have been cancelled, according to a recent announcement issued by G. N. Snider, coal traffic manager of the New York Central R.R. The combination of rates to and beyond these gateways, however, exceed the joint rates from the mines, so if benefit of the joint rate is desired, reconsignment requests must be made to the New York Central R.R. direct, in accordance with Reconsignment Circular C. T. D. 237.

Coal Operators May Recover Part of 1917 Income Tax

Coal producers may be able to recover some of the money they paid to the Government in income taxes in 1917 if they will file with Commissioner Roper of the Internal Revenue Division of the Treasury Department the necessary data to enable the Commissioner to fix the proper basis for the different classification of those engaged in the coal industry, with a view to applying the law in a uniform manner.

The foregoing is the substance of a conference had by W. A. Marshall and Charles S. Allen, president and secretary respectively of the Wholesale Coal Trade Association of New York, with Commissioner Roper in Washington recently, when the subject of unequal assessment of income and excess profits taxes on those in the coal industry was discussed. In substance Mr. Roper said to Mr. Marshall and Mr. Allen:

"I know there are inequalities; I am anxious they should be eliminated and that the tax should be applied uniformly. The facts concerning those inequalities are so diversified that it is impossible for my department to determine them. Therefore I must depend upon your industry to gather the necessary data and submit them to me. When that is done for a substantial part of the industry, I will then fix proper bases for the different classes of those engaged in the industry, with a view to applying the law in a uniform manner."

Investigation shows that there were large sums paid in taxes for 1917 which should and will be refunded when the facts are placed before Mr. Roper, says Mr. Marshall in a Bulletin issued by the Association of which he is president. When these data are placed before the Commissioner the 1918 taxes will then be fixed upon a proper basis.

Mr. Marshall and Mr. Allen have arranged with Gibbs L. Baker, who has looked after the interests of many coal men in Washington during the past year, and with James T. Lloyd, a former Congressman, to take care of the interests of the coal men who are members of the New York Association.

Mr. Baker has discussed the entire matter with Commissioner Roper and says the Commissioner agrees that the present classification of the coal industry is entirely unscientific and unjust, and is anxious to have the coöperation of the industry in trying to reach a satisfactory classification.

As tentative returns for the 1918 tax have been made and an extension of 45 days has been granted to file permanent returns, Mr. Baker says it is absolutely necessary that coal men give the matter immediate attention. Mr. Baker is of the opinion that all the wholesalers should be classified as personal service concerns, not only for 1918, but also for 1917, where no actual investment of capital is involved. "And when I say 'actual invested capital,'" says Mr. Baker, "I mean invested capital as an income producing factor."

There may be wholesalers who have some investment in mines or stock of mining companies, and that will take a different classification under another section of the law. There is still another class of wholesalers who have a considerable investment, but disproportionate to their incomes. This class of cases is in the same position as the operating companies with a small capital and a comparatively large income, and will take a still different classification.

What Shall Be Done to Trouble-Makers?

AT EVERY period of the world's history society has tried to suppress its trouble-makers, for at all times it has been possible for a man diligent in promoting discord to set his neighbors by the ears. With false stories and innuendoes, with lavish promises and baseless visions of advantage, it is easy to separate fast friends and make coöperation between them impossible. Strange to say, the professional peace-makers are among the most prolific spreaders of doubt and suspicion.

Early in the history of common law, the crime of barratry was defined as an attempt to stir up trouble either in the courts or elsewhere. It was ultimately decided that three such meddlings in other people's business justified the courts in meting out punishment. Then came the period when the trouble-makers became so persistent and annoying that communities established and courts condoned such instruments of torture as the scold's bridle and the ducking stool.

Today we are face to face with somewhat different but more troublesome bodies of disturbers—the Bolsheviks or Industrial Workers of the World. The emissaries of this organization make all kinds of impossible claims for a new order they intend to establish. Sneaking around from camp to camp they leave their literature advocating, it is said, a working day of about two hours and all kinds of phenomenal pay, and claim that the other six hours and the difference between the pay they advocate and the pay now received represents capitalistic peculation.

With the outcome of the work of these disturbers we may soon have to cope. Without any militia and with no state police in many of our commonwealths it will be an impossible matter to keep order. It is a question whether freedom of speech and of the press requires us to give place to such disturbers in peace or in war. To all matters there is a limit.

The peddling of information is subject to the same laws as the peddling of medicine. No man may sell talcum powder as aspirin or water as antitoxin. To do so is a fraud. Similarly, a man is not allowed to advertise a company's stock in a fraudulent manner. Even particularly unscrupulous religious healers have been arrested and punished because they imposed on certain of the feeble-minded and credulous.

If we can interfere with such freedom—freedom of trade and of religion—we surely should have ample justification for suppressing at least the most dangerous forms of freedom of speech. Some attempt should be made to have all men tell the truth. If the jail is not to be used, at least the bridle and the ducking stool and the rail might serve to make such perversions of truth appear as ridiculous and odious as they really are; and make the dissemination of such untruths an employment not unaccompanied by discomfort. These men cannot be martyred, for they know their faith is vain and that their "facts" are made to suit the gullibility of their hearers.

Do Not Die Too Soon to Get Tuberculosis

SUBJECT to revision, the United States Bureau of Mines says that 3.39 persons were killed per 1000 employed in 1918. If, therefore, 1000 men, subject only to accidental death, went to work at 16 years of age, 295 years thereafter all of them would, at length, have succumbed to the dangers of the mine by the laws of probability. The last man to die would be 311 years old when he was gathered to his fathers.

The number of men dying of accident year by year, assuming that the risk of death is independent of age, would decrease in proportion to the time, because the number exposed to the risk would be reduced by death year by year. Thus the average age of death would be the age of entrance into the mine, sixteen, plus a half of 295 years, or about 163 years—nearly three generations.

No wonder the mine worker expects to entertain the grim reaper in the village rather than at the mine. Miss Alice Hamilton, of the Bureau of Labor, speaking recently before the Academy of Political Science, said confidently of the mine workers: "Of course, we know that a great many of them do not live long enough anyway to get consumption; they die of accident." This, of course, is unfair, for the accident rate is not so high as suggested; and hence the accident rate does not in any way explain the low tuberculosis rate. She added, however, most creditably, "But even those who survive do not seem to get consumption when one would expect them to."

Miss Hamilton suggests that the miner may be subject to pneumonia, and the probability is worth inquiry. Especially does it seem likely in view of the large number of mine workers who have recently succumbed to "influenza." The actual cause of death was doubtless influenza's twin sister, pneumonia.

The Department of Commerce says, "Buy even at a sacrifice, for such purchases are patriotic." The Railroad Administration is making no effort to buy coal—and hence is surely to be numbered among the unpatriotic slackers.

Making a Mock of Thermo-Dynamics

WHAT is the efficiency of a miner? He consumes at least 3000 calories in food a day, which is the equivalent of 5400 British thermal units, or 4,201,200 foot-pounds of energy. In an eight-hour day, working steadily and at limit of capacity, he probably does 800,000 foot-pounds of work. He rarely does anything near as much as that, but when he does his best he is about 19 per cent. efficient. It is more than likely that his average efficiency does not rise above 10 per cent., and often it is far less. Shall we argue therefore that the farmer should work less hours for the miner, seeing that the mine worker's efficiency in making use of the food values supplied him is only about one-tenth and

never exceeds one-fifth of the ideal performance?

Yet that is just the line of argument adopted by Mr. Smillie, the miners' leader in Great Britain, when he addressed the Sankey Commission on the wage demands of the mine workers. He said that the public did not utilize from the coal mined more than 10 per cent. to 15 per cent. of its heat content, so why should the miner be sweated to supply coal to the public when it used his product with such real or apparent wastefulness? It is certain that it is impossible for the public to convert more than about 25 per cent. of the heat in coal into work. It should do more than it is doing to reach that figure; but the miner also, who can produce 19 per cent., should not be content with only ten.

It is extremely easy to say that we should work without waste, that there should be an exact balance between work performed and heat expended; but this is absolutely impossible. We all need to be more efficient, but it must be remembered that if we render an account for 25 per cent. of the heat units delivered, regardless of whether we are stationary engineers or manual laborers, we shall do most excellently. Waste and work are unfortunatetly twin brothers.

If, however, there is to be economic use of material, surely the profit of economy should go to those who institute it, or to the consumer, and not to the raw-material man. Economy is attained not without labor and expense; and if another party is to reap what the first party has sown, there will be no economy, for it will not be a profit but a loss to the man who puts the economy in operation.

Government ownership is coming like a steamroller, crushing down all opposition. We do not dare to deny it, but would delay it as long as possible. Where workmen are all combined, and perpetually striking for more pay, shorter hours and more privileges, government control must come. Then the industrial army will be formed and everyone will be conscripted and subject to court-martial. The striker will be a traitor liable to summary punishment. The men who will not work will languish in jail. There is no cure for this desperate outcome—other than sanity in the public. There is, of course, another solution. Government need not be tyrannical under government ownership—for we can always starve.

Increasing Reliability of Mechanical Equipment

A RATHER significant indication of the increased confidence the coal producer has in the machinery end of his operation is shown in some figures taken from the mine inspectors' reports of Pennsylvania. It was customary, even as late as 1910, to allow a large factor of safety with any mechanical equipment, and especially with mine pumps, since any failure of these would occasion serious results.

In more recent years, however, the higher grade machinery, as well as the coalman's increased knowledge and confidence in it, has tended to reduce this safety factor decidedly. The mine inspectors' reports, for instance, show that during the period 1910 to 1915 the capacity of the mine pumps in the bituminous field of Pennsylvania only increased from 510,000 gal. per minute to 727,000 gal. per minute, or 18 per cent., while the actual water handled during this period increased from 300,000 gal. per minute to 418,000 gal. per minute, or 40 per cent.

This increased confidence in the reliability of their mechanical equipment has been accompanied by a substantial increase in the capacity of the individual units. In 1910 the average number of gallons per minute handled by each pump was 184, and the same figure for 1916 was 256.

The increased use of machinery and mechanical equipment in the mining industry is showing a growth that the well-informed operator is watching carefully. In fact, with labor costs continuing at existing high levels, the operator who fails to adopt all possible means of replacing man-power with machinery may find himself driven out of business.

Since and including 1913 Great Britain has bought 27 billion dollars worth of goods and sold 16 billion, incurring obligations of 11 billion dollars. The pound sterling, the value of which never changed, was $4.87. It now is $4.57. No wonder Great Britain is not keen to plunge any further into debt.

Dig Deep!

THE vital necessity for American industry at this moment is the success of the Victory Liberty Loan. Success of this loan is required for the maintenance of our national prestige. That goes without saying. The United States pays its debts, pays them quickly, fully, generously, and particularly does not allow the expenses of a war to drag on in endless claims long after the war is over. Four loans are already out. In order to enhance their value, the present loan must be heavily oversubscribed.

So much for the national side of this loan. The industrial aspect strikes home just as forcefully. We are no longer standing at Armageddon; the tide of battle has flowed with tremendous force in our direction. Now we are on another tide, which also must be taken at the full, or this country will lose all it has to gain of the benefits of peace. The industrial tide is setting in.

Before industry can function without friction several things have to be accomplished. First, the finances of the country must be in a settled state. This cannot be until the loan is a success. While money is withheld from its proper use by the Government it cannot be freely loaned to individuals; the risk of taxation, of new flotations, is too great. Second, the men who were in the army must be quickly taken into the fabric of industry. A floating population of discharged soldiers, or even the keeping of a million and more soldiers under arms, will destroy the even balance of industry, affecting capital, as much as it affects labor, with a sense of insecurity. Finally, the war industries of the country must be turned to other purposes.

For these things, as well as for the care and education of wounded and crippled men, the Victory Liberty Loan is the essential. It comes at a time when the prospects of expansion for American industry are brighter than ever. With Europe begging for the products of our fields and factories, it would be folly for us to hold back. It is possible for America to take the commanding position in the world of finance and industry. But no country can command which cannot settle its own affairs. To settle our affairs we have, first and above all, the Victory Liberty Loan. We must dig deep into our money pockets, or we shall never dig at all in the industrial mines of the world.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

How can we carry over to the mine worker, who is bone of our bone and flesh of our flesh, that he is the person of all others who wants more than anybody else? The rest of the world is satisfied with the eight-hour day, the mine worker wants six hours. Others are content with a 5½-day or a six-day week, the mine worker wants his week to be of five days and yet he asks for more and more pay.

When he realizes that everyone else has to pay him how can he make these demands, except on the ground that he has a harder time than other people or more risk than the generality or loses more time on his way to work or has some other unspecified or unspecifiable disability? The first statement—that his work is unusually hard—does not seem to be true or why is there an equal scale inside the mine and on the surface. As to the second count, it is true there is some risk in mining. It is partly compensated by legal provision, but after all it is not so great as some people think. It deters almost no one from entering the mines, and its importance is mainly apparent because it has been emphasized statistically whereas other industries competing for the same labor have had no statistics on which the public could base an indictment.

Has Miner Right to Shorter Day Than Others?

As for the time needed to reach the working face that is usually met in big mines by the man trip, and it is fair that it should be so wherever the underground distance to the working face is over a mile. The day man is quite generally getting pay for all the time he is at the plant. He gets a full eight hours for eight hours corporeal presence regardless of whether he is working or walking or merely gathering up his tools. The miner does not work eight hours for the most part, and if he does it is because he elects so to do. He can easily let the eight hours cover the trip in and out of the mine.

So there is little reason for the mine worker's insistence on short time, especially in this country, except as the mine worker makes it a temporary practice to fill a temporary need. The general Industrial Conference in Great Britain has just established the eight-hour day. Yet at the same time the Sankey committee has promised to the privileged mine worker the seven-hour day to date from July 16 and the six-hour day from July 13, 1921. But that does not satisfy the mine worker. He wants wage increases also and big ones, and in America he wants the six-hour day now and forever hereafter and wage increases also.

Short Time as Unfair as Short Weight

On Mar. 31 we read that the South Wales miners reject the promised *six*-hour day (to which indeed there is a small qualification) an increase in wages of 50c. a day, and a voice in the management. On Apr. 7 we read that the Industrial Conference provides throughout England an *eight*-hour day, a national minimum wage, complete and unrestricted recognition of the trade unions, responsibility of the State for the unemployed and a National Industrial Council.

This is hailed as a Magna Charta Libertatum by the British public. The mine workers will have nothing to do with such a document. They would have the industrial workers of Great Britain work for them eight hours while they work for them in return only six hours a day. It is not a square deal. Can it be that the miners of Great Britain, after whom our miners are trying to pattern, are not square and don't pretend to be? This cannot be believed. The probabilities are that they do not understand the implications of their actions. They do not realize that there is no one so mean and miserable in the slums of the British cities, no farmer's laborer however humble, that they are not robbing by the fact that they give them short time in return for a day of eight hours.

A short day, like a short weight, is an abomination that rich and poor should hold in abhorrence. The short-time worker, rich or poor, robs the public of service. A man is only faithful to his trust when he plods along as unwearyingly as his fellow worker. He cannot take up his tools and quit at 2 p. m., when his neighbor works for him till 4 p. m. The miner should play the man, and when time is reduced it should be reduced everywhere and not in one occupation alone.

Apparently some of the anthracite miners of this country do not like the provision of the union that they may not work on idle days. They say they will strike if they are not allowed to prepare coal when the breaker is idle. It is to be hoped that the public will soon make this dispute between miners and other mine workers purely academic by providing work for 6 days in the week.

Contrary Currents in Hard-Coal Region

On Apr. 1 Christ J. Golden was formally inaugurated as president of District No. 9, United Mine Workers of America, a district which covers the Schuylkill field of the anthracite region of Pennsylvania. In connection with the inaugural ceremony came one of the greatest labor demonstrations ever held in the lower end of the coal fields. In his inaugural address, President Golden supported the recent demands enumerated by National President Hayes, in which he demands a six-hour day for the miners and a substantial wage increase.

The mine workers of Pine Ridge and Laurel Run Collieries of the Hudson Coal Co., in Luzerne County, recently called a strike when the grievance committee of the company and the officials of the concern failed to reach a settlement over a minor grievance. As a result the collieries are not working.

The strikers do not have the sanction of the organization because they acted before notifying the district officers. From what can be learned, it appears that the cause of the trouble is alleged partiality shown a member of the grievance committee, because of his activity in organization affairs. It is fully believed that the difficulty can be readily handled.

In the Lehigh region, the miners have served notice that they will tie up the Beaver Brook colliery indefinitely unless they are permitted to cut coal on idle days. The men claim that they are rushed in production on the days that the breaker works if they are not given a chance to get a supply on hand.

All the strippings in the Hazleton region operated by the Central Pennsylvania Quarrying, Stripping and Construction Co. started on a nine-hour basis on Apr. 1, following the winter's suspension. Heretofore the men worked ten hours, but the union asked for the reduced shift and this was agreed to without any trouble. The new schedule will remain in effect until next March, when the present contract will expire, the date being concurrent with the expiring of the anthracite mine wage schedule. Approximately 5000 employees are affected.

The Bolsheviki are still trying to get a firm hold in the Wyoming Valley, a place they have thought for a long time suitable for their operations. Many threats have been made against mine foremen and mine owners. On Mar. 31 James Dixon, mine foreman of the Delaware, Lackawanna & Western R.R. Co. Coal Department, was attacked by two men, being stabbed in the arm and in the breast. Three shots were fired at him, but without effect.

Don't Start Anything You Can't Finish

If the mine worker insists upon shorter hours, others will want them too. If as large a wage is paid the mine worker for the short day as for the long day, others will want to be paid in the same measure. As a result, the mine worker will have to pay more for all he gets. There's no such thing as doing less and having more. It's production, not wages, that really counts. Suppose Mrs. Mine Worker decides to work six hours a day with two days off, instead of 16 hours and no days off, where will Mr. Mine Worker be?

Beware of starting a fight you can't finish. Other working men and women have two hands as well as you.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Contents of Conical Water Tank

Letter No. 1—In looking over some back numbers of *Coal Age*, which are always interesting to me, my eye rested on an inquiry (Vol. 11, p. 113), asking for the method of calculating the depth of water in a conical tank, of given dimensions, when the tank is half-full. It was stated that the height of the tank in question was 18 ft., while its diameter at the top was 10 ft. and that at the boteom, 14 ft.

By a trial method, it was found that the depth of water in this tank when half-full would be 7.54 cu.ft., which is correct. However, I set to work and succeeded in developing a general formula, that gave a direct solution of such a problem. Believing that this is of interest to *Coal Age* readers, I submit the formula for consideration. It is as follows:

Let D = the larger diameter and d the lesser diameter of the tank and indicate its height by h. Then, if x = the depth of water in the tank when half-full,

$$x = h\left(\frac{D - \sqrt[3]{\tfrac{1}{2}(D^3 + d^3)}}{D - d}\right)$$

Substituting the given values in this formula, we find for the depth of water in the tank when half-full,

$$x = 18\left(\frac{14 - \sqrt[3]{\tfrac{1}{2}(14^3 + 10^3)}}{14 - 10}\right) = 7.54\ ft.$$

The use of this formula avoids solving such a problem by trial, as was suggested. CHARLES E. WALLER.

Allentown, Penn.

Drawing Pillars in Machine Mining

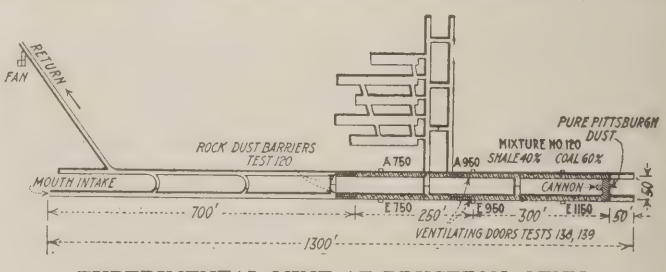
Letter No. 12—Allow me to add a word in the discussion having reference to drawing pillars with machines in rooms that have been opened to a width of 27 ft. and driven up 250 ft., under 200 ft. of cover and a strong sandstone roof, as suggested in the inquiry of "Operator," *Coal Age*, Jan. 2, p. 32.

In the first place, in driving rooms with the Sullivan shortwall machine to a supposed width of 27 ft., it will generally be found that the actual width is 30 ft. and the remaining pillars are far too thin for the proper support of the roof, to say nothing of drawing them back with machines. It has been assumed by one writer that these rooms are probably driven on 40-ft. centers, which would allow for pillars 13 ft. wide; but, even supposing that the pillars were 20 ft. wide, it would hardly be practicable to follow his plan when mining with machines, under the conditions mentioned.

Let me say then, assuming the rooms have been driven 27 ft. wide, under the conditions named, I would not use machines to draw back the pillars; but they should be removed by pickwork and not with machines. Coal cutters are too costly to risk in this work. The best miners should be employed and the work double-shifted, so as to draw the pillars rapidly.

Too much cannot be said in emphasizing the fact that it is a wilful waste of coal resources to open out work under the conditions described and in the manner mentioned. It would generally be found impracticable to recover more than but a small percentage of the coal remaining in the pillars.

Instead, the work should be planned to drive the rooms as narrow as possible and avoid paying yardage. This will require the use of comparatively little timber in the first workings, and the posts will not be crushed and broken but can mostly be used again. The rooms must be driven on such centers as will give a good width of pillar to be drawn back when the rooms have reached their limit. Such a plan will give opportunity to use machines on the pillars and a larger percentage of coal will be recovered.



Looking over the district here, one can find hundreds of rooms standing full of timber left to decay, and many thin pillars that have had to be abandoned, because they could not be drawn with safety. I have gone into these rooms and drawn great quantities of timber that had been left; but the pillar coal cannot be taken out as the work is too dangerous, and the coal would not pay for moving the rubbish, which would have to be done before work could be started on the coal.

Linton, Ind. W. H. LUXTON.

Current Velocity re Mine Explosion

Letter No. 1—In the article of G. S. Rice and W. L. Egy, which appeared in *Coal Age*, Feb. 13, p. 308, entitled "Effect of the Velocity of Ventilating Current upon Mine Explosions," the writers refer to three tests, Nos. 138, 139 and 120, at the Bruceton experimental mine, to support their conclusions that air movements and ventilating conditions have no appreciable effect in starting and extending explosive combustion in mines.

The arrangement of the experimental mine at Bruceton is shown in the accompanying diagram. In all

EXPERIMENTAL MINE AT BRUCETON, PENN.

the tests regarding explosions, a cannon that was placed in an offset in the inby crosscut, 1250 ft. from the mine entrance, was employed as a means to initiate the explosion. The cannon was charged with 4 lb. of black powder and fired electrically from the outside of the mine.

The main features of the three tests mentioned were the following: Two heavy doors were located, one in the intake entry and the other in the return air-course, at points 300 ft. outby from the crosscut where the can-

non was fired. The door in the intake entry was hung to open inby, while that in the return air-course opened outby. When the tests were made, both of these doors were closed, so as to form a dust-charged explosion zone within the doors.

The dust charge, consisting of a 50 per cent. mixture of coal and shale, was distributed throughout this zone, at the rate of 4 lb. per ft. of entry. It is stated that, under these conditions, no difficulty was experienced in obtaining an explosion and the resulting flame or explosive velocities were high and the pressure strong, as indicated by the recording instruments that were installed for the purpose at several points on the intake and return entries.

Effect of the Inrush of Air Following the Firing of the Cannon

The conclusions of the writers are based on their assumption that there was no air current moving, in the immediate vicinity of the cannon, at the time the shot was fired. Let us see. Only a short time ago, it was stated by a mining engineer, in a previous discussion on the influence of the air factor in producing explosion in a mine, that "all will concede that an inrush of air follows the firing of a shot."

This statement has a particular significance in the present instance. Following the firing of the cannon in the Bruceton mine, the air was compressed in the space between the cannon and the intake door, which could only open inby; but the door on the return entry, opening outby, gave vent to an outrush of air. As a result, there was an area of depression at the cannon, followed immediately by the rush of the compressed air from the intake side toward the cannon, and causing the intake door to open inby and admit an inflow of fresh air into the explosion zone.

There can be no question but that this rush of air carried with it a probably greater amount of dust than the first outrush through the air-course. The effect of this difference is plainly shown by the presence of the greater pressure in the intake entry, which was due to a higher rate of explosive combustion. The records show that, in test 139, the pressure in the entry was nearly 50 per cent. greater than that in the return air-course, Notwithstanding this pronounced discrepancy, the writers of the article dismissed the matter with the remark that "the development of the explosion was roughly symmetrical in both branches."

Important Test Carefully Analized

Test 120 was made in the presence of members of the Mine Inspectors' Institute of America who were present in large numbers. The arrangement and result of this test are explained in great detail by the writers, who deemed it of special importance and who state that the ignition zone was prepared with pure Pittsburgh coal dust, consisting of 60 per cent. coal and 40 per cent. shale, distributed at the rate of 3½ lb. per ft. of entry. Barriers of various kinds limited the explosion zone at different points.

It is stated that "the explosion was a relatively weak one, with low velocities. . . . The development of the explosion in the two entries was quite similar, the velocities in the return air-course being a little greater than those in the intake entry. . . . The pressures developed were light, being 5 lb. at E 1150 and E 750, and 2 lb. at A 1150 and A 750." This description is followed by the statement, "Thus, there was practically no difference in the development of the explosion in the intake and return."

From the data given here, the writers have concluded that the rate of velocity of an air current moving toward the place of origin has no appreciable effect in the development of a dust explosion. To show that such a conclusion does not appear to be warranted by the facts of other tests, let me call attention to tests Nos. 9, 10 and 11, made at the Bruceton experimental mine, for the purpose of ascertaining the extent of pressure produced by the firing of the cannon alone, in the entire absence of coal dust and with the entries sprinkled throughout their entire length.

In test 9 all the circuit breakers, seven in number, were adjusted to operate at a 2-lb. pressure. When the shot was fired, only three of these circuit breakers, located within a distance of 300 ft. from the cannon, operated and the remaining four failed to work. In test 10, only two circuit breakers were used. These were placed about 100 ft. outby from the cannon and set to operate at pressures 3 and 4 lb., respectively. Both of these operated. In test 11, two circuit breakers were installed, in the same manner as in the previous test; but arranged, the one to operate at 5 lb., and the other at 6 lb. pressure. Neither of these operated.

What the Low and High Pressures Really Show

In my opinion, the low pressure of 2 lb., in the air-course, which resulted in test 120, was caused by the shot alone; and, notwithstanding the presence of flame observed in the air-course, the absence of additional pressure proves, also, the absence of explosive combustion. In the entry, however, the situation was different. It is evident that the pressure due to the shot should not be appreciably greater in the entry than in the air-course, the resistance of which caused the pressure. But, at Sta. E 1150, a 5-lb. pressure was registered, which fact clearly proves the occurrence of explosive combustion in that vicinity.

Let me urge, here, that if the velocity of the air movement toward and away from the cannon, at the time the shot was fired, is not a factor in the development of explosive combustion *in the entry*, and if its absence is not responsible for no such explosive condition *in the air-course*, how are we to account for the difference in these results? I submit that the claim of the writers that "there was practically no difference in the development of the explosion in the intake and the return," is not supported by the recorded facts, since there is apparently no evidence whatever of the development of explosive combustion in the air-course.

It is unfortunate that no attempt was made to check the conclusions of the writers, by repeating test 120, under the same conditions, except with the fan reversed, so as to make the air-course the intake and the entry the return. Allow me to suggest that such a test can still be made. I feel safe in the prediction that the resulting difference in pressure between the air-course and the entry will probably be more pronounced than in the test already made, and that the greater pressure will then be found in the intake air-course, which would unquestionably show the development of explosive combustion at that point. Should this be the case, the effect of air movement and ventilating conditions will be clearly and definitely proven to be important factors in the development of explosive combustion in mines.

John Verner,
Chariton, Iowa. Former State Mine Inspector.

Efficiency of Mine Officials

Letter No. 5.—If I have a hobby, it is efficiency, and I was glad to read the letter of William Gorman, *Coal Age*, Jan. 16, p. 159, inviting a discussion of the efficiency of mine superintendents.

When a man is called "efficient," I understand it to mean that he is possessed of the art of doing things in the right way, at the right time and with the least expenditure of time and energy. I think that most men will agree with me in this opinion.

Now, there are several things to be considered before one can say that a man is efficient, or that he fails in this respect. As Mr. Gorman suggests, many a good man has been hampered by conditions that are beyond his control. He may be handicapped by internal friction existing in his organization; and the results that he is able to accomplish must be judged in the light of these hindrances, and not by comparison with the work of another whose problem is simpler.

To obtain good results in efficiency, there must be the coördination of effort in the work of individual employees. A mine superintendent must have the coöperation of the underofficials, from the mine foreman all down the line and including the most humble worker. Not only this, but he must have the coöperation of the office and the higher officials whose duty it is to supply him with what is needed to enable him to accomplish the best results.

In other words, there must be the coördination of the work of every department. While it may be said that this is the efficiency of the organization rather than of the man, it will be admitted, readily, that no man can be efficient in his work without such coördination and coöperation on the part of everyone employed.

Efficiency Depends on Ability to Perform and Knowledge of the Game

In addition to the two factors mentioned, efficiency requires that a man be possessed of a certain degree of ability to perform, and the knowledge required to direct his efforts intelligently. I wonder if Mr. Gorman's barber didn't know more about coal mining than he knew of the tonsorial art. I have known men quick to learn a new trade; but does that show efficiency? Efficiency is revealed in the performance. The men who employed this erstwhile barber must have observed the characteristics he possessed and that fitted him for other duties. It was the recognition of such characteristics that induced them to put him in charge of their mine.

Ability to perform and a knowledge of the game, from the sump to the tipple, should be and are the requisites of an efficient superintendent. Who would select a man to boss a job who doesn't know, or who isn't sure, how that job should be done? In the operation of any property of any size, there are always a number of men employed who are not only well versed in the game but who possess, besides, the tact and diplomacy that fit them for a superintendent's job.

This fact should recommend that promotion, in an organization, should be within the grasp of these men. Such a policy will do more to hold an organization together and coördinate the work, than any other plan that can be adopted. I have been in the game a number of years and have seen all manner of men employed as bosses who were promoted from the ranks. Rarely have I seen jealousy shown when a man on the job was promoted through merit. Instead, it is generally recognized that he possessed the necessary qualities and deserved advancement.

In closing, let me say that, in every instance where efficiency is evident, each worker from the superintendent down is personally efficient. Organization makes the men a unit and all work for the common good.

Golden, Colo. Fred L. Serviss, Sr.

Letter No. 6—It has been a pleasure to read and study over the many interesting letters that have been written in *Coal Age*, and particularly those bearing on the efficiency of mine foremen and superintendents. The letter of William Gorman, in the issue, Jan. 16, p. 159, has taken me back over past experiences and recalls many interesting thoughts and incidents of my own observation.

The remarks that follow will bear more on the inefficiency of superintendents, hoping by that means to show by contrast what is required of a truly efficient man holding that office. My memory carries me back to the time when, as a plain miner, I observed instances where the company would spend money right and left for work that could accomplish no good end, save the employment of men needing to work. The undertaking would probably be done on the recommendation of a superintendent who had no practical knowledge of underground requirements.

Superintendents Without Practical Experience

It has been my lot to come in contact with some of these men. They remind me more of a young boy who runs wild and must have his fun, without a thought of where his next suit of clothes or next pair of shoes will come from. In other words, a superintendent of this class directs work, without stopping to *think;* or, if he thinks at all, it is not in the right direction. The reasoning of a plain, practical mining man falls on deaf ears. Such a one, as we say, will not listen to common horse sense regarding a proposed plan of mining, system of haulage, drainage or ventilation. He prefers to follow a plan of his own that may look well on paper but will seldom work in the mine.

My experience has taught me that the efficient mine official must get his men together, talk over a proposition and get their ideas, which will enable him to view the matter from every angle. The idea is to have a plain, old-fashioned, straight talk with all parties concerned, and adopt such a plan as will meet every requirement. When this is not done changes will have to be made later that are expensive, if indeed the entire plan does not have to be abandoned.

I can well remember working in a mine, some time ago, where the workings had been extended to a point that required the laying of a 4- or 5-in. pipe line, in order to drain a certain section of the workings. The superintendent was a man that had few practical ideas, and whose visits to the mine were few and far between. He was chiefly interested in keeping down expenses and making a good showing on the cost-sheet, each month.

While this superintendent may have had a vague idea that the laying of the pipe line mentioned would enable his company to take out a large tonnage for a considerable time to come, the one thought uppermost in his mind was what the expense would mean on the showing of his cost-sheet for that month. As a result, he made

this necessity of purchasing a few hundred feet of 4- or 5-in. pipe the excuse for his recommendation to abandon the mine.

Without further investigation, on the part of the company, the order was given to pull the tracking from rooms and entries, and take out all equipment that could be moved. In other words, the mine was henceforth and forever abandoned. The tipple was removed and the surface plant transported a mile further, around the side of the mountain, to another opening that had been made in the top vein of coal. Here the superintendent set men to work to clean up the entry and put down a slope to the lower seam, which was the same that we had just abandoned in the old mine.

A Foreman After the Superintendent's Own Heart

About this time, a change in mine foremanship took place. The new foreman was a man very much after the superintendent's own heart. His main idea was to get out cheap coal. I need not add that six months later this mine was shut down, for the reason that it was not paying expenses.

Now, notwithstanding the fact that $65,000 to $75,000 had been spent in opening and equipping this mine, orders were again given to pull everything movable and set up the plant at another opening, about a mile further around the mountain, at a place where the output had been 900 tons of coal a day. There, the entry was cleaned up and three more slopes were sunk to the lower seam, which was the same seam of coal worked in the two previous openings.

It is not possible for me to attempt to describe the superintendent's thoughts. To me, a practical miner, the entire proceedings appeared as boy's play. A few years later, the same company went into the hands of a receiver, and every practical mining man will say that this was the result of employing inefficiency in the practical work of mining coal.

Let me say, in closing, what has already been remarked in one of the letters I have read, that the most disagreeable thing to a mine foreman who is practical, is to be compelled to work under the instructions of an inefficient and unpractical mine superintendent. I am sorry to say that it has been my bad fortune to experience this difficulty in more than one instance.

As long as things go well, and the coal keeps moving, the foreman is all right in the eyes of the superintendent. But, when conditions change, as they ever will in coal mines, the superintendent lays everything to the foreman and suddenly charges that he is "a most inefficient man." Too often, there is no investigation made by the company to ascertain the actual facts. The increased cost of production is the one thing that blinds the eyes of the company to everything else, and the mine foreman is the man who must stand the blame.

Pruden, Tenn. EXPERIENCE.

Efficiency in Firebossing

Letter No. 10—In the discussion of this subject, kindly permit to say that I do not agree either with those correspondents, who take the position that a fireboss should never, under any circumstances, be called upon to do anything else than his own particular work; nor yet with the idea advanced by Edward H. Coxe, *Coal Age*, Jan. 23, p. 199, that "a fireboss will often have time to busy himself looking after a pump, laying a piece of track or setting needed timbers.

From the trend of Mr. Coxe's letter, one is led to believe that he has never performed the work of firebossing himself and does not fully appreciate the dangers of the situation.

The mining laws of Tennessee provide that all mines, generating gas in sufficient quantity to be detected with the safety lamp, are to be classed by the chief mine inspector as "Class-A mines," and must be examined by a certified gasboss (fireboss). The law further provides that this inspection must be made within three hours immediately preceding the time for the men to enter the mine for work.

Imagine, for a moment, the arduous duties of a fireboss who must go into the mine at 4 a.m. and proceed, alone, to explore the dark recesses of the mine, entering many dangerous places and climbing falls, lighted only by the dim flame of his safety lamp.

Even one who has not performed this task can imagine that it is not a pleasing job, and yet it is suggested by this writer that, after the fireboss has thus braved the dangers of the early morning alone, in his examination of the mine, he must finish out his shift by laying track, timbering, or running a pump, in common with other workers in the mine.

Here, in Tennessee, it is the custom for the fireboss when he has completed his morning examination, to notify the mine foreman in regard to the condition of the mine and explain the nature and location of any dangers that he may have found. Also, he informs the miners working in places that he has found to be dangerous that they must not proceed to work until their places are made safe. At times, he will assist the foreman in arranging the work for the day, by giving him any information in his power regarding the condition of the section or sections of the mine he has examined.

Standard of Firebossing Must Not Be Lowered

Speaking of the efficiency of firebosses, the work in their charge is of such a nature that the man who undertakes it should be the most efficient man in the mine, next to the foreman. The task and its duties should be so arranged as to make this position attractive to men who are capable and efficient. But, if the policy advocated by the writer to whom I have referred is to be followed, the result will surely be to lower the standard of firebossing, which would be a menace to the safety of the mine.

A few years ago, the Board of Mine Examiners, in Tennessee, concluded not to issue a fireboss certificate, on the ground that the only mines requiring the employment of a fireboss were those of "Class A," generating gas. They held, therefore, that a man capable of performing the work of fireboss should hold a Class-A certificate. This action of the examining board has had the tendency to raise the standard of firebossing in this state, both in respect to qualification and compensation for the work.

I have known places where the fireboss was only required to make the round of the mine and enter his report in the book kept for that purpose and then his work was done. I have known other places where the fireboss, upon completing his morning examination and reporting the condition of the mine, would continue to assist the foreman for a few hours in the early morning and then be relieved from further duty for the day.

I consider that it is the proper work of a fireboss to assist the foreman, in any manner that lies in his power, and to give him all the information he can regarding

the condition of the mine and work that requires immediate attention. I do not think, however, that the fireboss should be required to re-enter the mine to perform the work of timbering or tracklaying, or to serve in other capacities except those I have mentioned.

Briceville, Tenn. U. S. WILSON.

Panel System of Mining

Letter No. 3—Kindly permit me to refer to the inquiry of R. J. Pickett, *Coal Age*, Feb. 27, p. 419, regarding a change that he proposes to make in his present panel system in his mine. Allow me to suggest that it would seem that Mr. Pickett has not taken into consideration the comparative costs when considering this plan. Without meaning to criticise his judgment, I may say that the expense of the proposed plan would be much greater, especially in regard to the yardage paid for driving entries and crosscuts.

In my opinion, the difficulties he mentions in regard to bad roof, ventilation and drainage must be overcome by some other means. At present, he is driving one pair of entries and turns 20 rooms off of each entry or 40 rooms in all. In his proposed plan, he would drive two 12-ft. entries and two 18-ft. places for air-courses, in getting the space for 40 rooms. In doing this, even if he paid no yardage for driving the 18-ft. place, he would have the same yardage to pay in driving the 12-ft. entries as before and, in addition, he would have to pay extra yardage, in driving two lengths of panel entries 268 ft. each, with their crosscuts, besides twice the number of crosscuts on the butt headings. This would make a considerable increase in yardage, which must be paid for at the rate of $1.12 per yard.

In addition to the increased expense for yardage, it will be necessary for him to junk all the right-hand switches that he is at present using in the rooms driven toward the main heading. His proposed plan calls for left-hand switches only, since rooms are driven only off the 12-ft. entries, in each pair of butt headings. An item that is worth considering, also, is the upkeep of the 18-ft. air-course, which I assume will cause much trouble and expense because of the poor roof.

SOME HELPFUL SUGGESTIONS

Allow me to make one or two suggestions which are as follows: First, reduce the width of the 12-ft. entries to 8 ft., which will increase the width of the entry pillar from 18 to 26 ft. This should prove a great help, under the poor roof conditions he mentions.

Again, while turning the rooms on the same 40-ft. centers, I would widen out to only 22 ft. This would leave 18-ft. pillars between the rooms, which would afford three 6-ft. cuts with the machine when drawing back the pillars. Here, also, increasing the width of the pillars and decreasing the width of opening, would give better roof conditions and the loss of coal would be less when drawing back the pillars.

In order to overcome the poor ventilation, a close examination should be made to discover air leaks in the stoppings and doors, which should be repaired wherever this is needed. All airways and crosscuts should be cleaned up and every obstruction to the flow of air removed, in order to give better ventilation in the workings. In regard to the development advancing slowly, let me suggest the double-shifting of the entries and the employment of the best entrymen obtainable.

Clinton, Ind. MINE FOREMAN.

Perils in Reconstruction

Letter No. 5—Speaking of the perils in the work of reconstruction following the war, *Coal Age* writers have recently reflected the worry that is present in the minds of many mining men, concerning the future of industrial America. They appear to recognize that, in the past, the labor of our great industries has been recruited from central and southern Europe. Foreigners have been brought here, not alone to promote our industrial expansion, but as a means to an end, the purpose being to keep down wages.

One of the effects of the war has been to decrease our great army of industrial workers, and the cry has been raised that labor is scarce. It has even been suggested, by a writer in *Coal Age*, there should be greater laxity in the immigration laws of this country, at least for the present. I cannot agree with this suggestion. America should not be made the dumping ground for the off-scouring of Europe.

Now, this is no reflection on the great mass of foreign labor that has come to our shores and which our immigration laws are designed to sift out and select only those who are capable of making good American citizens. While it is true that the foreign element in this country provides the most radical of our labor leaders, it is still true that the great mass of foreigners admitted to this country are loyal to its principles. The list of dead, on our honor rolls, is replete with the names of boys whose parents were born across the water. One of the perils in reconstruction work is, then, the assimilation of this class to make them Americans at heart.

PERIL IN THE LACK OF THRIFT AMONG ALL INDUSTRIAL WORKERS

Another peril that faces us is the lack of thrift in the labor classes, both foreign and home born. One has said that a laborer whose expenses, in support of his family, are $30 a week, will work six days in the week at five dollars a day, when he will only work four days in the week if his pay is raised to $7.50 a day. My belief is that there are men who will not work steadily at any wage; and the man whose pay is raised to $45 a week will find his expenses increase in the same ratio. My observation is that the wage earner is never so far ahead of the game that he can safely take a nap. We must study, then, to impress the idea of thrift on our workers.

The question of wage adjustment is another peril facing us. The prevailing opinion among mine workers with whom I have talked is that there can be no decrease in wages until the cost of living has been reduced, which is fair and just. Obervation inclines me to the belief that the great mass of workers want to be fair toward their employers; and employers are coming more and more to see that authority and position do not excuse acts of injustice.

No men or set of men can cry down organization of either capital or labor. If the one is needed, so is the other. The monthly men, working on salary, are an example of what results from a lack of organization. It is sad that we cannot place ourselves in the other fellow's shoes and consider all problems from his standpoint. How greatly this would assist us in solving these problems of reconstruction, which confront us, as captains or privates in the great industrial army of mine workers and mining men throughout the country.

————, Penn. PENNSYLVANIA.

INQUIRIES OF GENERAL INTEREST

EDITED BY JAMES T. BEARD

Estimating Percentage of Grade

Kindly permit me to ask how the percentage of grade is estimated, as I am in a tangle and have had many useless controversies on the matter. To illustrate my case, I have drawn a square having a diagonal line reaching from corner to corner. Suppose the two sides of the square are each 100 ft. in length. I calculate the length of the diagonal would be $\sqrt{100^2 + 100^2} = 141.4$ ft. Now, if this line represents a grade line, I am told that it would correspond to a grade of 100 per cent. I shall very much appreciate being put right on this question. STUDENT.

Morgantown, W. Va.

As was explained in *Coal Age,* in answer to a previous inquiry (Vol. 14, p. 756), there are two methods of estimating percentage of grade. One of these is based on the rise per hundred feet of *horizontal distance,* while the other is based on the rise per hundred feet of *pitch distance.*

In the case cited by this correspondent, the rise is 100 ft. in 100 ft. of horizontal distance. Therefore, estimating the grade on horizontal distance, the incline represented by the diagonal of the square illustrates a grade of 100 per cent. A 25 per cent. grade would be a rise of 25 ft. in going 100 ft. of horizontal distance. In this method of estimating, the grade is always the rise in 100 ft. of horizontal distance.

However, by the second method, when estimating the grade on pitch distance, the grade referred to in this case would be $100 \div 141.4 = 0.707$, or 70.7 per cent. Either method is correct, the first being used in fairly flat seams, while the second is more often used in steeper seams where the measurements are taken on the pitch. We can do no better than to refer this correspondent to the excellent letter of Richard Bowen, discussing this question in *Coal Age,* Jan. 9, p. 70.

Centrifugal-Pump Motor Heats

At the mine where I am employed, we are operating a centrifugal pump. The pump is located at the foot of a slope 200 ft. long and having a pitch of 40 deg. A 20-hp. motor is used for driving the pump, the speed of the motor being 1700 r.p.m. There is a 4-in. discharge and 5-in. suction, the suction pipe being 20 ft. long and the discharge the length of the slope or 200 ft.

The pump works all right when using the 5-in. suction, but gets overheated and starts to smoke when a 4-in. suction is used. Please explain the cause of this overheating of the motor, also explain the method of calculating the horsepower required to drive a centrifugal pump. PUMPER.

————, Penn.

Centrifugal pumps are designed to give the best results or develop the highest efficiency when the head under which the pump must operate is proportionate to the required discharge, the latter varying as the square root of the head. For a head of, say, 80 or 90 ft., the velocity of discharge may be estimated at about 12 ft. per sec., to enable the pump to develop the highest efficiency in its performance.

On this basis, it is easy to see that a pump designed to work under a given head must have a diameter of discharge portal in proportion to the head in order to enable it to handle any given quantity of water with equal efficiency. When such a pump is required to work under a greater head than that for which it was designed, there is an overload thrown on the motor, which causes it to heat.

In the case before us, the pump is discharging up a slope 200 ft. long and having a pitch of 40 deg. The static head on this pump is, therefore, $200 \times \sin 40° = 200 \times 0.6428 = 128+$ ft. Likewise, the suction head, for the same slope, is $20 \times 0.6428 = 12+$ ft., which makes the total static head on the pump, say, 140 ft.

To this static head must be added the friction head caused by the flow of water through a 4-in. discharge pipe, say 220 ft. long, to make some allowance for the friction in the suction lift. Assuming the proportions used in designing centrifugal pumps, the friction head h_f (ft.), for a length of pipe $l = 220$ ft.; a rise, $h = 140$ ft.; and a diameter, $d = 4$ in., may be calculated thus,

$$h_f = \frac{0.7l}{d\sqrt{h}} = \frac{0.7 \times 220}{4 \times \sqrt[4]{140}} = \text{say, } 11\ ft.$$

The total head under which the pump is operating, in this case, is then $140 + 11 = 151$ ft. Roughly estimated, a No. 4 centrifugal pump, or one having a 4-in. discharge portal, when operated by a 20-hp. motor at its full capacity, would develop its maximum efficiency under a head of about 95 ft.

Approximately, the horsepower required to operate a centrifugal pump under conditions that will develop the maximum efficiency of the pump may be calculated by the formula.

$$H = 0.00134d^2\sqrt{h^3}$$

In this formula, the h is the total head against which the pump must operate and includes the static head and the friction head; and d is the number of the pump or the diameter of the discharge portal. The formula also assumes that the diameter of the column pipe is equal to that of the discharge portal of the pump, both in inches, multiplied by four-ninths of the fourth root of the head expressed in feet, which conforms to the best pumping practice.

In answer to the question as to what is the cause of the overheating of the motor when a 4-in. suction is used instead of 5-in. suction, it can be said that the friction head is increased, by this change in the suction lift, about three times what it was in that lift, or, say nearly 5 ft. Judging from the data given, it appears that this pump is operating under a head greater than that for which it was designed and developing a very low efficiency.

EXAMINATION QUESTIONS

EDITED BY JAMES T. BEARD

Miscellaneous Questions

(Answered by Request)

Ques.—What are the dangers incidental to the operation of haulage on a steep slope and how would you guard against them?

Ans.—Haulage on a steep slope is subject to the following dangers: Cars may get loose at the top of the slope and run down the incline; the haulage rope or car couplings may break, allowing the trip or a portion of it to run back down the slope; men may be caught and injured or killed in attempting to travel up or down the slope; if the track is not well secured, danger may arise from its tendency to slip downhill, breaking a joint or otherwise dislocating the track and making a wreck possible. A wreck may also be caused if the empty trip is permitted to run down the slope with too great a speed.

To guard against these dangers, the top of the slope should be protected by suitable safety devices, such as safety blocks and automatic derailing switches to prevent cars running down the slope uncontrolled. A drag bar should be attached to the rear end of each trip hoisted. The haulage rope must be of sufficient strength for the load hauled, and inspected regularly at frequent intervals. All car couplings must be carefully made and have the required strength. These also should be inspected regularly and discarded when worn. The same is true also of the coupling pins and drawbars on the cars. The haulage rope should be recapped at least every six months or as often as may be necessary, as this is the weakest point in the rope and must be closely watched.

Men must never be permitted to ride on loaded trips or to travel the haulage slope when going in or out of the mine. The speed of haulage on a steep slope should be regulated not to exceed 8 miles per hour, or 6 miles per hour when hoisting or lowering men. The track in a slope must be well laid and secured from slipping downhill, and inspected regularly and cleared of all obstructions, such as coal or dirt that may fall from loaded trips. For the protection of the men working at the foot of a slope, there should be refuge holes cut in the rib and available for use in time of need. There should also be provided a good signal system and telephone or speaking-tube connection between the foot of the slope and the engine room.

Ques.—How would you protect a miner working at the face of a steep slope when hoisting operations are in progress?

Ans.—Refuge holes should be cut at frequent regular intervals in the rib, and a drag bar or "dog" attached to the rear of every loaded trip when it is being hoisted. As a further precaution men working at the face of a steep slope should cease work while the trip is being hoisted.

Ques.—What safety devices would you expect to find at a well-equipped shaft and on the hoisting machinery connected therewith?

Ans.—The top of the shaft should be protected by automatic safety gates arranged to rise and fall with the cage as it reaches and leaves the landing. The cage must be provided with a substantial hood or cover to protect men who are riding on the cage, from any loose material that may chance to fall into the shaft. The cage must also be provided with good safety catches operated by a strong spring. The winding drum of the engine must be provided with a powerful brake and there should be an indicator in the engine room, arranged to show the position of the cage in the shaft. In addition to such an indicator, the hoisting rope should be marked in a way to show the near approach of the cage to the upper landing to avoid danger of overwinding.

No engineer should depend entirely on the indicator to show him the correct position of the cage in the shaft, but must watch the marks on the hoisting rope as well. As an extra precaution against overwinding, many well-equipped mines have an automatic device that shuts off the steam when the cage has reached a certain position in the shaft; and, at the same time, the brake is applied to the drum to prevent the cage from being drawn into the headsheave.

Ques.—What tests would you make to assure yourself that these devices were in good condition?

Ans.—The safety devices requiring special tests other than a close inspection are the safety catches on the cage and the overwinding devices. In order to test the working of the safety catches, it has been suggested loading the cage and cutting the rope, or otherwise adopting an arrangement that will permit the cage to fall suddenly in the shaft, and observing the action of the catches to see if they arrest the fall of the cage. An overwinding device should, likewise, be subjected to the practical test to ascertain if it will properly perform the service intended.

Ques.—What is the horsepower of a pair of haulage engines, the diameter of the cylinders being 18 in., stroke, 32 in., number of strokes per minute, 30, pressure of steam, 40 lb.? The engine is geared as follows: The crank is connected to a shaft containing a pinion with 15 teeth, which drives a spur wheel having 75 teeth. On the same shaft containing this spur wheel is a pinion with 20 teeth, which drives a spur wheel on the drum shaft with 80 teeth.

Ans.—Since no mention is made of the cutoff in this engine, it may be assumed that the 40 lb. steam pressure is the mean effective pressure in the cylinder. The area of each cylinder is $0.7854 \times 18^2 = 254.47$ sq.in. The indicated horsepower developed in each cylinder is equal to the continued product of the mean-effective pressure in the cylinder (lb. per sq.in.), length of stroke (ft.), sectional area of the cylinder (sq.in.) and the number of strokes per minute. The horsepower is independent of the gearings, which need not be considered in this case.

$$I.hp. = 2\left(\frac{40 \times 2\frac{2}{3} \times 254.47 \times 30}{33{,}000}\right) = say\ 50\ hp.$$

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Coal Situation in England

The following account of the fuel situation in England is taken from a letter by C. W. Barron, which appeared in the Apr. 3 issue of the *Boston News Bureau*:

The economic foundation of England is coal. With coal she not only gives power to her ships, but economic balance to her trade. She exports coal to Argentina, or did before the war, and brings back the cheapest beef. Her ships carried coal for the round trip or could fill from English bunkers in ports around the world. You needed not to leave London to charter your ship and buy her coal supplies around the globe.

But England paid her coal producers an average pre-war wage of 6s. 6d. per day, or about $1.50. Measured by the day s work in the shift she paid 8s. 10d., or a little over $2 per day per working coal hand above and under ground. And per man there was never a ton of coal produced, only a fraction of a ton per man.

Higher Wages and Less Output

The war very nearly doubled the wages. The average in November, 1918, was 12s. 5d., or about $3 per employee, and 16s. 12d., or about $4 per man per shift. But the output per man diminished, due in part to poorer quality of employee as men were drawn off for the war, in part to the lengthening distances from the mining shafts, and in part no doubt to the labor union heresy of restricted output.

In South Wales the output per employee which had gone down from 269 tons to 243 tons from 1906 to 1913 fell to 224 tons in 1918. In this district labor cost per ton had more than doubled. Supplies had increased in cost per ton from 2s. 10d. to 8s. 10d. But it was the restricted output that troubled the country more than the cost, and Lloyd George in the fall of 1918 had to go personally to the coal-mining districts and stimulate the output with his inspiring addresses. He told the miners that they were the real fighters against the Huns and that more and more they must "heave coal at them."

When the armistice came there was another effort to increase the coal output, and 200,000 coal miners were given preference in demobilization. Other soldiers protested by riots. Coal was more sharply rationed than ever before in England, and the miners have now demanded a 30 per cent. increase in wages and a reduction from eight hours to six hours per day.

No Exports

A coal commission is now daily taking testimony, receiving volumes of statistics, sifting out the facts, and promises a report before April 1. If the demand is complied with it will add 9 shillings per ton to the price of coal, and this in turn will add 10 per cent. to the cost of steel making.

At today's prices, neither coal nor steel can be shipped abroad in competition with the United States, except by Government subvention or assistance in transportation.

There are one million men and two hundred thousand boys (under sixteen) and women who draw their wages from coal-mining, and of two hundred and seventy million tons produced in normal times, one hundred million tons go into ships in the proportion of about 25 million tons for bunker coal and 75 million tons for export.

England faces the situation calmly and fully understands that English coal which cost in 1913 eleven shillings per ton at the pit's mouth now costs 18s. and will cost not less than 26 shillings if the demands of the miners are granted and Lloyd George tells Parliament that Pocahontas coal in Virginia, the best that America now can produce, is now costing but 11s. per ton at the pit's mouth.

The American Competition

How to compete in the future with the United States paying twice the wages, yet producing coal at about one-half the English cost, presents many problems. Bunker coal f.o.b. in English ports is costing today 36 to 37 shillings per ton, or about $9. It is of course a controlled commodity, the Government naming the price, raking off a profit, and paying not less than 6d. per ton as expense of control.

Nevertheless the price of bunker coal f.o.b. at American ports is $5, or less than 20 shillings per ton. If the Government keeps the control, and adds 9s., or $2 per ton, the cost of English coal f.o.b. becomes more than double the ship's cost per ton in the United States.

Can England put in coal machinery? The answer is that English coal veins run down to 23 in. in width while American coal seams run up to 40 ft. in width, and in the United States 16,000 machines cut 253 million tons of coal, while in Great Britain 4000 machines cut only 27 million tons. In many mines a large part of the miner's day's work is consumed in walking between the shaft and the distant coal face at which he must work.

"Nationalize the mines," cry out the coal miners. Nationalization of coal mines has been a cry in English politics for a generation. It has taken on a new phase of late—a Bolshevik demand in some quarters—that as the Government wants output, and this is more important than profit, let the Government buy the mines and give them to the coal miners, who will run them for output for the public and profit for themselves. The miners say: "We know our own slackers and if we had all the profit we would quickly throw out all the slackers." Thus does Bolshevism in practice propose to undo the philanthropy of its theories. The main response in England is: "A man in this country shall get what he pays for; stealing is not yet recognized."

Combination to Meet Competition

There is one sensible suggestion, and that is to nationalize the mines by buying out the 1452 coal owners of whom 434 produce less than 2000 tons a year, and by consolidation of interests and concentrated energies reduce the expense and enlarge the output. It is thus proposed under the form of a national trust to remove the waste of disjointed ownership.

It would be a singular outcome if England should turn to a trust combination to meet American competition where the economies of combination in trust are forbidden under the Sherman law and the legal decisions superimposed thereupon.

Combination of mines may afford some relief, but confiscation of all the royalties and mining operators' profits would not give one-half the increased wages demanded by coal men. Royalties are about 6d. per ton and the pre-war profits per ton were only 1s. The coal operators' profits have been expanded during the war to 3s. 6½d. But of the 60 cents per ton increase the Government in excess profits and income taxes takes the major part.

As near as can be estimated the total capital in the English coal industry, not including freehold realty, is 128 million pounds sterling.

The Controlling Factor

The British official record shows that in 1916 the worker in the United States produced 896 tons of soft coal per annum, and in anthracite mines 548 tons of coal per annum. This compares with 207 tons of anthracite per man per annum in the mines of South Wales and only 222 tons of soft coal per man per annum in South Wales.

The comparison shows more than four tons of soft coal for the American worker as compared with one ton of soft coal for the English worker. Many mines in the United States have a much higher production per man, but the average English production in soft coal ranges from 230 to 260 tons per man per annum.

The coal hearing occupies a page or two in the daily press. But neither from the hearing nor the press will you learn the supreme and controlling fact and factor, if there is to be an international coal situation.

Please don't ask me where I get the fact or the figures, for they are not in the possession of any government and they cost too much money to be otherwise than privately controlled.

But the fact is that in normal times the United States has a 20 per cent. surplus coal capacity. Now as the production in the United States is twice that of Great Britain, the United States has normally a coal capacity that is 40 per cent. of the strained and maximum coal capacity of Great Britain.

Definite Program for American Shipping

Declaring for private ownership and operation of the American merchant marine, with Government control of the maximum rates to be charged American shippers, the American Manufacturers' Export Association has adopted resolutions which outline a practical plan for utilizing the $2,500,000,000 fleet which the country will own at the end of 1920.

In February Senator Ransdell, in a speech before the Senate, called upon the business men of the country for concrete suggestions as to the disposition and operation of the vessels which the nation has built or is building. In that speech he stated that at the end of 1920, if present plans were carried through, the United States would have expended $2,500,000,000 for Government-owned boats, and would have a total tonnage of 19,000,000 under the American flag. He declared that thus far no definite program had been adopted for utilizing this immensely valuable national asset.

The views of the exporting manufacturers who must use these vessels are expressed in the resolutions of the American Manufacturers' Export Association, which comprises 1200 of the larger manufacturers throughout the country. As adopted by the Board of Directors of the Association the resolutions read as follows:

"The nation's foreign trade cannot be successfully developed without an American merchant marine able to transport American products as cheaply, as regularly and as efficiently as products of other countries are carried.

"Our naval authorities have declared that both for the training of American seamen, and for the necessary victualing and sup-

plying of the Navy when operating in foreign waters, an auxiliary merchant marine is essential. In fact, the Secretary of the Navy, in a letter to this Association, said: 'I feel that the proper enlargement, the influence, and the wise use of such a merchant marine is the biggest question now to be solved by the American people.'

"The establishment and maintenance of an American merchant marine is therefore a matter in which every citizen of the country is vitally interested.

"Be it resolved therefore that the Board of Directors of the American Manufacturers' Export Association, after consideration of the problem, recommend the following means of utilizing the ships now built and building by the United States Government to the end that a permanent and available American merchant marine may be established.

"First—All ships owned by the United States Government or building or contracted for by the Government, should be sold to American ship operators at the earliest moment after proper basis for such sale can be established.

"Second—The price at which these ships are sold should not exceed the cost of foreign-built ships of the same class and tonnage.

"Third—The Government should exercise control to the extent of establishing maximum rates.

"Fourth—Some guaranty should be given to operators of American ships that under certain conditions and for a limited time they will be reimbursed for losses sustained in handling business at competitive rates where the revenue is not sufficient to cover operating cost."

The provision that private ship operators must be guaranteed against operating at a loss on rates fixed by the Government is based, it is explained, upon the fact that our present navigation laws compel the payment of higher wages upon American ships than are paid on the ships of any other nation.

Furthermore, to properly expand the country's export trade, new ocean routes must be established which cannot be profitable until a larger volume of trade has been built up.

The Export Association would guarantee private ship owners against loss while these conditions continue, but its resolution is framed to prevent a subsidy resulting in excessive profits. Private operators, under this last provision, would be guaranteed against unavoidable losses, but their profits would still depend solely upon their own efficiency and enterprise.

Italy's Coal Needs

That Italy needs 200,000 tons of semi-bituminous coal from the United States each month for at least a year, and that American coal producers have an opportunity to continue to hold whatever trade it may secure, is the declaration of Francesco Quattrone, the High Commissioner for Italy in this country.

Mr. Quattrone also stated there was no truth, so far as he knew, in the dispatches received in this country to the effect that Italian orders for 4,000,000 tons of American coal had been placed and that shipments were to begin shortly. He believes, however, that there is a splendid opportunity for operators in this country to secure new markets and that the coal is sadly needed if Italy is to meet the reconstruction period successfully.

The fuel situation in Italy is serious. Owing to conditions in England, that country finds it impossible to supply Italy with fuel as in former years. Italy is unable even to get sufficient coal to meet her minimum requirements for the railroads and industries, the normal needs being about 1,000,000 tons a month. At present there are no supplies of coal on hand, factories are suffering from the lack of fuel, while other industries are partially closed down.

Every effort is being made to meet the situation by encouraging the production of lignite and the burning of the best woods of the forests, which will of necessity create a shortage of lumber for building purposes.

During the war, said Mr. Quattrone, it was recognized that Italy could not afford to have less than 600,000 tons of coal a month. This tonnage was kept up for some time, but for the past several months has shown a decrease, so that in March of this year less than 400,000 tons were received.

The ports of Aveiro and Caminha, which had been closed by order of the Portuguese Government, have been reopened to navigation.

United States May Become Largest Coal Exporter

The serious complaints of a coal scarcity in Great Britain coupled with the proposition recently presented in Parliament for an investigation by a commission to be created by the King lends interest to figures compiled by the National City Bank of New York regarding the world's coal production in the last half century and the relative share of Great Britain and the United States therein.

The figures show that the coal output of great Britain grew from 124,000,000 short tons in 1870 to approximately to 255,000,000 in 1918, while the output of the mines of the United States grew from 33,000,000 tons in 1870 to 685,000,000 tons in 1918. The British output in 1918 was double that of 1870. The United States output in 1918 was 23 times as much as in 1870. In all parts of the world aside from Great Britain and the United States, the output grew from 80,000,0000 in 1870 to 500,000,000 tons in 1918, or about six times as much in 1918 as in 1870.

The United States produced about 14 per cent. of the world's output of coal in 1870, 80 per cent. in 1880, 28 per cent. in 1890, 32 per cent. in 1900, 39 per cent. in 1910, 48 per cent. in 1918. Curiously, however, the United States, although turning out two and a half times as much coal as Great Britain, has not been until very recently an exporter, in any considerable sense, of coal. Our exportation of coal had never reached as many as 20,000,000 tons prior to 1913, and even in the highest war record of exports only reached 26,000,000 tons in the fiscal year 1918, the highest record ever attained. On the other hand Great Britain's exportation of coal was in 1913, 72,000,000 tons, or nearly four times as much as that of the United States in that year, in 1910 62,000,000 tons against 13,000,000 tons exported by the United States.

Growth in production in very recent years has been much more rapid in the United States than in Great Britain or Germany, or in fact any other part of the world. Our own production of coal, according to the bank's statement, grew from 270,000,000 tons in 1900 to 685,000,000 in 1918, while that of Great Britain was, in 1900, 252,000,000 tons, and in 1918, 255,000,000 and that of Germany 165,000,000 tons in 1900 and 260,000,000 in 1915, the latest year for which figures are available. In the remainder of the world output in 1900 was only 160,000,000 tons, and in 1918 230,000,000 tons.

The possibility of the United States becoming a large exporter of coal and perhaps the world's chief coal purveyer looks comparatively easy when the relative supply of coal is compared in the various sections of the globe. The world's total available stock of coal is 7,397,553,000,000 metric tons, of which the United States has 3,838,657,000,000, or 52 per cent. of the world's total. Canada ranks next to the United States, with 1,234,260,000,000 tons; China, 995,587,000,000; Germany, as it existed in 1913, 423,356,000,000; Great Britain, 189,533,000,000; these figures being supplied by the Geological Congress held at Toronto in 1913.

Miscellaneous Notes

The National Bank of Denmark is raising its discount rate from 5 per cent. (at which rate it has been since July, 1915) to 5½ per cent.

Coal cargoes passing through the Panama Canal during the week ended Mar. 15 are as follows: Norfolk to Pearl Harbor; Norfolk to Arica; Norfolk to Puget Sound; Philadelphia to Pearl Harbor; Norfolk to Antofagasta; Kingston to Callao.

Copenhagen harbor authorities are proposing a budget for 1919 in which the fees are to be increased to cover the expenses. The 100 per cent. increase now applying will be in force for all of 1919 for all fees levied on imported goods, while the increased quay and mooring fees will only be maintained provisionally for six months of 1919. It is estimated that at the end of 1919 the harbor authorities will have a cash fund of over $6,000,000.

Industries in Greece were severely crippled during the war for want of fuel and labor. They have, however, during the months of December, 1918, and January, 1919, received a stimulus in the freeing of some coal and other fuel by the local ministries and in the granting by the military authorities of long leaves of absence to mobilized men.

Coal and Coke Exports in February

Exports of coal and coke, as reported by the Department of Commerce for February, 1919, and the figures for February, 1918, as finally revised, are as follows:

(In Tons)	February 1918	February 1919
Coal		
Anthracite	227,319	221,018
Bituminous	919,999	713,951
Exported to:		
Italy	1,000	4,933
Canada	578,442	446,429
Panama	42,332	8,661
Mexico	12,967	5,142
Cuba	145,104	40,644
Other W. Indies	13,313	16,965
Argentina	22,609	38,993
Brazil	64,747	67,825
Chile	.....	49,056
Uruguay	2,755	12,007
Other countries	36,730	23,296
Coke	83,758	48,806

All imports of coal during February were from Canada. They aggregated 55,834 tons.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Mar. 31 states that freight market conditions have not altered during the week under review.

The Chartering Committee's rates are as quoted below:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge. Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis., or $21 net, 600 tons dis.; Buenos Aires, $18.50 net, 600 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.50 net, 500 tons dis. To Nitrate Range, $16.50 gross prepaid.

Sail (maximum)—Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net.; Santos, $19.50 net; Rio Grande do Sul, $21.50 net, 400 tons dis.; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. To Nitrate Range, $16.50 gross prepaid.

England Losing Coal Contracts

Considerable comment has appeared in both the American and British press relative to the recent American contracts for export coal. Before the war England was able to sell coal far more cheaply than could the United States, not only in Europe, but in America. At the present time several large coal buyers who formerly purchased Welsh coal, are giving their orders to American firms. Thus, Teneriffe has contracted for 100,000 tons of American coal; Italy for 80,000 tons; France, 50,000 tons; and the Swedish Government 250,000 tons for the state railways.

It is said that the Central Brazilian Railway Co. has bought 600,000 tons of American coal at 144 francs ($28.80) a ton, which is reported to be below the present English price.

Would Embargo United States Coal

A deputation from the Nova Scotia Federation of Miners, it was announced at Halifax, N. S., on Mar. 31, will wait on the Government authorities at Ottawa soon to discuss with them the feasibility of placing an embargo on United States coal. Owing to lack of ships, several Nova Scotia mines have been closed and considerable unemployment is reported to exist, it is said, because of the curtailed market due to loss of the bulk of the St. Lawrence coal trade to American operators.

American bituminous coal is now said to be finding its way into New Brunswick through Quebec. At a recent informal conference between miners' delegates and members of the legislature, it was stated that the Nova Scotia coal mining situation had reached an acute stage.

COAL AND COKE NEWS

EDITED BY ALEX MOSS

Harrisburg, Penn.

Recognizing the demand from large employers of labor that ample time should be given for consideration of the many proposed changes in the Workmen's Compensation law, Harry A. Mackey, chairman of the board which framed the draft of the bill, at the opening of a meeting held on Apr. 1, announced that any public discussion of the merits of the bill at this time would be deemed unfortunate, for the reason that it might lead to acrimonious debate, eventuating possibly in serious misunderstanding.

The sensational statement was made at the conference, just before an agreement was reached, to hold another meeting to discuss the matter on Apr. 15, that Pennsylvania mines might be compelled to suspend operations unless the Federal Government shall change its plans for dealing with coal-producing companies. Henry I. Wilson, representing the Central Bituminous Operators' Association, asked for time to figure out what the amendments would cost the operators, and in this he was joined by the Pennsylvania Manufacturers' Association and Henry A. Gordon, of Wilkes-Barre, representing the anthracite operators. The labor people were against granting an extension of time.

In a statement issued Apr. 4 Governor Sproul declared that after a study of the anthracite situation, including the wage question, railroad rates and conditions in general, he had come to the conclusion that the increase of 10 cents a ton for five months beginning May 1, recently announced by the operators, is justified.

The governor attacked railroad rate inequalities, gave figures showing the cost per long ton of coal delivered on trestles in several eastern Pennsylvania cities, and said that the advance was necessary in order to maintain the wage schedule for miners and to prevent derangement in the trade. The governor also advocated the establishment of municipal fuel markets for the sale of coal at cost.

Uniontown, Penn.

Brought back to life after having been permitted to lapse for the duration of the war, the Coke Producers' Association, an organization of 35 merchant operators of the Connellsville field, is giving promise of growing into an active agency through which the Connellsville coke region may be represented in matters pertaining to the entire coke industry. The crisis in the present industrial uncertainty has resulted in binding the operators together into a compact body for their mutual benefit in working out a solution best applicable to the coke industry.

That solution is now being sought through a series of almost daily conferences among the region's leading producers. Virtually all of the largest independent operators have offices in Uniontown, or have representatives here, and it is a simple task to call them together in conference. It is expected that within a week or ten days a definite statement will be made by an appointed spokesman of the organization outlining the conclusions reached at the conferences.

Coal shipments down the Monongahela River during the first three months in 1919 almost doubled those of the corresponding period in 1918. The shipments for March alone were 24,274,000 bushels, an increase of 4,000,000 bushels over January and February. Combined, the shipments for the three months were 67,715,000 bushels as against 35,477,000 bushels during the first three months of 1918.

Charleston, W. Va.

Decreases in production during the last week in March featured mining conditions in West Virginia, these being traceable directly to embargoes which shut off the shipment of coal from the New River, Pocahontas and Fairmont regions. Indirectly, of course, there were slight decreases due to the general condition of the market. In contrast to conditions affecting eastern shipments was a perceptibly steady improvement in the demand from the west, as seen in an increased production in fields essentially engaged in shipping coal to that consuming area. The increases did not average over 3 or 4 per cent., but were highly encouraging.

Taking the state as a whole, production was much under 50 per cent., and mines were not operated as a general average more than two days during the week. Of considerable help in keeping up production were heavy navy shipments. While transportation facilities were much improved over the earlier part of March. the labor shortage became a little more pronounced, though not sufficient to interfere materially with production under present circumstances.

West Virginia producers are looking forward to the opening of the lake season by Apr. 15, when they anticipate an increased production. Renewal of contracts and the signing of new contracts, effective Apr. 1, is counted upon to give impetus to production in all the fields of the State.

Victoria, B. C.

"This year the coal mines of the northwest will not operate 40 per cent. of the time, which means a heavy expense for operators," stated James S. Ramage, head of the Continental Fuel Co. and the Hawkeye Fuel Co., recently in Spokane. "For some time," he continued, "there has been serious over-production of coal in Canadian and other districts from which Spokane City receives its supply. About 80 per cent. of the steam coal used here comes from the Canadian mines, and a serious situation has developed in that country as is evident by a recent report issued by the Workmen's Compensation Commission making the definite statement that cost of labor in producing coal is $2.60 a ton, which is above previous calculations and more than in other fields with which Canada competes."

As to the situation in western Canada in regard to coal production and trade, it is interesting to note the comments of Premier Charles Stewart, of the Province of Alberta, made recently to the Legislative Assembly of that Province. He pointed to the stored up surplus of 2,000,000 tons of coal and admitted that the position was a serious one, especially with the embargo taken off American coal and with production costs at a high level. The premier declared that the only solution of the problem was the reduction in the price of coal to the extent of at least $2 a ton, in order that American competition might be met. This reduction, he said, had to be achieved by cutting the price of production, though some slight decrease might be attained in freight rates. He believed that the difficulty might be remedied, at least in a degree, by lengthening the time of production, assuring the miners of steady work for a period of eight months in the year instead of but six months as at present. While Premier Stewart declared that he was against cutting wages, his remarks led to the conclusion that, with the lengthening of the period, the miners' daily wage would have to come down. He virtually admitted, however, that the Alberta Government was helpless in face of present conditions.

New York, N. Y.

The strike of harbor workers appears to be as far from settlement as ever. As a result of a conference held last Saturday night in the Hotel Manhattan between representatives of the Boat Owners' Association and the strikers' representatives, it was decided that the strikers' organizations would on the following Monday vote on a proposition involving an increase in wages, said to be 15 per cent., and a 10-hour day. The original demands included a larger increase in wages and an 8-hour day.

When the vote was announced late on Monday of this week it showed that the proposition was rejected by a vote of 300 to 29, the majority holding out for an 8-hour day. Several meetings have been held during the week but the strikers appear to be "standing pat" for at least the shorter working day.

The breach between the Tidewater Boatmen's Union and the remaining organizations in the Marine Workers' Affiliation seems to be broadening. The former organization accepted the terms of the boat owners early last week and broke away from the Affiliation.

The failure of the men and employers to come to an agreement concerning their difficulties is likely to prove serious to coal consumers here, should it continue much longer. With the decision of Governor Sproul of Pennsylvania sustaining the producers' announcement of an increase in prices it is expected that users of coal will want their next winter's supply put away.

It is expected that representatives of the United States Department of Labor, who have been endeavoring to bring about a settlement, will now make further efforts to effect an agreement and insist that the owners and strikers should consider the public and come to terms.

PENNSYLVANIA

Anthracite

Shickshinny—The Stackhouse Coal Co. on Apr. 1 ceased work for thirty days to permit the company to make needed repairs to the machinery. Several hundred men and boys will be thrown out of work.

Kulpmont—The Susquehanna Collieries Co.'s mammoth breaker at Scott colliery was menaced by fire which destroyed the carpenter, machine, repair and blacksmith shop immediately adjoining the breaker. The fire, caused by defective wiring, was discovered by a night watchman.

Peckville—The Mount Jessup Coal Co. has brought suit in equity against the Winton Coal Co. for an injunction restraining the latter from carrying out an alleged forfeiture of mining rights. In the bill the Mount Jessup company states that during the past ten years it has paid to the Winton concern, lessors of the tract, $393,961.88.

Coleraine—While mining conditions at present are slack, anthracite operators are preparing for a return of brisk times in the market. The Beaver slope of the E. S. Van Wickle Estate Co., abandoned 25 years ago, and filled with water ever since, is being pumped out. The coal remaining will be removed.

Plains—Alleging that the defendant company mined, removed and sold over 125,000 tons of coal of small sizes and failed to account therefor, heirs of the estate of J. Robinson Williams have brought suit in equity against the Lehigh Valley Coal Co., in which they ask the court to decree an accounting for all moneys withheld. The suit is based on a coal lease made in 1872.

Shamokin—Sparks from a motor-driven generator set fire to the engine house of No. 6 slope, Hickory Ridge Colliery, operated by the Susquehanna Collieries Co., on Apr. 1, completely destroying the building and ruining the big motors used in hoisting coal from the mine. Several hundred men and boys have been thrown out of employment.

Raven Run—Under the direction of several state mine inspectors and mine officials, every effort is being made to get control of the fire raging in the Girard Mammoth Coal Co.'s mine. Concrete barriers have been constructed, sealing that portion of the mine on fire and cutting off the air currents. By this method officials hope to confine the blaze to the slope workings in which it started. For some time, a culm bank has been burning near the mine, and all efforts to extinguish it have been of no avail. It is thought that when the wind was blowing with the force of a gale on Mar. 27, the fire was carried down an old slope into the mine, where workmen discovered that the coal had ignited.

Pottsville—The Philadelphia & Reading Coal & Iron Co. is planning to apply to the United States Supreme Court to appeal from the decision of the local referee awarding the sum of $5800 to Mrs. John Hancock as compensation for the death of her husband, which occurred near Locust Gap. Mr. Hancock was employed upon a trip between the Locust Gap colliery and

the road at Locust Summit, over which the coal from the colliery is shipped to Shamokin scales. It is held by the company that Mr. Hancock was engaged in interstate commerce in his employment, and it is contended by the attorneys for Mrs. Hancock that the coal was not in interstate commerce until reclassified at the Shamokin yard. It is noted that thus far every court, including the State Supreme Court and the State Compensation Board, has decided in favor of Mrs. Hancock as regards this very fine legal point.

Bituminous

Brownsville—The H. C. Frick Coke Co. has closed down its Fairchance coal and coke plant, located near here, indefinitely.

Brinkerton—The H. C. Frick Coke Co.'s stables at the Mutual No. 4 mine at this place were entirely destroyed by fire the night of Mar. 30, causing a loss estimated at $15,000, partially covered by insurance. Thirty-two horses perished in the blaze, only two animals being rescued. The fire is believed to have been of incendiary origin.

WEST VIRGINIA

Charleston—The Gallatin Mining Co., which has been operating on Wet Branch of Cabin Creek in the Kanawha County field under a lease from J. C. Blair, has subleased the plant to the Wet Branch Mining Company.

Welch—Develcpment work will be undertaken in the near future or as soon as circumstances seem favorable, by the Pulaski Iron Co. on holdings of the company near this place. Percival Johnson, of Pulaski, Va., is the general manager of the company.

Huntington—The Logan Fuel Co., recently chartered, expects to confine its activities for the present to the sale of coal produced in the Thacker, Logan, Kanawha, Pocahontas and New River fields. A. H. Land has been elected president of the company. Others interested are L. B. Ramsey and C. H. Land, the latter of the First National Bank of Logan.

Fairmont—Affairs of the defunct Dakota Coal Co. were wound up when the trustees in bankruptcy of that company presented their report to the former stockholders of the company and paid over $5000 to the stockholders, the bankrupt company thus being able to meet more than all its outstanding indebtedness. This, however, became possible through the purchase of the plant and assets of the company some time ago by the Jamison Coal and Coke Company.

Fayetteville—Work has been started on the plant of the Simrall Coal Co., chartered a month or so ago, a force now being engaged in grading for a sidetrack to the company property in the Winding Gulf field in Raleigh County, where the company has two seams awaiting development —the Beckley and the Pocahontas—surveys of the property having been completed. A number of miners' dwellings will be erected between now and the first of the year, when the company expects to begin operations. Dr. Gory Hogg is president of the company; P. M. Snyder, vice president, and F. D. Drumheller, secretary-treasurer. Among others interested is S. A. Scott of the New River Company.

Morrisville—The Rich Block Coal Co. has changed hands, Charles H. Bronson, J. L. Broh and others of Huntington having acquired the property and assets of the company, the plant being located near here. The officers are: Charles H. Bronson, president; I. J. Rhodes, of McDowell County, vice president; H. L. Broh, of Huntington, secretary-treasurer. The Rich Block Co. originally represented the investment of Roanoke men, having been placed in operation about two years ago. The plant was shut down on Jan. 1 and since that time has not been in operation. Just as soon as a number of improvements contemplated are finished the company hopes to be able to start operations again and on a larger scale than has heretofore been the case.

KENTUCKY

Hellier—The Allegheny Coal and Coke Co. is understood to have completed plans for the construction of the proposed new coal tipple at its plant.

Lynch—The United States Coal and Coke Co. at this place is increasing its development in order to ship 300 cars of coal daily to Gary, Ind., for the United States Steel Corporation.

Hazard—A slate slide in the mine of the Midland Mining Co., on Lotta Creek, resulted in the death of two miners, who were working on the face of a seam. Two other men in the same room were uninjured.

ILLINOIS

Auburn—An explosion in which two miners were killed, occurred early Saturday morning, Mar. 29, at the Panther Creek mine at this place.

Taylorville—Mine No. 8 of the Peabody Coal Co., located here, has been closed for two weeks during which time the machinery will be completely overhauled. About 500 men are temporarily thrown out of employment.

Maryville—The water train on the Troy & Eastern R.R., which supplied the Donk Bros. mine here, has been taken off because the mining company has laid a pipe line to a spring half a mile away which gives promise of supplying all the water that is needed.

Matherville—The mine of the McCraney Sand and Gravel Co., of Rock Island, Ill., has closed down, all the coal having been worked out. It is probable that the tipple will be taken down and moved away. About 25 men were employed in the mine when it closed.

Duquoin—Work has been started on the reopening of the old Barwell mine, which is located on the Wabash, Chester & Western R.R., west of here. Operations are being pushed by a new concern known as F. Soper & Co., of Cutler. The mine was abandoned some time ago, and it will be a long while before the mine is in working condition.

Belleville—State Mine Inspector Wright has filed suit in the court of Justice Wangelin against the St. Louis & O'Fallon Coal and Mining Co., alleging that it has violated the state mining law by failing to provide an adequate washhouse at the so-called Nigger Hollow Mine No. 2, and failing to provide water under proper conditions. The mine employs between 500 and 600 men.

Carlinville—For the second time in a month the record for coal hoisted in a day was broken Saturday, Mar. 29, at the Standard Oil Co. mine here. The day's hoist was 1212 loads, or 968 tons. The mine is being operated every day. Coal is also being produced at the Standard mine at Berry, and the finishing touches are being given to the installation of machinery. Coal is being taken from both the main shaft and the air shaft of the big mine at Shafer, which, when all the machinery is installed, will be the largest producer in the world.

Valier—The village of Valier, east of Duquoin, is rapidly developing into a thriving mining town as a result of the construction of what will be one of the largest mines in the state when completed. The mine, which is on the Burlington R.R., and is owned by that company, was started about a year ago. At the present time several hundred tons of coal are being hoisted each day from the air shaft, while a new steel tipple is being erected at the main shaft. New houses have been built in the town, and at the mine one engine-house, supply-house, washhouse and office building have been finished. A hospital will be erected at the mine in the near future.

TEXAS

Rockdale—The Federal Fuel Co. is understood to be arranging plans for the early commencement of work on the development of a total of about 1400 acres of lignite coal properties in the vicinity of Rockdale, the works to have a capacity of about 1000 tons daily. Headquarters of the company are in the Scanlon Building, Houston. Henry G. Butler is vice president and general manager.

COLORADO

Trinidad—An explosion in the Empire mine of the Empire Coal Co., near Aguilar, on Mar. 31, caused the death of eleven men. At this writing rescue crews are searching for two additional bodies believed buried. Six bodies have been brought to the surface and the bodies of five other dead have been located. Of 36 men who were in the mine when the explosion occurred, 23 made their way out through a connecting shaft.

OREGON

Marshfield—The Southern Pacific Company, which has recently purchased the Beaver Hill coal mine, plans developments to increase the coal output.

Foreign News

Merritt, B. C.—Work has been resumed at the Diamond Vale coal mine.

Personals

George Ing, engineer of the Black Diamond Coal Co., Marion, Ill., has resigned to accept a similar position with the Bell Coal Co. at Zeigler, Illinois.

R. E. McLain, until Jan. 15 superintendent of the Hewittville mine at Stonington, Ill., has been appointed superintendent of the Peabody mine at Stonington, succeeding Superintendent Anderson, who goes to Kentucky.

Lieutenant-Commander H. J. Elson, U. S. Naval Reserve, has been released to inactive status and has resumed his civilian work as secretary and treasurer of the Walter A. Zelnicker Supply Co., of St. Louis, Mo., with which company he was in charge of internal management and manufacturing operations.

E. C. Cherrington and **T. R. Cooley,** who for the past few years have been in the sales service department of the Cutler-Hammer Manufacturing Co. at Milwaukee, have been transferred to the Pittsburgh office of the central district, Mr. Cherrington becoming office manager and Mr. Cooley, engineering correspondent.

Lieut. A. Koenig, of the coast artillery, has been discharged from the service and has joined the forces of the Advance Machinery and Supply Co., Denver, Colo., as sales engineer. Lieutenant Koenig graduated from the Electrical Engineering Department of the University of Colorado in 1913 and has spent about four years in the employ of the General Electric Co., Schenectady, N. Y. The last two years of this time was spent in the Experimental Department.

Charles L. Smith, who has become associated with the newly formed St. George Coal Co., 149 Broadway, New York City,

CHARLES L. SMITH

was connected with Whitney & Kemmerer for 12 years. Mr. Smith came to New York from Pittsburgh in 1899 and became associated with J. Samuel Smoot, now a vice president of Burns Brothers. He remained with Mr. Smoot until 1907, serving as Deputy Commissioner of the Coal Merchants' Association of New York the last three years of that time, Mr. Smoot at that time being the Commissioner. During his connection with Whitney & Kemmerer Mr. Smith was city salesman for that concern and has been largely interested in the trade of large steam consumers. In addition to his other duties, Mr. Smith has for 15 years been the eastern representative of the *Retail Coalman* of Chicago.

Obituary

E. B. Sturgis, president of the Pinehill Coal Co., with offices at 17 Battery Place, New York City, died Tuesday, Apr. 8, at his home in Scranton, Penn. He was in his 74th year and had been in the coal business for upward of 50 years.

William Clayton, a pioneer coal operator of Illinois, died a few days ago at the home of his son, Thomas Clayton, near Collinsville, Ill. He was 80 years old. Thirty-five years ago he sank the first mine shaft in the vicinity of Collinsville. This was followed by another. Both mines were sold to the Consolidated Coal Co., of St. Louis. He was born in England, but came to America in 1863. Until the war prevented he made an annual trip to England. His last voyage was made on the "Lusi-

tania" a few months before it was sunk. Since he retired from mining he has lived on a farm.

Coming Meetings

Illinois Mining Institute will hold its annual meeting May 22, 23 and 24. Secretary, Martin Bolt, Springfield, Ill.

National Coal Association will meet May 21, 22 and 23, at Congress Hotel, Chicago, Ill. Secretary, J. D. A. Morrow, Washington, D. C.

International Railway Fuel Association will hold its annual meeting May 19-22 at the Hotel Sherman, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

Indiana Retail Coal Merchants' Association will hold its annual spring meeting Apr. 23 and 24 at Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind., subject to ratification of executive committee. Secretary, J. W. Paul, Pittsburgh, Penn.

American Manufacturers' Export Association will tender a luncheon at 12:30 p.m., to all its members who may be in attendance at the National Foreign Trade Convention in Chicago, Apr. 25 to 26, at the Congress Hotel.

Kentucky Mining Institute after having skipped two years, one on account of the war and the other due to the influenza epidemic, expects to hold its annual meeting this year. While the date and place of meeting have not definitely been set, it will probably be held on May 30 and 31 at Lexington, Ky. Secretary, C. W. Strickland, Huntington, W. Va.

C-H Wiring Devices—Push Button Specialties. The Cutler-Hammer Manufacturing Co., Milwaukee, Wis., Catalog. Pp. 64, 8 x 10½ in., illustrated. Lists describe and give prices of a full line of push-button sockets.

Plymouth Gasoline Locomotives. J. D. Fate Co., Plymouth, Ohio. Catalog No. 4. Bulletin O. Pp. 8, 8½ x 11 in., illustrated. Gives views of these motors in use at the coal mines and quotes from the testimonials of a number of large operators.

Wheeler Steam Jet Air Pump. Wheeler Condenser and Engineering Co., Carteret, N. J. Premliminary Bulletin No. 113. Pp. 8, 8 x 10½ in.; illustrated. Explains the operating principles of the pump and gives reasons for high efficiency. The inter-condenser is minutely described. The pump is applicable to jet condensers as well as to surface condensers.

Industrial News

New York, N. Y.—Charles F. Ames & Co., Ltd., 90 West St., have been appointed to act as the New York sales department of the Platt Iron Works, of Dayton, Ohio, manufacturers of pumping and power plant equipment.

Chicago, Ill.—F. V. Sargent has been appointed by the Chicago Pneumatic Tool Co. as district manager of sales in the Boston territory, succeeding F. S. Eggleston. Mr. Sargent's headquarters will be at 182 High St., Boston, Mass.

Charleston, W. Va.—Further development of Elk River territory is indicated by the execution of a lease on 113 acres from E. J. and W. E. Thomas to J. G. Vaughn, and should conditions become propitious further plans will be made for mining coal.

Orange, N. J.—The Edison Storage Battery Co. has a new price list, effective Mar. 1, 1919, reducing the price of type A, B and G Edison cells approximately 16 per cent. This company is also boosting prosperity by using the slogan: Procrastination murders industry—stir things up!

Wilmington, Del.—E. I. Du Pont de Nemours announces that effective Apr. 1, T. E. Doremus has been transferred to the E. I. Du Pont de Nemours Export Co. as general eastern manager, with headquarters in Shanghai, China. E. R. Galvin has been appointed manager of the sporting powder division to succeed Mr. Doremus.

Petros, Tenn.—The State Board of Control has recently awarded contracts for the furnishing of the necessary washing machinery, conveying and elevating equipment, belting, etc., to be used in connection with the construction of the new coal tipple at its Brushy Mountain mines, to replace the structure recently destroyed by fire.

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces the discontinuance of its office at Wichita, Kan., and the transfer of stock to Eldorado, Kan., where an office and warehouse have been established. The company also announces the opening of a new office at Tulsa, Okla., 313 Richards Building, with warehouses at 102 No. Cheyenne Street.

Louisville, Ky.—Western Kentucky coal operators have petitioned the Louisville District Freight Traffic Committee for establishment of a rate of $1.35 from the section to Camp Taylor, at Louisville, as against a present rate of $1.40 to $1.60 per ton, and further requests that the rate of $1 per ton from southern Indiana be raised to $1.35, alleging that discrimination is now practiced.

Buffalo, N. Y.—Work on the byproduct plant of the Donner-Union Coke Co., which was suspended when the armistice was signed, has been resumed, the Government taking part. A large force is employed, but the work will take several months. The plan is for the Bonner and Union furnaces in the city to use the coke in their furnaces here. It is reported that the coke ovens of the Lackawanna Steel Co. will also be rebuilt.

Morgantown, W. Va.—The Department of Mining, West Virginia University, has issued a poster descriptive of its short course in coal mining, which begins June 16 and ends July 26, 1919. At the close of the course the State Mining Department will conduct an examination for mine foreman and fireboss certificates. The poster is quite complete with information. It contains the list of subjects to be taught during the course and gives the schedule of classes.

St. Louis, Mo.—The Standard Rail and Steel Co. announces that I. H. Cohn, formerly of the National Steel Rail Co., has become associated with the company and will be in complete charge of the rail department, handling all matters relative to relaying rails and railroad equipment. The modern plant of the company in Madison, Ill., is now nearing completion. On and after Mar. 31, 1919, the company will occupy Suite 1108-1115, Boatmen's Bank Building, St. Louis.

Charleston, W. Va.—The Lewiston Black Coal Co. will hereafter conduct operations on a more extensive scale at Seth, Boone County, where the plant of the company is located, this operation being on Coal River. The capital of the company has been increased to $100,000. It is proposed to install an electric power plant and electrical machinery throughout, giving the plant a capacity of about 140,000 tons a day. Coal will be mined in the Cedar Grove seam, which at this company's mine is about 5 ft. thick.

Cumberland, Md.—The statistics of the Cumberland coal trade for the year 1918, recently compiled from official sources by the auditor's office of the Cumberland & Pennsylvania Ry., Cumberland, shows a total production of 7,122,441 tons for the Georges Creek and Upper Potomac region in West Virginia. Of this amount 3,205,500 tons were from the Maryland or Georges Creek field and the remaining 3,916,551 tons from the Upper Potomac field. The total output of the two fields has been exceeded in only three previous years—1906, 7,188,033 tons; 1907, 7,360,336 tons; 1910, 7,148,968 tons.

Morgantown, W. Va.—Weather conditions permitting, there will be no further delay in the completion of the Indian Creek & Northern R.R., a coal-carrying road which is being built into the Empire tract in Monongalia County in order to permit the New England Fuel and Transportation Co. to open mines and develop its large holdings in the county. It will require five months to complete construction work started last year, but which was suspended during the winter months. The coal company is going ahead with its work of making openings and getting ready for operations on a very large scale.

Jefferson City, Mo.—The lower House passed the Washhouse Bill on the fourth instant. This bill, which requires all mining companies in the State of Missouri to provide hot and cold water showers for their employees, is one that prevails in nearly all the mining states, with the exception of Missouri. The bill will work a hardship on many of the mining companies, for all companies that have more than five employees come under the law. There are a lot of little strip mines and little drift mines that will evidently have to close down because they cannot stand the expense. A large number of these mines are what is known as "local mines," which provide coal for the little communities close by in the winter months.

St. Louis, Mo.—The Interstate Commerce Commission, in a brief forwarded by Joseph W. Folk, general counsel of the St. Louis Chamber of Commerce, is asked to throw out in its entirety the report recently filed by Examiner Mackley, which held that the bridge arbitrary of 20c. a ton on coal transported from East St. Louis to St. Louis is justified. The examiner's report, he declares, is based on erroneous assumptions and erroneous conceptions of law. He asks that the Commission require the railroads to make and maintain a basis of group rates from the Illinois mines to St. Louis, East St. Louis, Dupo, Venice, Madison and Granite City, composing the St. Louis industrial district. In his brief Folk takes 25 exceptions to the findings of the examiner. The arbitrary has been in dispute for several years, and has been in litigation and before the Interstate Commerce Commission much of the time.

Weekly Review

Railroad Fuel Controversy Still at Its Height—Buying of Bituminous Still of a Desultory Character—Contract Business Being Closed—Best Grades of Soft Coal in Demand —Anthracite Investigation Discloses That Price Increase Was Justified

OF CHIEF interest in the coal situation during the past week was the turn of events in the railroad fuel controversy. The Railroad Administration has come out flat-footed against a price-fixing program. Until this vexatious question is settled the general market cannot be said to be on a firm basis.

The efforts of the Industrial Board of the Department of Commerce to promote business activity by stabilizing prices have, by the attitude of the railroads, been brought to naught. The steel men, who had taken it for granted that the Railroad Administration would purchase rails after they had reduced prices from 10 to 14 per cent., are now disillusioned. The coal men, when approached by the Industrial Board with a similar proposition to fix coal prices, profiting by the developments in the steel situation, demanded assurances that the Railroad Administration and other Government departments would buy coal at the prices agreed upon. Chairman Peek, of the Industrial Board, upon taking the matter up with Director General Hines was informed that the railroads insisted upon purchasing coal in their own way and at their own price.

Stripped of all camouflage, this means that the railroads insist that coal be sold to them below the cost of production, and that the public be made to pay more than a just price for the coal it consumes. In other words, the Railroad Administration asks the bituminous coal operators to gouge the public in order that the railroads may purchase their coal supplies at a ridiculous price.

In the meantime the attitude of the Railroad Administration is working the bituminous coal industry a great deal of harm. Large consumers are buying only from hand to mouth, as it were, hoping that the railroads will prove successful in their attempt at beating down prices, and expecting to make the lower prices the basis for much of the now-delayed contract business for the coming coal year. The result is that there is much idle time at the mines. Operators, however, have learned some lessons during the recent war period. They purpose adhering to their policy of selling coal at a reasonable profit—and in this they have the backing of their employees.

Market conditions in bituminous coal show signs of improvement in spite of the many deterring influences, though buying is still on a relatively small scale. The best grades of coal are most in demand, consumers as a rule exercising the keenest sort of discrimination in the selection of fuel to meet their needs. In some cases concessions have been made on coals of medium to inferior grades. Many industries, however, have not yet resumed anywhere near normal activity and will not buy and store coal regardless of price.

Some contracts have been closed for the new coal year by purchasing agents who have carefully surveyed the situation. Labor troubles are impending, a car shortage is almost certain when crops begin to move in the summer and fall, and production of soft coal is lower than ever. In fact, the daily output of bituminous for the week ended Mar. 22 is the lowest recorded during the past three years, the total tonnage mined for the week in the entire United States being 7,599,000 net tons. Consumers who are not covered by contract will find themselves unable to procure all the spot coal they need as the months go by.

Of the utmost importance to the anthracite industry was the statement made by Governor Sproul of Pennsylvania on Apr. 4 that the increase of 10 cents a ton in the price of hard coal beginning with May is justified. It will tend to stimulate buying on the part of consumers who were of the belief that investigation would lead to a charge of profiteering on the part of the operators.

Owing to the lack of demand, the production of anthracite has been decreasing steadily, though the output of 1,437,000 net tons during the week ended Mar. 22 is 216,000 net tons better than the output the week previous. Production at the mines should be stimulated as much as possible during the coming spring and summer months, or else hard coal will be scarce and prices much higher in the fall and winter. Consumers should heed the "Order Early" injunction of Dr. Garfield and lay in their coal supply now.

WEEKLY COAL PRODUCTION

The output of bituminous coal in the United States during the week ended Mar. 29 is estimated at 7,599,000 net tons, as against 7,488,000 net tons during the week ended Mar. 22, and 11,006,000 net tons during the week ended Mar. 30, 1918. The increase during the current week of slightly over 100,000 net tons was slight, and by no means records the improvement which was expected as a result of the "Order Early" campaign inaugurated by the United States Fuel Administration several weeks ago. In fact, the present daily output is the lowest recorded during the past three years. Estimates place production for the coal year ended Mar. 31 at 558,000,000 net tons, which production was approximately 6,300,000 net tons in excess of the output of the coal year 1917-18, or slightly over 1 per cent. During the current week the average production per working day is estimated at 1,266,000 net tons in comparison with 1,784,000 net tons for the coal year 1918-19, and 1,763,000 net tons for the year preceding.

The production of anthracite in the United States during the week ended Mar. 29 is estimated at 1,437,000 net tons, and is a considerable improvement over the output during the week ended Mar. 22, estimated at 1,221,000 net tons. The output of the corresponding week of 1918 was estimated at 2,099,000 net tons. The total production for the coal year to date is estimated at 91,975,000 net tons, as against 99,568,000 net tons during the same period of last year. The daily average per working day during the current week is estimated at 240,000 net tons, and is considerably in excess of the daily average recorded during the past few months.

Carriers' reports for the week ended Mar. 29 show increased loading in all districts with the exception of the southern West Virginia fields, southwestern Virginia and the Iowa, Texas and southwest states. The decreases where they occurred were slight, while in central Pennsylvania there was an increase in loading of 1100 carloads, or approximately 5 per cent., and in Ohio 1200 carloads, or 10 per cent. Slight increases occurred in all other fields.

Bituminous coal shipped to New England by tidewater during the week ended Mar. 29 is estimated at 89,166 net tons, and is a slight decrease compared with the tonnage shipped during the week ended Mar. 22, estimated at 93,376 net tons. Shipments to New York and Philadelphia during the current week were extremely light, amounting to but 14,235 net tons as against 40,432 net tons during the week preceding. Shipments from Baltimore were slightly in excess of those of the week ended Mar. 22, while the tonnage loaded at Hampton Roads exceeded that of the preceding week by 4 per cent.

Total shipments of bituminous coal from all tidewater harbors, during the week ended Mar. 29, are estimated at 402,126 net tons, and exceed the tonnage shipped during the preceding week by approximately 11 per cent. The improvement occurred at all harbors with the exception of Baltimore, where the tonnage loaded amounted to 25,538 net tons, as compared with 32,040 net tons during the week ended Mar. 22.

The production of beehive coke in the United States during the week ended Mar. 29 was extremely low, and the estimate of 365,107 net tons for that week is 39,168 net tons, or approximately 10 per cent., below the production of the week ended Mar. 22, and 244,056 net tons or approximately 40 per cent. below the production of the corresponding week of 1918. For the calendar year to date, the production is estimated at 5,979,152 net tons, as against 7,102,192 net tons during the same period of last year, all states falling behind the output recorded during 1918. The daily average per working day during the current week is estimated at 60,851 net tons, as compared with 78,673 net tons, the daily average for this year to date, and 93,000 net tons, the daily average for the same period of 1918.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running much less, compared with the same week of 1918. Orders from road salesmen for immediate delivery were in smaller volume and commitments for fall were much below the total of the comparative period of last year. Trading is very active but in small lots, and many more merchants were in the market. They report a continuance of excellent retail business. Collections were satisfactory.

Bradstreet's—More irregularity is shown in the general trade and industrial situation with a rather sharply defined difference in the tone of reports from purely distributive trade as opposed to those dealing with big primary lines such as iron, steel, coal and kindred trades. In the former, despite weather irregularities such as rain and snowstorms actual buying of spring goods, men's wearing apparel, clothing, shoes, women's wear in general, millinery, implements and hardware has expanded at many points.

The Iron Age—The second week of the new iron and steel prices has brought little broadening of demand. Inquiries and specifications have increased, but practically all the business offered is still recognized as having been held back awaiting the reductions. The Railroad Administration's refusal to accept the Industrial Board's prices on steel or to be bound by those yet to be fixed on coal and building material seriously threatens the whole stabilizing program, since the railroads would buy normally over 25 per cent. of the country's production of coal and 20 per cent. of its steel. It is not surprising in view of the jumble at Washington, that individual buyers are in no haste to spread sail.

American Wool and Cotton Reporter—The Boston wool market is fairly active and there is still a good demand for fine wools of all kinds. Although it is a bit early for many transactions in the new domestic clip, growers and country dealers are showing a keen interest in prospects. Heavy buying of domestic fleeces is looked for, and some are predicting that the season will open with prices around 40 to 45c. to the growers. Shearing is under way in Arizona, and the cutting of the new clip in eastern Utah and northwestern Colorado started this week. Cotton mill treasurers feel optimistic and several authorities in Boston predict that the mills will soon be in the market for more of the staple. The United States seems to have a splendid future ahead of it in cotton and in other commodities.

Atlantic Seaboard

BOSTON

Somewhat better inquiry. Concessions made for prompt shipment all-rail. Large buyers still withhold purchases. No developments in railroad buying. Differential heavily against distribution inland from tidewater plants. Hampton Roads coals confined to seaboard. No active market looked for until July. Shipping situation not helpful. Railroad-owned barge rates announced. Will help movement over New York piers. Much talk of fuel oil. Reduced rates named on anthracite barges. Fair volume of business for April mining, but demand lacks snap. Light receipts everywhere in March. Retailers advise householders to take on coal. Screenings and steam sizes not so plentiful.

Bituminous—The past week there have been signs of improvement, but buying is still on a relatively small scale. Inquiry for the higher grades all-rail is more noticeable; there is more discrimination than was usual in normal years, and instances multiply where consumers are taking pains to select coals that will meet their individual requirements. This is particularly true among those who have ordinarily used Pocahontas and New River from Hampton Roads. The few coals in central Pennsylvania that have coking qualities are being especially sought by consumers of this kind. A considerable tonnage has been placed in this territory at $3.10 per net ton f.o.b. mines through selling agents who are in position to assure their trade that coal of Navy standard will be furnished.

At the same time, on practically all but the quality grades, there are considerable concessions made to induce consignees to take coal in April and May. Grades that are held with reasonable firmness for contract at $2.95 are being offered for spot shipment at $2.65@2.80, and with little result. In the Fairmont district every effort is being made to get orders for the next 60 days, but the outlook is discouraging so far as New England is concerned. In the Greensburg and Pittsburgh districts there is the same light output and the same pressure on consumers to supply shipping instructions. A few comprehensive orders will soon be in the market, and there will be a great deal of interest in the trade to see whether contracts are closed for season delivery or whether it is decided to buy from month to month as the railroads have begun to do.

Buyers now completely understand the heavy differential that applies against rail-and-water deliveries to inland points. There are industrial centers like Fitchburg, Mass., where reliance was ordinarily placed on water coal via Providence and Boston, but where there is now a freight rate inland from Boston of $1.40 besides a largely increased charge at the rehandling point. It is a foregone conclusion that Hampton Roads coals will have no chance whatever this year to meet all-rail competition at such a point, or even at Lawrence, Mass., where the rate from Boston is $1.05. Current prices at Boston are $7.50@7.75 on cars, while to most points the all-rail rates are $3.20@4 from central Pennsylvania. It is easy to see therefore that Hampton Roads coals this year will be pretty generally confined in this territory to a fringe along the seaboard. At present minimum freights from Norfolk or Newport News the quality of Pocahontas and New River will doubtless hold such tonnage, but the loss inland is going to be very large. The smokeless agencies are making efforts to place their coal on the $5.14 per gross ton basis at Hampton Roads, but even at $2 freight to Boston the proposition is not favorable enough to induce much buying. A share of what business was to be had was closed on the basis of $2.35 per net ton f.o.b. mines for Pocahontas.

No active market on Southern coals, at least, is expected before July, although the quiet purchases now being made from time to time tend, of course, to discount any really active market the coming season. Factors who own their own steamers are certain of their seaboard trade, to an extent, but those who are not so situated will doubtless find very light picking. Certainly that is the state of things today, and the attitude of the Shipping Board in not making a further reduction of rates on steamers belonging to the Government is not calculated to help.

A feature of the marine freight market is the recent reduction of rates on bituminous in railroad-owned barges. From Port Reading, N. J., to Boston the rate has been reduced from $2.05 to $1.30, the rate to points east of Newburyport being fixed at $2. This reduction is not expected to have any marked effect upon the situation, the reduction to points east of Newburyport amounting to only 40c. It will not, however, dispose the railroads in Maine to turn any more readily to steamers from Baltimore or Hampton Roads.

Bituminous prices at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net ton as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.80@3.35
Philadelphia, gross tons	4.20@4.90	5.00@5.40
New York, gross tons	4.50@5.25	5.35@5.80
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.65

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.69@5.14 f.o.b. Norfolk and Newport News, Va., for spot coal. Alongside Boston the present gross ton range would be $7.15@8.10.

Anthracite—The important announcement this week was the revision downward of rates on hard coal in barges under the jurisdiction of the Railroad Administration. Just at a time when the trade was beginning to despair of an equitable decision the new freights were given out. The $1.80 rate to Boston was reduced to $1.25, and to other points in proportion. The rate of $1.75 to Long Island Sound ports is scaled down to $1.15, and the rates to ports east of Newburyport from $2.10 to $1.35@1.50. The effect upon many retailers along the coast was almost immediate. They began filing their orders for spring shipment, realizing that the present basis is in all probability the lowest cost price of the year.

Steam sizes, and particularly dock screenings, are in short supply at all the loading piers. There seems to be a liberal inquiry for these coals, but buyers are discriminating and do not make purchases unless they can get the quality desired.

NEW YORK

Retail dealers are receiving all-rail coal in large quantities. With the mines working but little more than half time, stocks of the steam coals are kept down and prices are maintained. Consumers expected to place orders for next winter's supply. Bituminous operators watching controversy with Railroad Administration. Loaded barges scarce and good prices are obtained for them. High grade coals in demand.

Anthracite—The continuation of the marine tie-up in this harbor has resulted in more all-rail coal coming into Manhattan and the Bronx than has been received here in many years. In this way the problem of keeping the inhabitants of these two boroughs from freezing, if such a thing were necessary, has been solved, and its value may be proved in the event of a tie-up or any serious transportation difficulty at some future time. The loaded cars are brought into the city via the Poughkeepsie Bridge route and the New York Central lines and are easily transferred across the Harlem River and canal by railroad lighters. Those dealers whose yards are not located along the tracks can load the coal into trucks and cart it to the consumers.

There has not been much activity in spring buying. While retail dealers have placed orders with the wholesale dealers, the receipt of orders by them has not been up to expectations. A decided improvement is looked for during the next few weeks when consumers are satisfied that there will not be any spring decrease in prices. Dealers are circularizing their trade and advising them to place their orders early.

Retail prices in Manhattan and Brooklyn show a difference of 50c. per ton for the domestic coals, the schedule being as follows:

	Manhattan	Brooklyn
Broken or egg	$10.00	$10.50
Stove	10.25	10.75
Chestnut	10.35	10.75
Pea	8.50	9.00
Buckwheat	6.90	7.00
Rice	6.40	6.50
Barley	5.95	6.00
Soft coal	7.25	7.25

For the first time in a couple of years city departments are advertising for coal and buying it according to specifications. Since shortly after this country entered the war the specifications have been suspended and the buying was done in the open market.

Dumpings of anthracite here for the week ended Apr. 4 show an increase of more than 1000 cars over the previous week, 1917 cars having been dumped as compared with 986 the week before. During March 6439 cars were dumped as compared with 15,137 cars in February and 23,756 cars in January.

The steam sizes, because of the slow work at the mines, are not in over-supply and prices are being held firm.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	5.85	7.70
Stove	6.10	7.95
Chestnut	6.20	8.05
Pea	4.80	6.55
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The local trade has had much to engage its attention this week. Most dealers are watching the developments in the controversy with the Railroad Administration regarding coal purchases and no doubt would like to see it ended. They are also interested in the outcome of the marine strike and daily expect a settlement. Many consumers are almost without coal and are on the anxious seat regarding future supplies.

Loaded barges which were obtainable are now nearly all taken. Following the settlement with the tidewater boatmen last week there was a rush to fill the waiting boats, and many shippers were successful. Some of the barges were on their way to destination when the tugmen were ordered to stop work, and further shipments were stopped. Altogether it was estimated there were 100 barges tied up at the various terminals.

There were dumped at the local docks during the week ended Apr. 4, 3449 cars as compared with 3012 cars the week previous, and during the month of March 11,516 cars as compared with 23,668 cars in February and 23,769 cars in January.

There is a good demand for high-grade

coals, and while the range of prices does not show any change from those of a week back, there were some slight changes in individual sales on certain coals.

Buyers continue to cling to the notion that prices are going downward and hesitate before closing up for a year's supply.

Current quotations at the mine for various grades of bituminous coal for spot delivery and contract follow:

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.80 to 3.10	2.95 to 3.25
Clearfield County (good grades)	2.65 to 2.95	2.80 to 2.95
Reynoldsville	2.65 to 2.85	2.85 to 2.95
Quemahoning	2.85 to 3.10	2.95 to 3.10
Somerset County (best grades)	2.75 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.40 to 2.75	2.75 to 2.95
Western Maryland	2.50 to 2.75	2.65 to 2.85
Fairmont	2.10 to 2.35	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.35 to 2.40	2.35 to 2.60
Westmoreland ¾-in.	2.60 to 2.75	2.65 to 2.75
Westmoreland run-of-mine	2.40 to 2.65	2.40 to 2.65

BALTIMORE

A little better line of inquiry developing in soft coal and prices on immediate sales somewhat stronger. Contract quotations firm and closings few. Hard coal retail schedule is announced for a month.

Bituminous—The larger factors in the soft-coal trade here all say that there is a better inquiry for fuel. Letters are now coming in asking for quotations both on contract and on immediate sales. On immediate sales there is a tendency to stiffen now that the mine production curtailment has about reached the proportion of the demand for coal for quick delivery.

Few contracts are being made for the time being, the consumers apparently standing by the plan to purchase in the open market. The idea that the Government talk of lower coal prices is to be a real element for the future is being encouraged by consumers and laughed at by the better posted coal men. The latter say that the Government's well known attitude of discouraging any attempt to cut mine wage scales in order to allow production at a price that would enable a cut in coal prices and at the same time assure fair profits to the trade is too assured to make any material cut possible.

Locally one part of the trade, that interested in bunker coal, is not satisfied with the railroad administration rule at this point which is forcing all except coal cargo taking ships to bunker from lighters. They say that the added cost of the lighter plan is sending ships for bunker coal to Newport News, where it is possible to take bunker coal direct from the chutes. This end of the trade is also looking to the early clean-up of some 18,500 tons of navy coal stored here, which was bought by the Shipping Board to be sold to vessels under its control, to the exclusion of just that much private business in the trade.

Anthracite—The hard-coal dealers have announced their retail schedule, which is to remain in force until further notice. The prices are 40c. below those set last Nov. 11 by the Maryland Fuel Administration and which remained in effect until the present new rate was given out the past week. Dealers are now urging consumers to take coal at once, and warning that the wholesale advance of 10c. per month from May 1 will ultimately force up the retail rates. Just how and when the 50c. wholesale advance to Sept. 1 is to be absorbed by the retail trade has not as yet been decided upon. The new retail schedule, based on the long ton of 2240 lb., with 25c. off for cash within ten days of delivery and 50c. a ton added for all bag or wheelbarrow haulage from carts to cellars, is as follows:

	Ton	Half Ton
Hard White Ash—		
No. 1 (broken)	$11.50	$5.90
No. 2 (egg)	11.50	5.90
No. 3 (stove)	11.75	6.00
No. 4 (chestnut)	11.85	6.10
Pea coal	10.00	5.15
Buckwheat	8.20	4.25
Sunbury—		
No. 2 (egg)	11.50	5.90
No. 3 (stove)	11.75	6.00
No. 4 (chestnut)	11.85	6.10
Lykens Valley—		
No. 2 (egg)	12.20	6.25
No. 3 (stove)	12.60	6.45
No. 4 (chestnut)	12.60	6.45

PHILADELPHIA

Anthracite trade improved by cold spell. Dealers clean up old stock. Better April outlook. Retailers discuss credits. Criticism of freight rates. Stove and nut in demand, egg fair, with pea lagging. Buckwheat moving well, rice also. Barley very heavy. Bituminous shows little improvement. Shippers ask fair rail fuel price. Interest in exports.

Anthracite—Due to the unusual change in weather conditions business at present is enjoying quite a spurt. Cold weather as severe as any during the past winter, together with high winds, caused many householders to hurry to their coal man. The demand for immediate deliveries in small lots was too great to be taken care of to the satisfaction of the buyers, and many homes were cold for a day or two. It has been a long while since the dealers were flooded with so many orders for half tons.

Most representative dealers seem inclined to carry capacity stocks, but they point out that the present high prices, together with the heavy freight rates, makes the investment in a big stock too much to carry without considerable cash business. With this end in view several of the larger dealers have been advocating, and some have actually agreed to advance the present prices 25c. a ton, with a discount of the same amount if bills are paid within five days. Another plan was to continue the present prices and offer a discount of 25c. therefrom as an inducement to pay cash.

There is considerable dissatisfaction among the shippers as well as the dealers over the freight rates. The dealers located on the Pennsylvania R. R. tracks are protesting because under the regular tariff they are compelled to pay 10c. per ton higher rate than their competitors on the Reading Ry. Some shippers cannot compete for business on the Reading Ry. because of prohibitive rates. In some cases it amounts to an additional 20c. per ton, and their trade say they cannot afford to pay the difference. In no cases have we learned of the shippers absorbing the excess.

The demand for stove and nut exceeds that for the other sizes, and all shippers have a comfortable supply of orders for them. Egg is quite fair, while pea coal still lags. Several shippers report having changed their screens and to be shipping a larger size pea, but the dealers claim there is still room for improvement. It will probably be some time before this former most popular size recovers from the setback caused by the lowering of the standard of preparation and increase in price.

While the demand for buckwheat is light, yet the production is reported to be well absorbed on account of the former light working time; but with increased operating days it is believed that there will soon be more than enough to go around. Contracting is very slow, and while shipments to the large buyers continue, the signed contracts for some of them have not been returned to their shippers. The price for transient business is being cut by some of the individuals, but not to the extent of several weeks ago. We hear of sales around $3. Rice is in somewhat better demand than buckwheat at this time, but can still be bought for close to $2.25. Barley is away off and most shippers are having trouble with it. Sales are reported as low as $1.50.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5 95	$7.80	Buckwheat	$3 40	$4 45
Egg	5.85	7 70	Rice	2.75	3 65
Stove	6.10	7.95	Boiler	2.50	3 50
Nut	6.20	8.05	Barley	2.25	3.15
Pea	4 80	6.40			

Bituminous—The trade continues quiet. Whether there is any improvement over the previous period is hard to determine. Some shippers admit conditions to be better, while others are inclined to believe the reverse. Certainly there is little activity. Contracting continues to be uppermost in the minds of most shippers, and with some new business closed occasionally as the manufacturers begin to realize that there is little chance of better figures being offered.

We give below a list of prices prevailing in this market, although it is difficult to compile them with accuracy, for while the table represents prices the operators feel they should have, we believe that they are being shaded in quite a few instances:

Georges Creek Big Vein	$3.00 @ $3.10
South Fork Miller Vein	2.90 @ 3.10

Lake Markets

PITTSBURGH

Market but little changed. Steel industry consuming less coal. Lake shipments will largely be deferred.

The controversy regarding prices the railroads will pay for coal has not had any great influence upon the local coal market, for the reason that transactions had been of a hand-to-mouth character. Of more importance to the local market is the fact that the reduced prices for steel, as developed by the Industrial Board and effective in the open market Mar. 21, have not resulted in increased buying. Some orders for steel that would have been placed at the old prices if there had been no prospect of reductions were held back and have since been placed, but no new buyers have appeared.

The investment buyer was not brought out by the steel reductions, and so the Director General of Railroads, in refusing to buy at the Industrial Board prices, is merely keeping company with the public. Steel mill operations have decreased further and the outlook for coal consumption in the steel industry is far from good. The tinplate mills, which consume a particularly large amount of coal per ton of output, are not running as well as it was expected they would be by this time.

Domestic coal trade is poor, the season being practically over. A little lake coal is being moved, but not much, and it seems probable that nearly all the season's movement will occur in the second half of the navigation period.

There is more cutting on steam coal, $2 being frequently accepted. Quotations of a week ago are repeated except for mine-run steam coal: Steam coal—Slack, $2@2.10; mine-run, $2.10@2.35; Gas—Slack, $2.25@2.35; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.75, per net ton at mine, Pittsburgh district.

BUFFALO

Some report of improvements. Others are calling the situation unfavorable. An increase of bullish reports ought to mean something. Anthracite going afloat fast. Retailing moderately active.

Bituminous—"I am decidedly optimistic," said a Buffalo jobber. He sells about as much coal as anyone and ought to know the market. At the same time there is not much improvement in sight. However, it looks as if the turn in the trade was not far away, so the shippers are hopeful. The despondent coal jobber is not so numerous as he was.

The Canadian market does not improve, for manufacturing there is not so good as it was, and it does not appear to be increasing. Jobbers are still covering that territory as carefully as they can, but the salesman who can sell much coal is a genius. This condition is likely to last some time yet.

Bituminous prices are pretty firm. Some bidding on contracts has been low, but it is asserted by the trade generally that the coal offered was not up to standard. Jobbers quote, as before, $2.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh and No. 8 lump; $4.20 for same, mine-run and slack; $5.65 for smithing and smokeless, and $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The trade is better than usual, considering that many consumers laid in so much coal. We have just passed a week of the steadiest cold weather of the season, the capriciousness of it being shown by the fact that on the night of Mar. 26 we broke the high temperature record—70 deg.—and on the night of Apr. 1, six days later, we broke the low record—11 deg.

The real activity in anthracite is in the loading of lake vessels, about 35 now having received cargoes, totalling a matter of 200,000 tons altogether. The other side of this is that nobody wants the coal, and the vessels are waiting for something to bring back before they sail. In spite of the open water the opening of the season promises to be late.

Local anthracite prices range as follows:

	F.o.b. Cars, Gross Ton	At Curb, Net Ton
Grate	$8.55	$10.35
Egg	8.45	10.20
Stove	8.70	10.10
Chestnut	8.80	10.50
Pea	7.00	9.05
Buckwheat	5.70	7.75

With 25c. additional for loading to lake vessels.

CLEVELAND

Contracting in the first week of the new coal year, which has opened quite briskly, has developed decided weakness in bituminous coal. A good-sized block of No. 8 ¾-in. lump for the head of the lakes has gone at $2.35, a reduction of about 25c. over last season. Offers of No. 8 ¾-in. lump to northern Ohio users have ranged all the way from $2.60 to $2.20. Weakness is in evidence all along the line, and the general appearance is that the market will grow softer before it again grows stronger.

Bituminous—After having held for weeks to their claim that they could not afford to shade former Government maximums, and permitting operations at their mines to drop to 20 and 30 per cent. in substantiation of this claim, operators in the No. 8 district of Ohio have weakened. Any amount of standard No. 8 ¾-in. lump can be contracted for now at as low as $2.20, and an inquiry for a tonnage of alluring size doubtless would shave another 10 or 15c. off this figure.

One big No. 8 operator has opened the new coal year by selling 200,000 tons of No. 8 ¾-in. lump to an upper lake dock interest for $2.35. Not only is this a reduction of 25c. over one year ago, but the commission and handling charges were lowered proportionately. Last week the 1918 lake carrying charge of 48c. a ton was abandoned and the 42½c. rate of 1917 revived.

A fair-sized contract for No. 8 district prepared sizes is reported made at $2.50. The last Government price on this grade was $2.60. Several good-sized sales of No. 8 ¾-in. lump to northern Ohio users at $2.35 also are reported.

Efforts still are being made by operators to persuade steam-coal users to stock now in anticipation of a shortage of both coal and cars Nov. 1 or shortly thereafter. The only ray of hope for the domestic trade is the threat of the natural gas company supplying Cleveland to double its price in order to force domestic consumers to abandon gas in favor of coal for heating purposes next winter.

Lake Trade—Bituminous cargoes are in greater demand for lake shipment than last week, and the trade is picking up a great deal faster than even the most optimistic had hoped for. The first cargo probably will not be unloaded at an upper lake dock much before the first of May. With the 1919 carrying charges fixed—42½c. a ton to the head of the lakes and 50c. to Lake Michigan—and the first authenticated sale of lake coal announced, every obstacle to a free movement in the lake trade has been eliminated.

Prices of coal, per net ton delivered in Cleveland, are:

Anthracite:	
Egg	$10 85 @ 10 95
Chestnut	11 00 @ 11 10
Grate	10.90 @ 11.05
Stove	11.05
Pocahontas:	
Lump	7 50
Mine-run	7 20
Domestic Bituminous:	
West Virginia splint	7.05 @ 7 15
No. 8 Pittsburgh	6.15 @ 6 35
Massillon lump	6.95 @ 7 10
Steam coal:	
No. 6 slack	4 45 @ 4 55
No. 8 slack	4 75 @ 4 90
Youghiogheny	4 95 @ 5 05
No. 6 mine-run	4 45 @ 4 55
No. 8 mine-run	4.85 @ 5 10
No. 8, ¾-in	5.40 @ 5 60

DETROIT

Lack of demand, owing to large reserves on hand, is a feature of the unsatisfactory conditions in the Detroit market for bituminous coal.

Bituminous—With only a small volume of buying, jobbers and wholesalers say the Detroit market could scarcely be more unsatisfactory than they now find it. Orders come irregularly and in a scattering way, and are seldom for quantities greater than one or two cars at a time, suggesting a sort of hand-to-mouth effort on the part of buyers to fill in for current requirements. Retail dealers are taking domestic lump in small consignments, stipulating speedy delivery, with a view to getting the coal to their customers before higher temperatures arrive.

While lump and prepared sizes are usually holding at the fuel administration prices, slack and mine-run find buyers less readily and with only a small amount reaching Detroit; quotations are said to have been made on slack as low as $1.65 at the mines, with similar shading of price on mine run. Jobbers say that Government prices are the basis of quotations on prospective contracts, though little interest is noted in that direction.

Anthracite—With receipts of anthracite only moderate in amount, the market is apparently well supplied. Numerous retailers are urging domestic consumers to stock up now for next winter and are announcing their ability to fill orders for any size to the full extent of the customer's requirements.

COLUMBUS

The oversupply of small sizes is one of the big features of the coal trade in Ohio. Operators are at a loss to dispose of the slack and consequently are curtailing their production of lump. Contracting is still slow.

Operators and shippers are finding it difficult to dispose of their screenings. Because of lack of demand for the small sizes screenings have become a drag on the market and as a result the production of prepared sizes is being reduced. There appears to be no remedy for this situation, and operators see little indication of an increase in demand for slack.

General steam business is still rather slow, as contracting is being held up by the unsettled price situation. Quite a few contracts expired around Apr. 1, but few have been renewed. Because of the large amount of spot coal available, much of it at reduced quotations, consumers are slow in entering into contracts.

Sales agents are now devoting their time to calling on the trade and getting an expression as to when the purchaser will be in the market. Some contracts have been made with the price left blank, to be filled in when settled quotations are developed. Some lake contracts have been made in the same way. But generally speaking, the consumer is playing a waiting game and is not disposed to rush matters.

Domestic business is rather quiet. Retailers are not buying to any extent. Some demand for the fancy grades is reported, and there is quite an inquiry for Pocahontas and West Virginia splints. Retail stocks are fairly large, and consequently dealers are slow to buy. There will be a considerable tonnage carried over by consumers. Retail prices are being cut to a small extent, but the larger yards are still maintaining quotations.

LOUISVILLE

Demand slightly better for steam coal, but large operators figuring on a dull market for 30 to 60 days. Lake movement slow in starting. Prices fairly well maintained.

There has been a slight improvement in the demand for steam coal during the past few days, but domestic is rather draggy, and more effort is being made to sell straight mine-run than any other grade, as it enables the operator to produce coal more profitably, considering the weakening demand for domestic. Some of the small mines not equipped for screening have been offering mine-run at considerably under the market, resulting in close competition.

Prices as a whole are about the same as they have been, although many operators are quoting no domestic for less than $3 in eastern Kentucky, and the Jellico district has set a price of $3.25 for domestic during the months of April, May and June. Some little spot coal is reported to be selling at low prices, but jobbers say that when they go to buy such coal they find that it has been taken up, or that the reports were not correct. However, a few operators on the Louisville & Nashville lines are known to have quoted at low as $1.90 per ton on mine-run direct to large industrial consumers for immediate shipment. Some of this coal is under grade.

A few of the leading operators foresee dull business during the rest of April, and probably well into May, due to the fact that immediate delivery business is not heavy, and neither the operator nor the buyer can get together on contract prices. The mine operator is not anxious to contract at even the so-called Government figures, and the industrial consumer wants an even lower price.

Demand for steam coal is picking up somewhat, due to the fact that some industries are running low, and others are opening up for the spring season. Brick plants are just getting started and report a fair volume of business, considering the generally dull building movement.

Quotations on a short-ton basis for eastern and western Kentucky fields are as follows:

	Eastern Kentucky	Western Kentucky
Block and egg	$2 85@$3 00	$2 60
Run-of-mine	2 25@ 2 40	2 35
Nut and slack	2 00@ 2 10	2 05

Brokers are allowed 15c. per ton on these prices.

BIRMINGHAM

Steam demand continues light. High-grade domestic sizes readily taken, the supply not being equal to requirements of the trade. Some improvement shown in sales of cheaper grades. Production slightly heavier than previous week.

Buying of steam fuel continues to lag and trade conditions have not improved over the previous week. Consumers who have exhausted their stocks are only taking such tonnage as will supply their needs of the immediate future. The Frisco R. R. closed contracts for approximately 20,000 net tons per month with mines on its lines in Walker County, to extend over a period of twelve months from Apr. 1. The agreements embodied a clause allowing the cancellation of such contracts at the option of the railroad upon 30 days' notice in the event the lines were returned to private ownership, Government prices being paid for the fuel.

High-grade domestic coal is reported to be exceedingly scarce and the demand good. Contracts for this grade of fuel are being readily signed, and some improvement is also noted in the demand for cheaper coals. Several days of wintry weather boosted the retail market to some extent. Quotations remain steady as follows per net ton mines:

	Lump and Nut
Montevallo	$5.00
Cahaba and Black Creek	3.85
Carbon Hill	3.15
Big Seam	2.90

Coal production for the week ending Mar. 22, as reported to the Alabama Coal Operators' Association, totaled 289,071 net tons, a small increase over the week previous.

Coke

CONNELLSVILLE

Spot furnace coke easier. April adjustments not completed. Production continues to decline.

Instead of the meeting of coke operators at Uniontown stiffening the market situation, prompt furnace coke has been offered at lower prices than formerly. The Uniontown meeting developed a general opinion that furnace coke should bring $4.50 and that when that price could not be secured production should be restricted. Furnace coke of excellent grade has since sold at $3.75 in spot lots, and while the price has not been done on a month's supply, it is thought in some quarters it could be done.

Operators having adjustments for April shipments to make under contracts started out by asking $4.50, but this proved quite unacceptable to furnaces, and operators will do well if they settle at $4.25, the price that obtained in most of the March adjustments. Contracts that were written at "last Government price" are running at $6 in one or two instances, others remaining at the $5 price the operators conceded some time ago. Operators holding such contracts would probably be glad to make concessions if the furnace interests would undertake to run fuller and thus take more coke, but the furnaces are not in position to do this, finding it practically impossible to sell pig iron and depending entirely on their contracts, deliveries against which are slowing down.

Foundry coke is in only fair demand, and some operators who were asking the higher prices have reduced quotations; but the lower grades are unchanged. The market is now quotable as follows for spot and prompt shipment: Furnace, $3.75@4; foundry, $4.50@6, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Mar. 29 at 185,660 tons, a decrease of 2140 tons.

Buffalo—The trade is quiet and shows no improvement. As a rule the furnaces have a large supply of iron ore on hand and are in no hurry to bring down more, so it is quiet all along the line. The prospect is for some weeks of quiet, and then the trade will proceed with at least the normal activity. Coke is obtained mainly at the byproduct ovens here at prices that correspond with the prices of the Connellsville district, which are $7 for 72-hour foundry, $6 for 48-hour furnace and $4.50 to $5 for the lower grades, all f.o.b. Buffalo.

Middle Western

GENERAL REVIEW

Uncertainty characterizes attitude of buyer and seller alike. Railroad officials predict car shortage in near future. Feeling that dull period is past.

The coal market in the Middle West is more interesting today than it has been for some time. There is a feeling of uncertainty throughout the industry itself, as well as through the consuming public. Purchasing agents have not yet made up their minds whether they want to make a contract or whether they want to purchase coal on the open market. One week the purchasing agent is in favor of the open market plan, and the next week he favors a contract at all costs. The operator, although he is on the opposite side of the fence, has the same mingled feelings. In a great many instances the producer is not anxious to make a contract at present prevailing prices, because he feels that the labor situation is such that coal will be hard to get in some fields within 30 to 90 days, and he wants to have a lot of free coal, in order to take advantage of any such situation, should it arise. On the other hand, a contract looks pretty good to him, because it will allow him a small margin of profit, and he will be able to give his mines a steadier running time. It is noticeable that many more contracts have been reported this week than any previous week so far this season.

Railroad officials in North Dakota, South Dakota, Iowa, Wisconsin and Minnesota are predicting a great car shortage along about next July to October. The grounds for this prediction are that from all figures obtainable, our grain crop will be tremendous: in fact, very much greater than ever before. This, of course, is brought about by the Government's protection of wheat. This expected crop of wheat will have to be moved, and box-cars will be used. As a result there will be a tremendous shortage of box-cars, and the Northwest will have to depend on open equipment for its coal, something heretofore unknown.

A rather curious situation has arisen in the retail trade. The retailer does not take very favorably to the increased cost of anthracite coal, however just this increase may be. As a consequence, the retailers are predicting that less anthracite will move into the Middle West than ever before, and that this hard coal will be replaced by coke and by the better grade bituminous fuel from southeastern Kentucky and West Virginia. This situation is already beginning to be felt, as those operators producing very good coals from the eastern bituminous fields are reporting excellent market conditions, while we understand that but little anthracite is moving into the territory.

CHICAGO

Steam trade still dull. Prices being cut on eastern coals. Eastern Kentucky mine-run has obtained hold on local market.

The steam trade in Chicago continues dull, although a little more coal is moving than moved last week. The Chicago purchasing agents, however, do not seem to look with favor upon contracts, and we believe that the majority of them are planning to purchase their fuel on the open market. It will be interesting to see what the future has in store for these gentlemen.

The domestic trade is curious. West Virginia is anxious to get back its old standing in the Chicago retail market. There are many sales agencies in this city handling West Virginia coal, and as a result competition has been keen, rather than healthy. As a natural result, prices have been cut, and those dealers wishing Pocahontas, or other high-grade eastern coals, are able to buy them considerably under the market. The southeastern Kentucky operators, however, have not entered into this price-cutting orgy, as they are maintaining their prices in the face of the slices made by the West Virginia people. Some of the better grade eastern Kentucky coals have won a place in the Chicago market which cannot be taken from them.

We understand that a number of plants formerly using Pocahontas coal are now using eastern Kentucky mine-run. The demand for Franklin County, Clinton fourth vein coal, and other high-grade products produced in the Middle West, appears to be good, although there could be an improvement. The public—that is, the householder—is doing some buying, as he has just about come to the end of his winter supply of coal, and will need a few more tons to keep going until the summer sets in.

Prices per ton are as follows:

ILLINOIS

Southern Illinois Franklin, Saline and Williamson Counties, etc.	F.o.b. Mines	Rate to Chicago

MILWAUKEE

Warm weather and a glutted market fail to affect the price of coal. Slow buying continues. Coke piling up.

The coal market continues lifeless. There is a great surplus of supplies for the season, which continues warm. Private consumers and industries are simply buying enough to cover immediate needs. The problem of sustaining prices has been an easy one thus far, as there has been no disturbing competitive influence from the outside. A shading in soft coal is expected when Western operators get busy in the interior for the new season. Coke stocks are piling up at the byproduct plants, but prices are being maintained.

ST. LOUIS

Easy weather conditions and nothing to stimulate market. Everything is quiet, with domestic demand off to the extent that steam coal is beginning to strengthen. Outside coals plentiful with no demand.

The local situation continues easy. The weather has eliminated nearly altogether the demand for domestic coals. A week or two ago steam sizes were extremely heavy and the mines were idle on account of their inability to move them. The condition has changed now, and screenings are somewhat scarce. This, of course, is occasioned by reason of the fact that there is no demand for lump coal for domestic purposes, and with the falling off in this tonnage there is a decreased amount of screenings offered. There is no unusual demand for screenings, but it is the ordinary call at this time, which is commencing to catch up with the supply. This has a tendency to strengthen the steam market. On the other hand, nut is the slowest size right now. Egg size follows this, and the 2-in. lump is moving more freely than anything else on account of the usual call for this as the steam fuel.

Several of the mines have been down entirely on account of the dropping off of business and others are working one and two days a week. The railroad tonnage dropped off suddenly on the first, except temporary orders and temporary contracts.

Conditions are in a deplorable state throughout the Standard field, but with the operating companies getting at least cost for their output there is always room for improvement. The railroads are not taking up contracts as fast as was expected.

In the Mt. Olive field conditions continue in the same quiet, usual way characteristic of that section. The domestic tonnage is extremely light and there is nothing heavy in the way of steam. The mines are getting a couple of days a week and the coal is moving north.

In the Carterville field in Williamson and Franklin Counties, as well as the DuQuoin field of Perry County, lack of business is beginning to be felt more keenly by the larger operators, and a substantial supply of unbilled coal is usually on hand overnight. This has been mainly steam fuel, the demand for which, however, is beginning to catch up to the supply. A number of mines in this field are idle because many of the railroad contracts which expired on Apr. 1 have not been renewed.

The Missouri Pacific contract, with a maximum of 3000 tons daily, went to the West Virginia Coal Co. with mines in Williamson County, at a price, it is rumored, of $2.07½ per ton f.o.b. mines for mine-run. Other contracts have not been made public as yet, but the majority of the contracts in this field have not been closed. The open market price on some of this tonnage at the present time is $2.

The market is quiet and easy, and there is nothing to indicate that business will improve until some time in May.

In St. Louis proper everything is slow. Little anthracite is moving in, although the demand for country business is picking up some on chestnut size. Smokeless coal is plentiful, with no orders, and the demand for domestic coke is unusually light.

The prevailing circular at the present time f.o.b. the mines is:

Williamson and Franklin County Association:		Mt. Olive and Staunton		Standard	
Lump, egg and nut	$2.75	....		....	
Washed Nos 1 and 2 nut	2.85	....		....	
Independent:					
Lump, egg and nut	2.55	2.55	Lump and egg	2.25	
Washed Nos. 1 and 2 nut	2.85	....	2x3 nut	2.00	
Mine-run	2.35	2.20		2.00	
Screenings	2.20	2.05		1.75	
3-in. lump	....	2.30		....	
2-in. lump	....	....		2.15	
2x6 egg	....	....		2.10	

Williamson-Franklin rate to St. Louis is $1.07½; other rates $0.92½.

Some Further Thoughts on Labor

By Floyd W. Parsons

IF anyone has ever believed in the unqualified control of business by the state, the case of the railroads in this country should at least bring a doubt to his mind. Our recent experience has caused many to decide that when politics comes in at the door economics goes out through the window.

In 1914 the average annual wages of the railroad employee was $810. This year the average annual earnings of each employee will be at least $1460. In the past three years nearly $1,400,000,000 have been added to railroad wages, and in less than ten years the average increase has been upward of 120 per cent.

Although the Government has increased fares and rates more than a billion dollars, it has been unable to catch up with the wage increase. Rates must be raised at least another 20 per cent. if the railroad deficit is to be wiped out. In view of this wage situation it is no wonder that the holders of railroad securities are in no hurry to have the transportation lines turned back to private control.

The high prices for necessities are clearly due to the high wages paid to those who produce and distribute the things we use and consume. It is therefore vital that industry shall be again placed on a sound economic basis, and that the Nation's business shall not be used by any party as a pawn to curry political favor.

Notwithstanding the fact that American conditions differ considerably from those prevailing in Europe, our industrial history has shown that business in the United States has generally followed along the same paths trod by our cousins in Great Britain. Many American employers still hold views that were current in England four or five years ago. The British now recognize generally the desirability of capital and labor bargaining collectively. In fact the English employer is decidedly in favor of the national union as opposed to a purely local works committee. Where shop committees do exist, the owners desire that such bodies come under the discipline of their unions. It is commonly recognized that this contributes to the stability of industry.

As for British employees, they are unanimous in their opposition to the use of force in attaining their aims. Almost none approves of a sudden change, as in Russia. The radicals among the workmen oppose collective bargaining on the ground that it fosters harmony, which they claim helps to continue the present system of society. But the majority of British workmen are of the conservative type, and although they are earnest in their desire to strengthen their unions, they are in accord with the employers in believing that it is best for the Nation if there is no restriction on output except as it affects the health of the employee. Most workmen also wish to leave control of business policies in the hands of those managing the business.

All of which leads to the conclusion that although we are entering a new era in industry, the leading nations are confronted by no problems that cannot be sagely met. Government ownership has been tried and valuable lessons have been learned. The loyalty and patriotism of workmen have been tested and sanity prevails among the great majority. Cooperation and conciliation are the national watchwords. Farseeing employers are not attempting to bring back pre-war conditions, and right-minded employees are commencing to recognize the danger to business from crowding labor's demands.

Let us, therefore, discard our blue glasses and see affairs in the full light of a new day.

IDEAS AND SUGGESTIONS

Responsibility of Labor

By N. H. Seaburg
Boston, Mass.

Employers have always chafed under the industrial arrangement whereby labor is given power without responsibility. It has been their most grievous complaint against and objection to collective bargaining, because even the state must bend to the wishes of labor—be those wishes right or wrong—if it but exerts its full power. Several concrete illustrations in support of this latter statement have been afforded during the past two years, and employers are more confirmed than ever in their conviction that there is no court of appeal to which they may carry their cases against labor. Labor, they argue, has placed itself above the state.

During the troublesome times just past, employers were unanimous in their oft-repeated assertion that "Labor can get anything it wants in Washington these days." More recent developments have not caused them to change that opinion, and consequently employers are sorely depressed by the outlook. In the coal industry, with its great labor problem, the extent to which labor has Washington under its thumb may be put to the test should there be a general strike. A strike, however, at this time would be no serious calamity to the operator. On the contrary, it would relieve him of much anxiety, principally that of trying to keep his men working a few days a week, if possible, under the present discouraging conditions. The great danger of a clash today lies in the potential effect it may have upon the future industrial peace of the operator and miner. On both sides seeds of bitterness may be sown that may ripen into disaster sooner or later.

Like war, strikes are destructive and in that sense are wasteful to an industry. It is a shortsighted policy to dam up at considerable expense the small loopholes of waste in business and leave the front door wide open for its entrance. Labor is the front door in the coal business, and to keep it safely and securely closed today the operators must take cognizance of the change which labor has undergone.

Perhaps the most confusing demand that the miners may make of the operator today is their desire as growing human beings to have a voice in the management. Throughout the labor world this ambition has long been smoldering, but it has never before now crystallized into an actual demand. The English employer is face to face with it, as, of course, is also disrupted Russia. It is a desire international in demand. Superficial consideration of this new problem may possibly arouse the fighting instinct in many employers, but when subjected to the calm test of reason it will not seem so destructive in character.

Employers, as remarked before, have always bemoaned labor's power without responsibility. Instead of trying to break that power, as some employers have done and are doing, the best way to remedy it is to increase labor's responsibility. Responsibility is a stern policeman, and is far more effective than mere authority. Possibly, therefore, in this new ambition of the workers for a place in the management the employer may find his salvation, as it will mean sharing his responsibilities with his workers.

This course would be of particular advantage in a period like the present, when the miners, through their councils or committees, would be kept fully informed of the depressed status of the market. Knowing the truth about conditions, they would be apt to mark time as best they could, realizing that the operators were not any more responsible than they themselves. So, too, they could be educated and kept informed on all other phases of the industry which might affect their work from time to time.

It is true that operators could carry on this task of enlightenment just as well without a miners' council or committee, but it would not have the confidence of the workers. The latter cannot, on the other hand, doubt the information their own representatives would furnish them. Thus, by an intelligent understanding of their industry the workers would be in a better position to judge of the reasonableness and justice of the demands they might make upon their employer. Local disputes and questions of every kind could also be settled by these councils without recourse to a national upheaval.

The old belief that neither side can gain except at the expense of the other should be relegated to the dumping grounds for myths. While they have many interests that are entirely different, yet they have so much in common that coöperation and not conflict should be the basis of their relations. And if this is so, why should labor not bear its share of the responsibilities? Labor's power would then also be the employer's power, their interests being mutual.

Various Timbering Methods

By M. M. Haley
Sturgis, Ky.

In the "Ideas and Suggestions" department of *Coal Age*, Feb. 20, appeared an excellent article on mine timbering by Joseph R. Thomas, of Plymouth, Penn. Some time ago I had made what might be termed a suggestion sheet on methods of timbering. This sheet I had blueprinted and distributed to all timbermen and others interested in or charged with the upkeep of the mines. Such drawings are always welcome to those who are ambitious and anxious to improve mining conditions or the quality of their own workmanship.

No hard or fast rules can be applied to any or every set of conditions, and the experience and good judgment of the timberman must always be relied on if the best results are to be obtained. The sheet shown on the facing page therefore contains suggestions, but not rules or instructions, for almost any contingency likely to be encountered in timbering in actual mining practice. The idea is merely an adaptation to the mine of methods in everyday use in shops and factories.

This Suggestion Sheet on Methods of Timbering Brought Increased Effectiveness on the Part of the Men

Fusibility of Ash from Coals Found in the Interior Province*

By W. A. Selvig, W. C. Ratliff and A. C. Fieldner
Fuels Chemical Laboratory, U. S. Bureau of Mines, Pittsburgh, Penn.

SYNOPSIS — *Coals from the various states in the Interior Province, with the exception of those from Iowa and Michigan, not yet tested, show a great similarity in the fusibility of their ash content. Results obtained in the laboratory may not coincide with those secured in the boiler furnace, but the method of test followed was selected as giving a close approximation to the results that might be expected in the ordinary commercial consumption of the coals tested.*

THE Interior Coal Province, which includes all of the bituminous coal fields near the Great Lakes, in the Mississippi Valley proper, and in Texas, contains a vast amount of coal which is extensively mined and has been an important factor in the development of the great manufacturing centers of this region.

While there is a large amount of analytical data available as to the composition of these coals[1] there has been no general survey of the fusibility of ash from the various coal beds comprising this great coal province.

The fusibility of the ash is of great interest to the consumer of coal, principally in connection with the formation of clinker due to the melting of the ash constituents of the coal when fired under boilers. The Bureau of Mines is therefore making fusibility tests on the well-known American coals, and this paper includes a table giving results for coal from each mine tested in the Interior Province. A previous paper[2] gave a description of the standard gas-furnace method used by the Bureau of Mines in making ash fusibility tests, together with a complete table giving results obtained for the coal from each mine tested in West Virginia.

It is well to bear in mind that fusibility tests as made in the laboratory are not directly comparable to the conditions existing when coal is burned in a furnace. In a laboratory test the impurities remaining as ash are intimately mixed. Obviously, there is no such uniform distribution when the coal is burned in the ordinary manner. Fieldner, Hall and Feild[3] have shown that in a laboratory fusibility test various factors have a great influence on the results obtained. The standard gas-furnace method as used for the tests takes into consideration the different factors influencing the results obtained, with special reference to the atmosphere surrounding the ash during the test. With this method the atmosphere in which the ash is heated is readily controlled by burning an excess of gas, under which condition a reducing atmosphere is obtained. This reduces the iron in the ash to the ferrous state and gives the lowest temperature at which clinkering may result.

This is of special importance in testing ash from coals of the Interior Province, as they contain a relatively large amount of iron in the form of pyrite. Consequently, higher softening temperatures may be expected in tests using oxidizing atmospheres by which the iron would be oxidized to ferric oxide, or in tests using strongly reducing atmospheres by which the iron would be largely reduced to the metallic state. In both of these conditions a more refractory and viscous slag is formed than would result if the atmosphere were such as to reduce the iron in the ash to the ferrous state, which gives the most fusible condition.

Analyses of clinkers from boiler furnaces indicated that the conditions were such as to form clinkers in which the iron is present principally in the ferrous state, consequently the values obtained in the laboratory tests are in this respect comparable to the actual fuel-bed conditions, and give the lowest temperatures at which the intimately mixed ash will soften with the formation of clinker.

Interpretation of Fusibility Table

The states comprising the Interior Coal Province are arranged according to the coal region in which they belong; the eastern region (Illinois, Indiana and western Kentucky); the western region (Kansas, Missouri, Oklahoma and Arkansas); and the southwestern region (Texas). Michigan and Iowa, which are included in the Interior Province, are not represented in the table as no mine samples of coals from these states were available when the tests were made. Under each state the tabulation is alphabetical according to bed, county, town and mine.

The samples represented are practically all standard mine samples collected by representatives of the Bureau of Mines, the U. S. Geological Survey, or by the various state geological surveys, according to the methods used by the Bureau of Mines.[4] A small number of car samples which were considered representative of the output of the various mines were also included.

The number of samples from each mine, the lowest, highest and average softening temperatures in deg. F.,

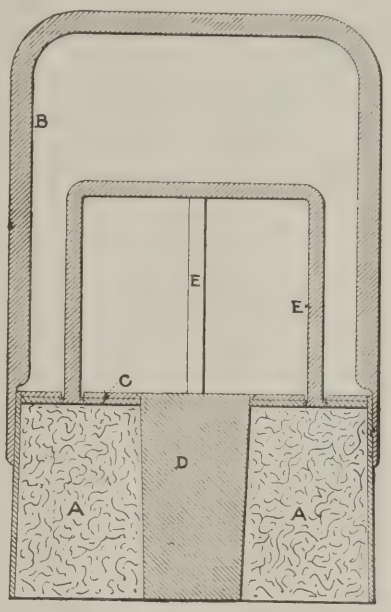
and the per cent. ash and sulphur in the dry coal are tabulated for each mine tested. Average values for each mine were computed from the individual samples, and from these values averages representing each bed were obtained. It is evident that the greater the number of mines sampled the more representative are the average values for the beds. This should be kept in mind as in some instances the average values given for the beds represent only a few mines and are then not truly representative of the coal bed.

The point taken as the softening temperature is that at which the ash, when molded into solid triangular pyramids $\frac{3}{4}$ in. high and $\frac{1}{4}$ in. wide at the side of the base, and mounted in a vertical position, has fused down to a spherical lump. Points at which the tips of the cones first fuse, and at which the ash has become very fluid, are also taken and serve mainly as an indication of the viscosity of the melting ash; however, these values are not tabulated in the table.

In general the softening temperature of coal ash from the various coal fields of the United States ranges from 1900 to 3100 deg. F. For convenience in discussion, the order of fusibility of ash may be expressed by subdividing this range of softening temperature into three groups as follows: Class 1, refractory ashes, softening above 2600 deg. F.; class 2, ashes of medium fusibility, softening between 2200 and 2600 deg. F.; class 3, easily fusible ashes, softening below 2200 deg. F.

The softening temperature of the ash from the

Interior Province coals is uniformly low. With the exception of the Santo Tomas bed in Texas and the No. 4 bed in Indiana, all the average fusibility values of the various beds are found in class 3 (1900 to 2200 deg. F.). There is no such variation among the beds as was found in the coals of West Virginia,[5] where all three classes of fusibility are well represented. It is interesting to note that the class 3 beds of West Virginia which show low softening temperatures comparable to the Interior Province coals are those in the Monongahela, Conemaugh and Allegheny series, these coals being the uppermost coals of West Virginia and geologically the youngest. Most of the class 1 and 2 coals occur in the lower and older beds of the Pittsville series.



The uniformly low softening temperature of the ash from the Interior Province coal is unquestionably due to the quite general distribution of pyrite, calcite and frequently gypsum in the coal beds of this region. The percentage of iron and lime in the ash is usually quite high. In general it might be said that individual mines producing lower sulphur coal than the average sulphur values given for the bed in which they occur also gave higher fusibility of ash than that indicated by the average value for the bed.

As may be expected, samples from the same mine will give ash varying in fusibility due to the difference in the composition of the ash-forming constituents included in the sample. This variation of fusibility of samples of coal from the same mine in the Interior Province is not large, averaging only 140 deg. F. in the mines represented in the table. Only in a few instances does the difference between the lowest and highest softening temperatures of a number of samples collected from the same mine exceed 300 deg. F. The majority of mines gave samples coming within the average difference of 140 deg. F. between the lowest and highest values.

Novel Coal Cake Developed and Used at the Western Front in France

Under the title of "Homemade Fuel," a process for the utilization of anthracite dust was described in the Sept. 5, 1918, issue of *Coal Age*. This was a wartime suggestion. In the Oct. 18, 1918, issue of the *Colliery Guardian* there is described a similar method developed and used in the actual theater of war on the Western front. Considerable interest attaches to this latter scheme as it has in view the utilization of anthracite and other coal dust; the coal cake (called the Ablain coal cake) is made in a simple mold by hand, the particulars of which were furnished by Col. R. Standen. This coal cake is composed of a mixture of coal dust and either clay or chalk, compressed into perforated cylindrical cakes, measuring about 3½ x 2 in., or 2½ x 1¾ in. For some months past these cakes have been in use by a portion of the British armies in France. The material used was obtained from adjacent coal mines and was mixed in the proportion of two-thirds coal dust to one-third binder. Satisfactory results have also been obtained with four-fifths ground Welsh steam coal and one-fifth of either of the binders mentioned. Charcoal powder has also been used, a mixture of three-fifths charcoal to two-fifths binder being employed.

The mold used in this process is illustrated in the diagram. It consists of a cast-iron shell with the rigid handle *B* and the movable ejecting plate *C*, the latter being operated by the handle *E*. The central tapered core *D* is attached to the mold and makes the perforation in the coal cake; this core also helps to compress the mixture in the mold. To prepare the mixture for

MOLD USED FOR MAKING COAL BLOCKS

the mold, the coal dust is mixed with the binder and sufficient water is added to make a stiff mass; this mixture is then spread out to the desired thickness. The mold is pressed into the prepared layer; when the mold is withdrawn the compressed cake is ejected by means of the handle *E*. This device is primarily intended for domestic users who have a surplus of coal dust which they are unable ordinarily to utilize. It is for use on a small scale and during times of scarcity of fuel, or when coal is high in price. It might offer suggestions to those living near accumulations of coal dust.

California Coal That Is Rich in Oil

For many years lignite mined near Ione, Calif., has been used as fuel, though it contains a large quantity of moisture and therefore does not burn very well. Recently, however, on account of its resemblance to some oil shales that are apparently similar to cannel coals, this lignite has been tested by the United States Geological Survey, Department of the Interior, to determine whether it would not yield oil on destructive distillation. The results of the tests show that the best of the lignite, when destructively distilled, will yield 62 gal. of oil to the ton and, as a byproduct, at least 18 lb. of ammonium sulphate, which is a valuable fertilizer. This lignite is remarkably "fat." Although it contains 46 per cent. of moisture, analysis made by the Bureau of Mines shows that it contains also 31 per cent. of volatile matter and 16 per cent. of fixed carbon. The ash amounts to only 7 per cent., and the heating value is 6060 B.t.u. Although the bed containing this lignite does not appear to underlie a large territory, it is doubtless destined to receive attention sooner or later as a possible source of oil and gasoline.

[5]Selvig, W. A.: Fusibility of Coal Ash from West Virginia coals; *Coal Age*, Vol. 15, No. 1, 1919, pp. 12-16.

Lubrication of Air Compressors

By H. V. Conrad
Secretary, Compressed Air Society, New York

SYNOPSIS — *The oil for lubricating air-compressor cylinders should have a body of such weight as will separate the parts that have relative motion. It should carbonize but little if at all. Asphaltic base oils give a fluffy carbon, while a hard and adherent carbon is formed by those of paraffin base. Oils of high flash point are likely to produce carbon deposits. The author discusses rate of feed and carbon-cutting methods and concludes with some remarks on steam-engine lubrication.*

THE cylinders of air compressors can only be said to be satisfactorily lubricated when friction is reduced to a minimum and when the carbonization of the oil is eliminated as far as possible. If friction is to be avoided to a proper degree it will be necessary to choose an oil having sufficient body to sustain the weight of the moving parts and so form a seal between the rings of the piston and the walls of the cylinder. But the oil must not be so viscous as to absorb power needlessly.

The oil used in air cylinders apparently is always subject to a certain carbonization. It is well, however, to state just why that carbonization should be reduced to the lowest limits possible. The reasons are as follows: The deposits of carbon resulting from the carbonization of the oil accumulate on the cylinder valves, on the cylinder passages, in the pipes, and eventually in the air receiver.

In the early stages of their formation they are sticky, but they become hard and flinty later. These carbon accumulations cause sticking or incomplete closing of the valves which, in consequence, fail to act properly. This is probably the chief objection to the carbonization of the oil used in the cylinder.

The formation of excessive carbon deposits is likely to be due to any one or more of the following causes:

1. The ill-advised use of an oil, such as a steam-cylinder oil, which easily decomposes in the heat of the air cylinder.

2. The use of oils of too great a viscosity—commonly referred to as "too heavy oils." These do not atomize readily and therefore remain too long upon the hot cylinder walls, thus baking down to sticky carbon deposits.

3. The use of too much oil, which has the same effect as the use of too heavy an oil as far as the carbonization is concerned.

4. The failure to provide a proper screen over the air intake of the compressor, thus allowing free entrance of dust.

Not only does carbonization cause a sticking of valves and a choking of air passages, but it menaces the equipment with possibilities of fire. Carbon particles torn loose from such deposits may become incandescent from causes against which the manufacturers of the compressor cannot provide. If these incandescent carbon particles happen to come in contact with "oil-vapor" given off by the lubricating oil, a fire may possibly be started the menace of which would be small or large, depending upon how much carbon had been allowed to accumulate in the compressor and in the piping leading to the receiver. If these parts are kept properly cleansed at all times there should be no danger. Oil vapor is given off from a lubricating oil at a certain temperature called its "flash point," just as steam rises from water at a certain temperature.

To a large extent the lubricant for an air cylinder should be selected with reference to the cylinder temperature it must withstand. Knowing the air pressures the temperatures in the cylinder at the end of the compressor stroke may be ascertained with fair accuracy, as shown in Table I both for single-stage and two-stage (or compound) compression, the free air being assumed to enter the cylinder at 60 deg. Fahrenheit.

TABLE I. CYLINDER TEMPERATURES AT END OF PISTON STROKE

Air Compressed to a Gage Pressure, Lb.	Final Temperature, Single Stage, F.°	Final Temperature, Two Stage, F.°
10	145	....
20	207	....
30	255	....
40	302	....
50	339	188
60	375	203
70	405	214
80	432	224
90	459	234
100	485	243
110	507	250
120	529	257
130	550	265
140	570	272
150	589	279
200	672	309
250	749	331

The temperatures given in Table I will not always occur in actual practice, for the water jackets of the cylinders and radiation from the surfaces will tend to lower the temperature at the higher pressures. At a pressure of 50 lb. and lower, the heat is quite likely to be greater than that given if the compressor is run at a high speed and is not water-jacketed.

Relation of Flash Point to Cylinder Temperature

The natural inference of the reader, after noting the temperatures in Table I, is that he must select an air-cylinder oil of a flash point just above the maximum temperature commonly encountered within the air cylinder. As a matter of fact, this is not so.

The air-cylinder temperatures are useful because they aid us in selecting an oil which will resist breaking down into carbon when used in the lubrication of the cylinder. Such temperatures cannot be used as indicating the highest allowable flash point for a lubricant safe to use in the air cylinders.

In general, for average conditions, the oil should be a pure mineral oil of medium body and of the highest quality. It should not be compounded with fixed oils, such as those of animal or vegetable origin. It should, moreover, be carefully filtered in the final process of manufacture. Still a range of composition is nevertheless permissible in lubricants used for the lubrication of air compressors.

A distinction must be made between oils having a paraffin base and those having an asphalt base. Some

lubricant manufacturers claim that one class of oil is as desirable as another for the lubrication of the cylinders of compressors provided that both of them in the process of manufacture have been properly filtered so as to remove all carbon-forming elements. If, however, any carbon should be formed by the asphaltic base oils it will be of a light or fluffy nature, whereas that formed by oils having a paraffin base will be adhesive, hard and flinty.

To aid the operator in specifying what qualities should be possessed by a lubricant for average duty in air cylinders, Table II is given. I would suggest that

TABLE II PHYSICAL TESTS OF PARAFFIN-BASE OILS

	Minimum	Average	Maximum
Gravity, Bé.	28 to 32 deg.	25 to 30 deg.	25 to 27 deg.
Flash point, open cup	375 to 400 deg. F.	400 to 425 deg. F.	425 to 500 deg. F.
Fire	425 to 450 deg. F.	450 to 475 deg. F.	475 to 575 deg. F.
Viscosity (Saybolt) at 100 deg. F.	120 to 180 sec.	230 to 315 sec.	to 1500 sec.
Color	Yellowish	Reddish	Dark red to green
Congealing point (pour test deg. F.)	20 to 25 deg. F.	30 deg. F.	35 to 45 deg. F.

those oils which have ranges such as are described under the column marked "Minimum" should be used for light duty where low pressures and temperatures will be encountered. Any paraffin-base lubricant intended for use in "standard air compressors" should be within the ranges set forth under the column marked "Average." The following types of machines are classified as "standard air compressors":

1. Low-pressure machines compressing air to 100 lb. or less. These may be either small-sized single-stage units or larger-sized compound machines.

2. High-pressure machines which are constructed with the proper number of stages, so that no excessive temperatures are ever reached.

In other words, the lubricant which can find its appropriate place in the column marked "Average" (Table II) is always recommended unless a compressor manufacturer specifies in his literature that an oil of high flash point should be used to meet conditions peculiar to his machines. It is thus obvious that it is never necessary that a lubricant should possess a flash point as high as 500 deg. unless abnormal conditions of high temperature prevail. Oils of so high a flash point have an unusual tendency to produce the carbon deposits that we are so anxious to avoid.

The asphaltic-base lubricating oils are considered separately for the reason that the lower limit of gravity

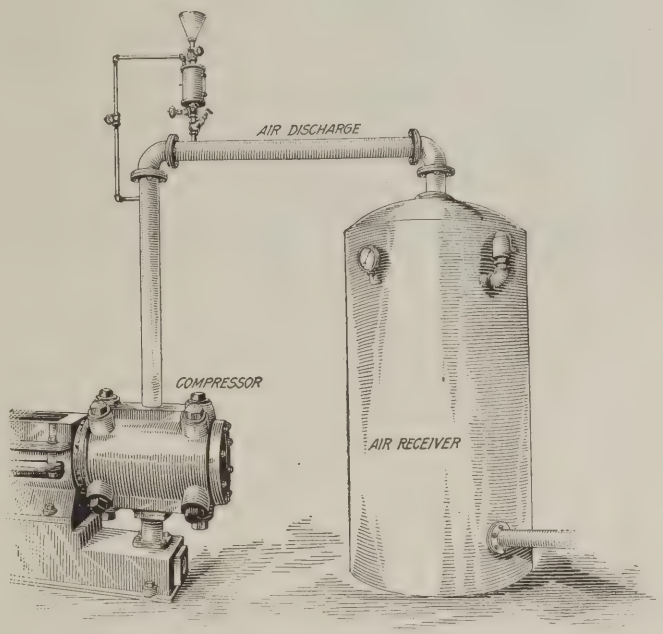


TABLE III. PHYSICAL TESTS OF ASPHALTIC-BASE OILS

	Minimum	Average	Maximum
Gravity, Bé.	20 to 22 deg.	19.8 to 21 deg.	19.5 to 20.5 deg.
Flash point, open cup	305 to 325 deg. F.	315 to 335 deg. F.	330 to 375 deg. F.
Fire	360 to 380 deg. F.	370 to 400 deg. F.	385 to 440 deg. F.
Viscosity (Saybolt) at 100 deg. F.	175 to 225 sec.	275 to 325 sec.	475 to 750 sec.
Color	Pale yellow	Pale yellow	Pale yellow
Congealing point (pour test, deg.)	0 deg. F.	—0 deg. F.	—0 deg. F.

stated in Table II—namely, 25 deg. Bé.—eliminates this entire group from consideration, which is not the intention of this article. As a guide for the selection of suitable oil, Table III is given. In general, the recommendations of Tables II and III cover the situation as well as possible. Special cases will, of course, require investigation and special consideration before recommendations are made.

The quantity of lubricating oil to feed to the air cylinders of compressors cannot be stated in exact terms. This is because of the varying viscosity of different oils, the heat of compression and the size of the cylinder. It may be stated in general, however, that, after the cylinders have acquired smooth and polished surfaces, the quantity should be reduced to the lowest limit, to avoid the possibility of the accumulation of carbon and sooty deposits. The basis of quantity given in Table IV is recommended, subject to modifications.

It should be carefully noted that the results in the last column of Table IV are based on the assumption that, under average conditions of temperature and with the usual range of oil viscosities, a pint of oil will

ARRANGEMENT FOR FEEDING SOAP SUDS INTO AIR DISCHARGE TO CUT CARBON DEPOSITS

average about 16,000 drops. The figures are offered merely as a rough guide. Every individual must exercise his own judgment in modifying them wherever his working conditions are unusual.

A leading authority on compressor engineering contributes the following: "The best way to determine the proper amount of lubrication is to take out the valves from time to time and examine the cylinder. All parts should feel oily. If they feel dry, the lubricators should be adjusted to feed a little more oil, whereas if oil lies in the cylinder or its parts, the quantity fed by the lubricators should be reduced. By thus examining the machine a few times the proper amount of any particular lubricant under the conditions of operation can be determined. It is better to use this method of determining the number of drops needed than to adopt, without experiment, any number of drops prescribed by authority for any given oil and conditions. This is a better way to finally determine the quantity of oil required than by adopting, without this experimenting, any predetermined number of drops."

The best of lubricating oils will cause the deposit of enough carbon in the compressor system to necessitate periodical cleansing. For the removal of carbon, the machine operator should confine his efforts to the use of soapsuds. A good cleansing solution is made of 1 part soft soap to 15 parts water. About once a week the suds should, for a few hours, be fed into the cyl-

TABLE IV. QUANTITY OF AIR-CYLINDER LUBRICANT REQUIRED PER 10-HOUR DAY

Diam. of Cylinder, Inch	Size of Cylinder, Inch	Displacement per Minute, Cu.Ft.	Piston Speed, Ft. per Min.	Sq.Ft. of Cylinder Wall Swept by Piston	Drops Oil per Minute	Drops Oil per 10 Hours	Sq.Ft. Oil per Drop	Number Pints Oil Required per 10 Hours
8	8x 8	120	344	718	1	600	718	0.0375
12	12x12	320	408	1230	2	1200	613	0.0750

24	24x24	1730	550	3450	6	3600	575	0.2250
30	30x30	2940	600	4700	8	4800	590	0.3000
36	36x36	4550	644	6070	10	6000	607	0.3750
42	42x42	6700	696	7600	12	7200	633	0.4500

Figures of last column are based upon an estimated 16,000 drops per pint of oil at 75 deg. F.

inders in place of oil, either by means of a hand pump or through the regular lubricator.

The suds should be fed about ten times as rapidly as oil. The cleanliness of the air valves when inspected, as they should be periodically, will indicate whether greater or lesser applications of the soapsuds should be made. After using soapsuds, open the drain cock of the air receiver (and of the intercooler in the case of compound machines) to draw off any accumulated liquid. Before shutting down the machine, oil should be used for at least a half hour so as to prevent the rusting of the cylinder and its fittings. Never use kerosene, gasoline or lighter oils in an air cylinder for any purpose whatever, because of their volatile nature in the presence of heat.

It often happens that oil, carbon and other foreign matters are deposited in the lines through which the air is discharged and also in the air receiver. A practical method of cleaning these is shown in the illustration, where a receptacle made of 6-in. pipe is shown set on top of the discharge pipe. The diagram shows plainly the construction and what the different parts represent.

If, while the compressor is running, a mixture of 1 lb. of lye and 18 lb. of water is passed into the discharge line at the rate of 60 or 70 drops per minute, this will eat out all the carbon which has accumulated on the surface of the pipe and in the receiver; and if the blow-off valve on the receiver is open, all this foreign matter will be discharged therefrom. This cleansing solution can be used every month or two, the frequency of its application depending on the amount of carbon that may be deposited in the receiver.

Steam cylinders should be furnished with about four times as much oil as air cylinders, because the oil in the former case is constantly being washed away by the steam. Of course, conditions vary and make the ratio somewhat variable.

A pint of steam-cylinder oil will furnish from 5000 to 8000 drops, the number depending on the viscosity of the oil. Taking an average of about 6500 drops and assuming that four times as much oil is needed as for air cylinders of the same size working at the same piston speeds as given in Table III, the quantities of oil which should be fed to steam cylinders are given in Table V. The figures are approximate only, and will vary with the steam conditions, the kind of oil used and its method of introduction into the steam; also with the boiler compound carried by the steam into the cylinder. When the operator of an air compressor succeeds in obtaining lubricating oils that are giving satisfactory results, he should be cautious about making a change to other grades, particularly if cheapening the cost is advocated by purchasing or selling agents.

TABLE V. NEEDED OIL FOR STEAM-CYLINDER LUBRICATION

Number of Drops Needed per Minute	Size of Cylinder, in In.	Number Pints Oil Needed per 10 Hours
4	8x 8	0.4
8	12x12	0.75
16	18x18	1.5
24	24x24	2.25
32	30x30	3.0
40	36x36	3.75
48	42x42	4.5

But if a change is decided on, the performance of the new lubricants should be most carefully checked up before damage can occur to the rubbing surfaces of the compressors, and care should be taken to see that no increased amount of deposit collects on the inside walls of the air receiver.

The quickest way to solve the problem as to the use or rejection of any new air-cylinder lubricant safely and satisfactorily is to submit the matter to the local experts of any reputable lubricating company and to be governed by their recommendations. This advice should, however, be based on the considerations mentioned in the foregoing statement.

Use of Electric Power in the Mining of Anthracite Coal

One of the big anthracite companies, committed to an electrical policy, is systematically distributing the various power costs of operation at its plants. Much interesting information is thus obtained for comparison with former steam costs for the same duty. In this connection a paper read before the American Institute of Electrical Engineers by J. B. Crane is most timely. In this paper, Mr. Crane states a certain anthracite mine had meters installed for the different services for one year and the following average figures were obtained:

Operation	Kw.-Hr. per Gross Ton of Coal Produced
Haulage	1.73
Ventilation	1.62
Drainage	1.30
Lighting (including charging station)	0.12
Hoisting	1.02
Air compressor	2.11
Breaker	4.75
Total	12.65

The mine produced 558,394 tons of coal for the year in question and was doubtless selected as a plant presenting average conditions of cost of producing coal. If we assume 12 kw.-hr. per ton of coal produced, then there would have been required in 1917 (with a total anthracite tonnage of 89,720,982), if all the coal had been produced electrically, 1,076,652,000 kw.-hr. As a matter of fact 215,000,000 kw.-hr. were actually used in 1917 in electrically operated anthracite mines from central station and mine plants. Thus 861,652,000 kw.-hr. is the balance which would have been necessary to produce the remainder of the anthracite electrically.

In the mining and preparation of anthracite, reports have shown for years that some 10 tons of coal are required for power purposes for every 90 tons sent to market. Therefore in 1917, to produce the 89,720,982 tons of coal, 10 per cent., or 8,972,098 tons, were burned under boilers. If we can produce 1 kw.-hr. from 2½ lb. of small anthracite in large power stations, then 961,665 tons of coal would supply the 861,652,000 kw.-hr. noted in the preceding paragraph. Thus a saving of 8,010,335 tons would be effected, and this amount of coal would be released for sale.

FIG. 1. FRONT VIEW OF THE MAIN BUILDING OF THE PITTSBURGH STATION OF THE BUREAU OF MINES

The New Pittsburgh Station of the Bureau of Mines—I

By George W. Harris
Editorial Staff, *Coal Age*

THREE quarters of a million employees labor in and around the coal mines of this country, the hazardous nature of their labor demanding that they be safeguarded by every reasonable precaution. This necessity was long recognized, but it took a series of terrible mine explosions with attendant harrowing circumstances to emphasize the need of positive action.

The history of coal mining in America furnishes a striking illustration of the permanent benefit that may be brought about by disaster. The great loss of life following the explosion in an anthracite mine at Avondale, Penn., on Sept. 6, 1869, aroused public sentiment in that commonwealth to such an extent that legislative action begun at that time finally gave the state a set of mining laws and a system of inspection that brought great relief to both operator and miner.

England, France, Belgium and Germany all have established bureaus in their respective countries that are attaining most satisfactory results. Especially in France and Belgium was it necessary to surround the miner with every safeguard, as here are notably deep mines and gaseous coal seams; yet the death rate among the miners of these countries was far below that of our own country, in which an average of 3½ men per 1000 employed were killed in mines in 1908.

The Bureau of Mines was organized by its first director—the late Dr. J. A. Holmes—who also planned the new building that is the present home of the Pittsburgh station. It is particularly appropriate that the field headquarters of the Bureau should be located in Pittsburgh, the center of the greatest coal and coke and iron and steel section of the country. The new Pittsburgh station building is located in the Schenley Farms district, in the technical and educational atmosphere of the city. The property of the Carnegie Institute of Technology abuts on the south and east; the extensive building that houses the library and other benefactions of Andrew Carnegie lies to the west; on the crest of a not distant hill, a little to the north of west, is the University of Pittsburgh and the Mellon Institute.

The Pittsburgh station building is shown in perspective in Figs. 1 and 2, and the plans of the various floors are given in Figs. 3, 4, 5 and 6. The architecture is severely plain and businesslike, with an ornamental doorway at the main entrance on the north elevation (see Fig. 1). The main station building somewhat resembles the letter H, consisting of a longitudinal central building and two transverse wings, as may be seen in the illustrations. This building has only recently been taken over by the Bureau, accessory plant has not completely emerged from the construction period and the laboratory work is being reorganized and systematized; war work that has been carried on at the station is being wound up and preparations are being made to carry out the plans considered when the building was authorized.

The nature of much of the work done at the Pittsburgh station demands that the building containing the laboratories and workshops be substantial and of fireproof construction; furthermore, valuable records and results of years of research, also the samples stored

here, all dictate that there be a practical elimination of the fire risk. The building was therefore built with this in view. Imitation granite forms the side walls to the first floor, above which is reinforced concrete faced with buff brick; the floors are tile and concrete overlaid by hardwood in the offices and some of the laboratories; the partitions are of gypsum block. The main building corridors have floors of stained cement and marble mosaic. A slate roof caps the structure.

The dimensions of the Pittsburgh building suggest roominess. The central part of the station measures 59 x 240 ft., and each of the east and west wings is 46 ft. wide and 211 ft. long. The central portion and east wing were laid out for special allotment of rooms for certain work to be done; the west wing was made with rooms communicating, which permits of their being used as a suite or individually. The central portion of the building is mainly given over to administrative officials and affairs; the east wing is distinctly the chemical section and contains the various laboratories and offices; the west wing is appropriated largely by the mechanical department, the entire basement eventually constituting a mechanical laboratory that is open to the level of the second floor. Over this latter laboratory are smaller laboratories and the offices of the mechanical and electrical sections.

Some authority has stated that a chemical laboratory should include pipes with a building constructed around them. The significance of this comment is evident to the initiated and should be plain to anyone when it is known that a modern laboratory service often includes hot and cold water, compressed air, vacuum and natural and artificial gas, also electrical current. In connection with the Pittsburgh station laboratory considerable thought was given to the service problem. All main service pipes and electrical wires come into the basement of the building in a tunnel which continues under the basement corridor; from here the pipes pass through a vertical shaft up to the first and second floors. Under the first and second floor corridors are concrete passages connecting with the pipe shaft, and service mains extending the length of the building are run through these secondary passages. Special provision is made for branch pipe lines; 2 x 12-in. joists are in position under the wooden floor at right angles to the corridors, and branch pipes and wires are readily carried from main lines between these joists, up through the floor to the laboratory tables or benches. Drains from the benches and sinks are carried to vertical risers of acid-resisting fiber pipe leading down to a terra cotta drain in the basement tunnel.

FIG. 2. GENERAL VIEW OF BUREAU OF MINES BUILDINGS, LOOKING NORTH

The efficient and thorough ventilation of a laboratory, especially the hoods, is most important. This feature of the station chemical laboratory has been most satisfactorily worked out and was put to a severe test recently. In the war-work investigations of gas masks and respirators, some powerful poison gases were used; and their complete and direct removal from that part of the building where they were used was most imperative. The ventilating system of the laboratories of the entire wing includes four vertical flues equally distributed along the length of the building and connecting with all hoods by galvanized-iron air ducts painted inside with an acid-proof preparation. These vertical flues

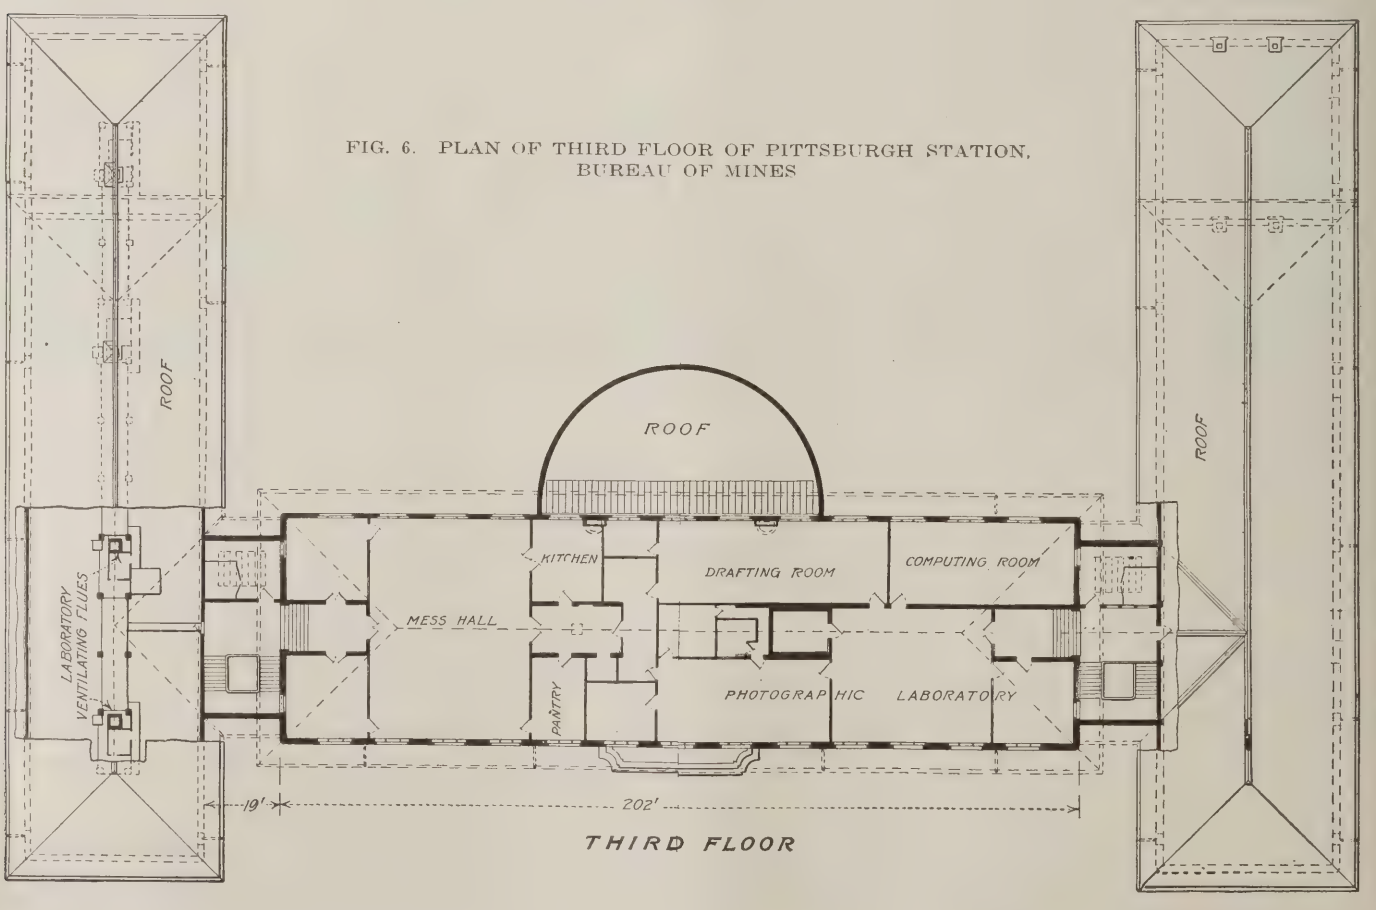

FIG. 6. PLAN OF THIRD FLOOR OF PITTSBURGH STATION, BUREAU OF MINES

extend to the loft over the chemical wing; here fans exhaust the fumes from the laboratory and force them out of the building through four vents in the roof.

The basement of the chemical (or east) wing is largely given up to storage of unused equipment, petroleum products and coal samples. A great number of coal samples have been taken from seams in mines throughout the country, and all these have been carefully preserved, making a valuable collection. In time they cannot be used for B.t.u. determinations, but for some purposes such as ash-fusing tests they answer the same purpose as freshly gathered samples. Coal samples are prepared in the basement, and gas masks are tested in a special gas chamber fitted up for the purpose. The disposition of other space is indicated on the plans.

On the first floor of the center building are the offices of the administrative and clerical forces. In the bay is an auditorium capable of seating 228 persons; it is at the service of the mining and scientific public at any time, upon application. The stage is equipped for lantern slide, moving picture and demonstration work of various kinds. The conference room on this floor is also available for small gatherings of scientific or technical men. The appointments of the room are in keeping with the purposes for which it was designed. The accompanying floor plans clearly note the uses to which the space on the second and third floors is put.

The mechanical laboratory takes up the whole floor space in the basement of the west wing. It is one large open room and of a height equal to the basement and first floor rooms in the center building and east wing. This laboratory is equipped for all kinds of mechanical work or testing. The floor is cement. On one side of the room provision will be made for a run of over 200 ft. in length on which rope tests and experiments can be made. On the other side of this laboratory is a service tunnel just below the floor level; connecting with the tunnel and at right angles to it are six cross trenches; the latter are 2 ft. deep and 3 ft. wide. The tunnel and trenches carry the service pipes and wires, which thus are distributed convenient for use at any part of the laboratory. At present the north end of the mechanical laboratory is used as a temporary machine and carpenter shop; the south end is now occupied by the ordnance department, which is conducting physical examinations of metals. The plan of the second floor of the west wing is self-explanatory as to disposition of space.

An important feature of the Pittsburgh station is the power plant that occupies the low building in the immediate foreground (see Fig. 2). The steam-generating end of this plant is a temporary arrangement. Two Babcock & Wilcox boilers are set independently with Sewell-type baffling; they are fired with Playford, type B, chain-grate, mechanical stokers that are 6 ft. wide and 10 ft. long. Another boiler—a 208-hp. Parker—is being erected, and this unit will be fired with an Illinois, chain-grate, mechanical stoker, 5 ft. wide and 10 ft. long. Pittsburgh seam screenings are fired under the boilers.

A feed-water heating system is used, the temperature of the city water being raised to about 210 deg. F. and then pumped into the boilers. The water is slightly hard and a Permutit water purifier system has been installed. Eventually the steam-generating plant will be in an addition to this building, on the ground level. This new arrangement will permit of satisfactory mechanical handling of coal and ashes. At present this work is done partly by hand; the coal is shoveled by hand from a railroad car into a skip that runs up the inclined track (see Fig. 2) and dumps it into a bin. Further handwork is necessary in the boiler room to fill the stoker hoppers at the grates. This expensive work will be done away with in time.

Electric current is generated in the center room of the power plant, first floor, by three 18 x 24-in. single Nordberg engines direct-connected to three-phase, 60-cycle, 440-volt, 200-k.v.a., revolving-field, General Electric alternators.

For ordinary service in the laboratories, 110- or 220-volt direct current is furnished by a 50-kw. Crocker-Wheeler motor-generator set—a synchronous motor in control and a 110- and a 220-volt direct-current generator being mounted on either side; all this apparatus is mounted on a common base. For direct-current circuit-breaker and switch tests, a direct current of 220 volts is supplied by a De Laval turbo-generator set; the turbine driving two 220-volt, 110-kw., direct-current generators.

In the east end of the power building is the fuels laboratory. Tests will be made here soon on house-heating boilers, to determine the heating value of coal in terms of wood. This problem is of practical interest outside of army circles. Under the first floor of the power building are pipe and wire galleries and also rooms for apparatus accessory to the machinery and steam plant above, such as a pressure oil-circulating system and so on. The main building of the Pittsburgh station is heated by exhaust steam from the engines in the power building; and the steam mains go from one building to the other through a tunnel.

The building shown in Figs. 1 and 2 is the first of a group; others are contemplated, and construction is at present proceeding during suitable weather on additions to the plant. A gallery for testing large explosion-proof apparatus is being completed near the end of the chemical wing of the station; the structural steel frame of the gallery building is shown in Fig. 2. Adjacent to the gallery is to be a garage—the materials for the building are on the ground. The garage will house automobiles, mine rescue trucks and passenger cars for jitney service between Pittsburgh and the Bruceton experiment stations; this building will include a tire and repair shop. Plans are being completed for an explosives magazine designed to hold quantities of explosives temporarily stored here awaiting chemical analysis and tests.

By referring to Fig. 2 it is evident that the Bureau of Mines building faces one of the fine residential sections of Pittsburgh. When the idea was suggested that this building be erected in the Schenley Farms district of the city, considerable opposition developed on the part of those owning homes here. To the average Pittsburgher the thought of a mines building going up in their midst would be somewhat alarming. However, little difficulty was finally experienced in acquiring a fine site for the station, which bids fair to considerably enhance the prestige of the educational and technical reputation of the Iron City.

(*To be continued*)

Governor Sproul Withdraws His Criticisms of the Anthracite Industry

On Mar. 13 Governor Sproul of Pennsylvania, much perturbed at the increased cost of anthracite, asked the Attorney-General to tell him what powers he had to inquire into the cost of anthracite. On Aug. 4 the governor, having assured himself that the price increase was justified, much to the credit of his reputation as an honest and fearless public servant, made the statement given below.

SINCE the announcement of the proposed raise in the price of domestic sizes of anthracite coal at the mines, last month, I have given a great deal of time to the making of a businesslike personal investigation of the anthracite situation. In this I have received every coöperation from the operators and from others interested in the question. I have made the investigation personally as a business man and as a state official rather than by utilizing the more ponderous implement of a legislative committee, because I was convinced that it was essential, in view of the commercial interests involved, that decision should be given promptly.

Had Access to Engineers' Reports

In my inquiry I have had access to the reports made by the engineers and experts employed by the United States Fuel Administration. These reports are very complete and their determinations are recent and up to date. I have also had the sworn figures of the producing corporations, both the railroad operators and the independents, before me and have had the benefit of the advice and experience of some of those who assisted the Federal Fuel Administrator in his determinations.

H. A. Garfield, the United States Fuel Administrator, when he relinquished active control over coal prices on Feb. 1 of this year, made a statement in which he said among other things:

"Had the Fuel Administration's active control over maximum prices on anthracite coal been continued the cost examination above referred to shows that it would have been necessary, on the basis of the present wage scale, to raise these maximum prices possibly as much as 50c. per ton above those last fixed by the Government, in order to prevent financial embarrassment and perhaps the closing of companies producing a substantial percentage of the necessary anthracite output. Such a curtailment of production would eventually result in the demand exceeding the supply to such an extent as to increase the prices much higher than they would be if that supply was continued."

I am convinced that Dr. Garfield's judgment in this matter was correct and that the action of the producers in announcing a gradual increase of 10c. a ton for five months, beginning May 1, is justified, considering all of the conditions confronting the trade. We are all anxious that the present wage in the anthracite regions be maintained, as this industry in one way or another affords employment and sustenance to almost one-tenth of our industrial population in Pennsylvania. It is also a fact to be thoroughly considered that only about one-eighth of the anthracite coal mined in Pennsylvania is consumed in this state, the balance going outside of the limits of the state. The Federal Fuel Administration's experts showed that the cost of mining and preparing anthracite coal has increased 52 per cent., while the price at the mines has increased only 30.5 per cent.

Willing to Coöperate

Several of the larger independent operators and some of the so-called railroad interests were willing to defer the beginning of the increase until July 1, instead of May 1, had I so requested. I feared to insist upon this, however, as it would have meant a derangement in the trade throughout the entire anthracite-using section and would undoubtedly have worked hardship upon operators and the throwing of many people out of work by preventing early buying of anthracite and its storage in cellars for next winter's use.

There has been a marked falling off in the production of coal during February and March, many mines being on short time and others closed. It would be dangerous, therefore, to delay the settlement of the question longer for the usual mining operations during the spring and summer would be reduced and a shortage in coal and consequently higher prices would result next winter. My feeling is that everyone who can do so should lay in coal now.

There are other elements entering into the cost of anthracite coal at the homes of our people which need some sort of regulation and control. There are great inequalities in the railroad rates as planned by the Federal Railroad Administration, and, of course, a considerable part of the increase in the price of coal has been due to these increased rates for carrying domestic coal to the user. For instance, the freight rate to Reading is $1.90, although the haul from the Schuylkill region is but little over fifty miles, while the same rate prevails to Philadelphia, nearly sixty miles further. If our railroad situation is ever unscrambled and the state ever again has authority over its interstate business an investigation must be made to iron out these inequalities and give the people their rights in the matter.

Distribution Charge High

The charges for distribution, which were fixed at a very high figure during the extraordinarily severe winter of 1917-1918, when heavy snows and the worst weather in a generation made the handling of coal extremely difficult, still remain in force in most places, although in some cities of the state reductions of as much as 50c. per ton have been made in the delivery charges. The dealers have their troubles, too, in increased expenses for labor and materials, but it would seem that there is generally room for reductions in the distribution charges which will at least make up and perhaps exceed the increase which is necessary at the mines.

It would seem that there should be some continuing authority over the fuel situation to prevent runaway

markets, extortion and to maintain the trade on an equitable basis, fair to labor, producer, dealer and consumer.

It would also seem that our larger communities might very well be given the right to establish coal markets for supplying their own citizens. Well conducted public fuel markets would likely be able to save the citizens of our larger communities as much as a dollar a ton upon domestic fuel coal.

[It may be said for the retail dealers that their prices were probably kept up in anticipation of a heavy snowfall which would make such prices as they were charging wholly inadequate during the long period in which the snow might be expected to encumber the streets. No one knew till spring was well on its way that the weather would be mild.—EDITOR.]

Instrument for Locating Entombed Miners

The geophone, a listening instrument invented by the French during the war to detect enemy sapping and underground mining operations, and for the location of enemy artillery, is now being used by the Bureau of Mines as a possible aid in locating miners who have been entombed after a disaster. This instrument was further developed by United States engineers and is now used by the bureau according to plans drawn by these engineers. Alan Leighton, of the bureau, has charge of investigations being conducted with the geophone by the department with which he is connected.

The instrument, though small, is essentially a seismograph, since it works on the same principle as the ponderous apparatus with which earthquake tremors are recorded. It consists of an iron ring about 3½ in. in diameter; within the center of this ring is suspended a lead disk which is fastened by a single bolt through two mica disks, one forming the top and the other the bottom cover of the ring. Outside of each mica disk is a brass cap piece fastened with bolts to the iron ring and serving also to hold the mica disks in place. The top brass cap has an opening in its center to which is fixed a rubber tube leading to a stethoscopic earpiece.

The geophone is simply an air-tight box in which is suspended a lead weight between two mica disks. In operation, if the instrument is placed on the ground and anyone pounds or digs in the vicinity, then energy is transmitted as wave motion to the earth and these earth waves shake the geophone case. The lead weight, on account of its mass and because of its being suspended between the mica disks, remains comparatively motionless. Thus relative motion is produced between the instrument case and the lead weight, with resulting compression and rarefaction of the air in the instrument. This rarefaction and compression is carried to the ear drum by the rubber tube and stethoscopic ear piece. It is customary to use two instruments, one for each ear.

When the two instruments are used, it has been found that the sound is apparently louder from the instrument nearer the source of the sound. It is evident then that by moving the instruments around, a point can be found where the sound will be of the same apparent intensity in both ears. The direction of the sound is then on a perpendicular to the line connecting the centers of the two instruments either in front of or behind the observer. Further observation will show which side. Direction of sound is quite accurately determined in this way. The sound is not actually louder in one ear than in the other, but the ear is capable of distinguishing the difference in time at which the sound arrives in the two instruments.

The Bureau of Mines engineers have done considerable experimenting with the geophone, determining the distance that different mining machines could be heard through clay, shale, coal and strata overlying coal beds. Measurements were also made of the energy required to be given to various tools that blows might be heard through definite distances of rock and coal. The shock waves resulting from the discharge of explosives were also investigated. To give some idea of the sensitiveness of the instrument, it may be said that pounding with a pick on bituminous coal has been detected a distance of 900 ft. and the direction determined; pounding with a sledge has been heard as far as 1150 ft. These measurements were made in the Pittsburgh coal seam, which is somewhat harder than most other bituminous coal beds. One interesting feature of the instrument is that the sound as transmitted to the ear is characteristic of the instrument producing the sound.

It is thought that the geophone possibly will be of great value to mine rescue crews who may enter mines for exploration, and to locate miners who may have been entombed after a disaster. The distance at which sounds can be heard depends greatly on the character of the coal upon which a man is pounding; intervening rooms and entries seem to have surprisingly little effect in interrupting sound or in confusing the determination of direction. On the other hand, any wind blowing outside the mine greatly interferes with the successful operation of the instrument on the surface. Futhermore, dust tends to dampen the transmission of sound; and since mine tracks often either rest on such material or are surfaced with it, sounds are not usually transmitted well by rails. The same is true of pipe lines which are buried in mine dust; however, when pipes are supported on ties or fastened to props, pounding on them can be heard great distances. Miners are well aware of this and frequently signal to the surface by hammering on pipe lines up shafts and slopes.

After the bureau has completed its investigations, a course of instruction in the use of the geophone will be developed and recommendations will be made as to the best procedure for rescuers to follow when using the instrument, and also what entombed miners should do to assist toward their rescue.

Wasted Fuel in Factories

In most factories the ashes and waste from boiler and other furnaces carrying a variable amount of usable fuel is either taken to a common dump or is carted away without any attempt at recovery of the useful portion, even sifting not often being done. In this way a loss of fuel occurs, and it would seem that decided improvement could be effected in the treatment of both factory and domestic fuel wastes.

Probably a combination of dry and wet separation would give the best results, the material being graded and to some extent separated dry by means of screws, as in a coal washery, and afterward separated in wet jigging or other machines so far as the heavy waste is concerned. Metals and other material passing over, say a 2-in. mesh screen might well be hand sorted. Fine stuff below that passing a ¼-in. mesh screen could be left untreated. The result of treating the grades between ¼-in. and 2-in. would be fuel and waste.

Railroad Fuel Policy Still Subject of Much Acrimonious Debate

Little progress has been made during the past week in the controversy over the purchasing policy of the Railroad Administration. The matter has been the subject of bitter discussions. Officialdom is divided, and there is a diversity of opinion among coal operators and steel makers. Director General Hines apparently is of the opinion that the low-cost mines can produce all of the coal that is needed at this time and is opposed to adjusting prices so as to permit other properties to operate. His view apparently is that the low-cost operations will absorb such labor as may be released from higher-cost properties, to say nothing of the increased employment which would be made possible if coal and steel costs were reduced.

The National Coal Association has not replied to Director General Hines' last statement alleging selfish motives on the part of the coal operators. It is the intention not to dignify it with a reply.

Investigation Bureau of Fuel Administration Will Cease Work on May 1

The Bureau of Investigation of the Fuel Administration will close out its work May 1. Any cases which may be pending on that date will be turned over to the legal division. When the Bureau began its work, there were 1800 jobbers of coal in the country. This number increased to 4800, largely as the result of the licensing system and the 15c. a ton addition to the price.

Of that large number in the jobbing business, all but eighty have reported according to the regulations. An analysis of those eighty, however, shows that there were no intentional violations of the regulations. Most of the number is made up of those who expected to do a jobbing business but through failure to obtain coal did not actually handle any tonnage.

More than 30 per cent. of the workmen in coal mines, it is believed, are non-resident aliens. This means that a large amount of work will fall to coal operators under the new revenue law, in which they are charged with the duties of withholding income tax at the source.

The Government, on Apr. 9, filed its brief in the Supreme Court of the United States in the case of the United States vs. the Lehigh Coal and Navigation Co. The case, which has been in the courts since 1915, revolves around an alleged payment of rebates by the Central Railroad Co. of New Jersey to the coal company.

Some Interesting Comparisons in Prices of Basic Commodities

How far the cost of living, for individuals and industries, has gone down or is likely to go down is again brought to the fore by the announcement of a price readjustment for the steel industry. The new schedule of steel prices is interesting, not only for its actual figures, but for the results obtained from a comparison with prices ruling in January, 1914, before a world war became the main price factor.

Such a comparison indicates that even under the new schedule steel prices show a tremendous increase, surpassing the advance in America's other great basic commodity, coal, whether anthracite or bituminous.

Here are figures for iron and steel, showing the percentage of increase in the present revised prices over those prevailing in January, 1914, the latter being taken from *The Iron Age*:

Commodity	January, 1914	March, 1919	Increase, per Cent.
Basic iron, gross ton	$12.50	$25.75	106.00
*Black sheets, No. 28	1.87	4.35	132.62
Galvanized sheets, No. 28	2.87	5.70	91.63
Steel bars	1.20	2.35	90.58
Tin plate, base box	3.32	7.00	110.84
*Tank plates	1.20	2.65	120.83
*Nails	1.54	3.25	111.03
Wire rods, gross ton	25.50	52.00	103.92
Billets, 4-in	20.13	38.50	91.26

Two additional comparisons are here given, the 1914 figures being from records of steel concerns in Philadelphia:

*Shapes	1.20	2.45	104.16
*Light rails, gross ton	22.00	54.88	158.54

* Products so marked enter largely into anthracite mining.

As against this, anthracite, all sizes, averaged much less, comparing January, 1914, against March, 1919. The three standard domestic sizes—egg, stove and nut—illustrate this. White ash egg coal cost $3.75 at the mine in January, 1914, and $5.85 in March, 1919, an advance of 56 per cent.; white ash stove, then $4 at the mine, is now $6.10, an advance of 52.50 per cent.; white ash nut, the most popular size of all, which then cost $4.15 at the mine, is now $6.20, a gain of but 49.39 per cent. in a five-year war period.

The percentage of increase, taking all hard coal, including steam sizes, would be much less than the figures shown above. The United States Government, through the Bureau of Labor Statistics, Department of Labor, in the March issue of the *Monthly Labor Review*, gives the advance in all Pennsylvania white ash coal since 1913 as 44 per cent.

Bituminous coal, on the average, has likewise advanced but 44 per cent. over 1913 figures, though of course certain grades advanced beyond that percentage; but coke was not so moderate. Connellsville furnace coke, sold for $1.85 in January, 1914, while it was

quoted at $4 for the week beginning Mar. 24, 1919, a gain of 116.2 per cent.

Not only has coal been beaten out by steel, even using the present steel prices and ignoring the still higher quotations during the last two years or more, but food keeps mounting. Bradstreet's index number, based on the wholesale prices of 31 foodstuffs, was $4.74 for the week ended Mar. 27, 1919, a gain of 9.7 per cent. over the corresponding week last year, and comparing with $4.62 Feb. 27, 1919.

Below are comparisons of food and cotton prices, just before the world war began and as of Mar. 27, 1919. The former figures are from Government reports, and the latter from Bradstreet's:

Commodity	July, 1914	Mar. 27, 1919	Increase, per Cent.
Steers, live	$9.219	$18.70	102.8
Hogs, live	8.769	19.38	121.0
Flour, standard pat	4.594	11.95	160.1
Butter, extra creamery	.27	.5925	119.4
Granulated sugar	.042	.0905	115.4
Cotton, mid. upland	.131	.2830	116.0

Will Put Price Stabilization Program Up to President Wilson

Overshadowing all other matters in official interest during the past week has been the controversy between the Railroad Administration and the Industrial Board of the Department of Commerce over the matter of price stabilization. The discussions have been followed closely by all industries, as the concentration of buying power in the unified administration of all railroads has brought many industries face to face with a most serious situation.

While the whole controversy has been waged around steel rails, it was really the coal operators who brought the question to a head. They declined to enter into any agreement with the Industrial Board until absolute assurance could be given that the Railroad Administration would be a party to the agreement. A number of statements have been issued in the matter, but the one by George N. Peek, the chairman of the Industrial Board, is regarded here as being of unusual interest since it clearly outlines the issues in which so many industries are vitally interested. Mr. Peek's statement, slightly abridged, is as follows:

The Industrial Board was formed to carry out a perfectly defined industrial policy to which the Government, represented by the President, the cabinet and the director general, was fully committed. There is no ambiguity either in the record or in the minds of the people of the United States as to just what that policy is—it is to avoid industrial stagnation pending a return from war to peace prices, to start the wheels of industry, to give employment to labor, to reduce the cost of living, to insure prosperity. Neither is there any ambiguity as to the methods to be employed in accomplishing this end. A scientific study of costs of production is to be made. Upon these studies of costs, prices of basic commodities are to be determined which shall be as low as cost of production will permit, which shall squeeze out all speculative or opportunist profit and upon which industry can commence operations without fear of any considerable drop in the market. This policy and this method are viewed by our people as the first constructive, comprehensive and direct attempt to reduce the cost of living.

To the complete success of this plan, however, there was one absolute essential, that the governmental departments should express the confidence of the Government in the execution of this most important policy. Especially is this true in respect of steel rails, in the buying of which the Government, through its control of the railroads, consumes a very large percentage of the output.

Considering the first of the Director General's reasons for refusing to accept the steel prices—that the Industrial Board has no right to impose a price on the Railroad Administration—the technical prerogative of the Railroad Administration must be and always has been cheerfully conceded by the Industrial Board. But presuming the Government to have been committed to this important industrial policy the board feels that the Railroad Administration is under a powerful, if not a compelling, obligation, either to have the governmental policy abandoned by the same source that announced it and to assume full responsibility for the inevitable effect of such a step, or to support the policy, or to demonstrate that the Industrial Board has failed in its function and that the prices announced by the board are not fair.

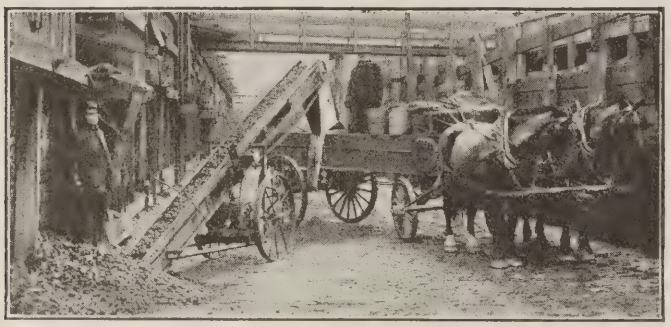
This brings us to the second of the Director General's reasons for his grave action—that "in his opinion" the prices are "too high." The significance of this expression cannot be overlooked.

A representative of the Railroad Administration is a member and a part of the board. Contrary to Mr. Hines' impression, this representative did not maintain that the prices of steel generally were "too high." He finally dissented only on the price of rails. That is not, however, the circumstances of greatest significance, which is that, throughout the discussion, from its earliest word to this latest pronouncement, the figures representing the costs of production were constantly available to the Railroad Administration's representative, and the basis upon which conclusions have been reached has been repeatedly represented to the advisors of the Director General and to Mr. Hines himself. Never have those figures been contested, never have additional or contradictory data been presented, never has the argument of the Railroad Administration been addressed to those figures nor to the conclusions drawn from them by the board.

In fairness to the Railroad Administration it must be admitted that, by using the full effect of its power of monopolistic buying it might secure a price on rails somewhat lower than that announced by the Industrial Board. The figures stand to prove, however, beyond all question, that such a price would be lower than production costs of any but one or two of the most highly organized, powerful, and lowest cost producers. For example, the pre-war price of rails was $30. The increase over pre-war costs of production, for the United States Steel Corporation, in direct labor alone, excluding labor in transportation, is reported by that corporation to be $19.48 per ton. The price approved by the Industrial Board on rails was $47, or $2.48 less than the increase of cost of labor alone would account for.

The inevitable result of the use of the enormous buying power of the Railroad Administration to reduce any price would be to create a situation which would have to met in one of the following ways: (a) Increasing of the prices to the public, (b) throwing all railroad business into a monopoly of powerful producers, (c) reducing wages.

In the opinion of the majority of disinterested men all of these results are highly undesirable and are, of themselves, gravely inimical to industry and to the public welfare. These results alone are, however, of an importance relatively incomparable to the vastly greater harm in the frustration of the industrial policy of the Government and the forced return to the period of commercial and industrial stagnation.



Doubtless the Director General is within his rights in insisting upon his technical prerogative to determine prices for himself, to exercise an arbitrary discretion in making that determination, and to use all the powerful means within his control to obtain the lowest possible prices on iron, steel and coal for railroad consumption. The board insists, however, that in the exercise of that right the Director General must assume full responsibility for all the results of the course he has chosen.

It is not the opinion of the board that governmental organization is such that important policies can be so lightly frustrated. The Railroad Administration's refusal to accept the steel prices puts a temporary check on the work of the board, but before abandoning the vital industrial policy which it represents, the board will see that the whole controversy is submitted to the President for final decision.

New Apparatus and Equipment

Portable Scoop Conveyor Does More Work with Less Manpower

The new type of portable belt conveyor manufactured by the Portable Machinery Co., Inc., of Passaic, N. J., is an improvement over previous designs. The machine is operated either by electric motor or gasoline engine and is known as a scoop conveyor, because the conveying belt receives its material from a scoop that can be forced under or completely buried in the material to

EFFICIENT CONVEYOR FOR HANDLING LOOSE MATERIALS

be conveyed. It will handle coal at the rate of 1 to 1½ tons per minute, depending upon its size.

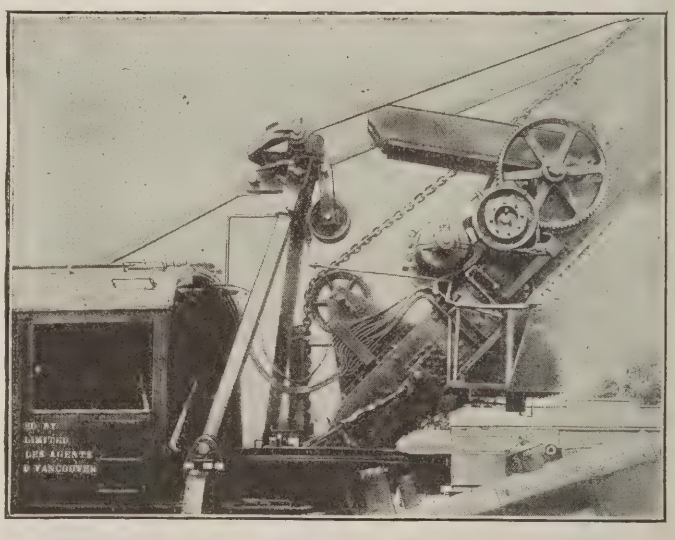
The object sought is to provide a portable machine than can readily and easily be handled by one man for the purpose of loading and unloading, stacking and reclaiming loose materials such as coal, coke, ashes, crushed stone, sand and gravel.

This conveyor has a wide range of application. In the accompanying illustration it is shown handling coal from a pocket to a wagon at a big saving in labor. It will also handle sacks, packages, boxes and various manufactured products. One man with this conveyor, it is claimed, will handle without difficulty loose materials with greater speed than 6 to 12 men without it.

It is highly important under present-day operating conditions to keep trucks moving, save demurrage charges and cut the cost of shoveling. A number of well-known coal concerns are already employing from one to six of these conveyors.

Motor-Driven Shovels and Dragline Equipment for Mine Work

As a means to economy where electric power is available, electrically driven shovels or draglines are used for stripping overburden, mining coal, excavating, dredging, reloading coal and coke, and similar work.



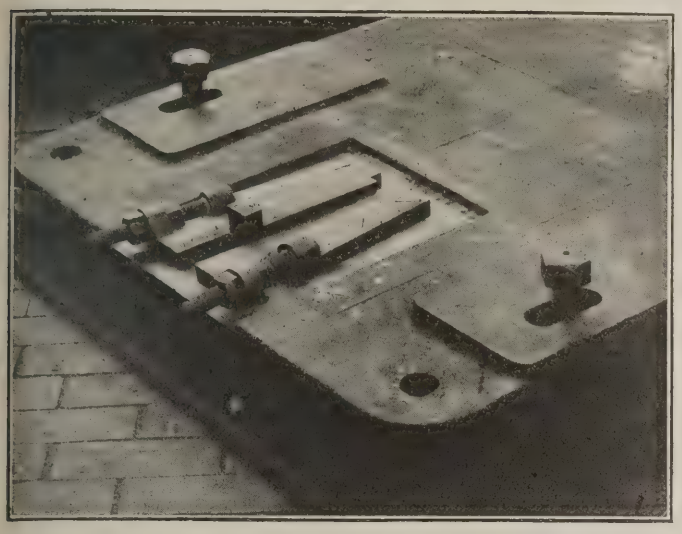
The advantages arising from the use of the electrically driven shovel and dragline are as follows: Lower operating cost, especially when fuels are scarce, expensive or hard to transport; a smaller number of operatives are required; there is no water to supply line to freeze; no boiler or boiler troubles; no standby losses; no smoke; no sparks; no objectionable noises; and more material can be handled.

A complete line of shovel and dragline equipment that meets the especially severe service encountered in such work has been designed by the Westinghouse Electric and Manufacturing Co. Simplicity is one feature of the apparatus tending to give it reliability in operation without skilled and frequent attention.

Both alternating- and direct-current equipments can be furnished. In general, the location of the shovels make alternating-current equipment preferable, because this current can be transformed economically. With the use of alternating-current motors the necessity of converting alternating to direct current is eliminated.

Such motors are of the wound-rotor type capable of exerting powerful effort at the instant needed in the cycle of operation. Each motor is mounted on a heavy frame with a strong shaft and amply large well-supported bearings of the oil-ring type. The rotating part is of small diameter and consequently has a low flywheel effect, which permits rapid starts, stops and reversals. The motors have few wearing parts and require little attention except for an occasional oiling.

The controllers are simple and compact, and are so designed and arranged that the operator can, by manipulating his master switches, cause the shovel to respond to his every wish with facility. By means of



ELECTRICALLY OPERATED SHOVEL REDUCES LABOR COSTS

the protective features of the controllers the shovel or dragline can be operated at its maximum rate without injury to attendants or equipment, and without loss of time. Due to the ease and simplicity of control and the savings in power cost, through the use of the motor-driven shovel and dragline equipment, not only can more material be handled, but this at a lower cost per cubic yard. The standard equipment of the shovel and dragline consists of wound-rotor motors, magnetic contactors, master controller and transformer.

Adjustable Motor Anchorage

For the purpose of adjusting motors of 20 hp. and over upon their bedplates the Adjustable Anchorage Co., of Detroit, Mich., has recently placed upon the market the adjustable anchorage here illustrated. The device is simple, reliable and positive. It is particularly advantageous for motors equipped with magnetic clutches, although it is useful on motor driving belts. Heretofore

ADJUSTABLE ANCHORAGE FOR MOTORS

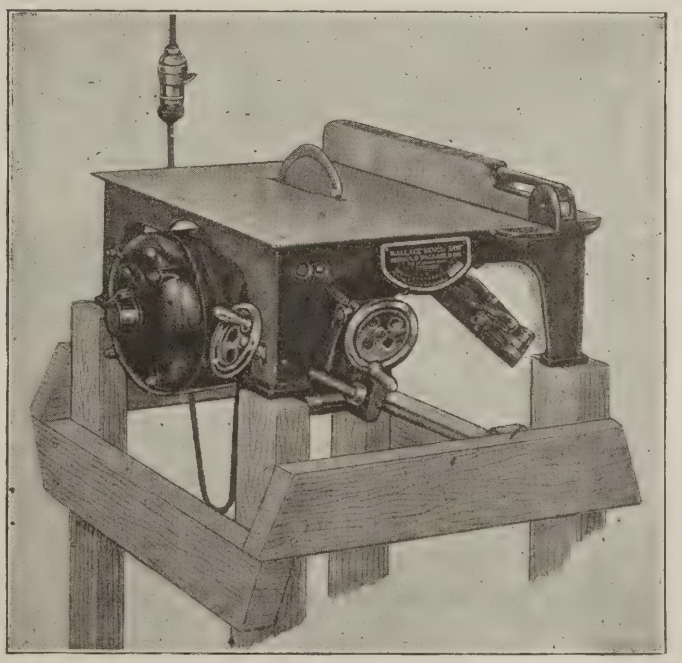
motors have not infrequently been dowelled in place. Any change in location of a motor so positioned is difficult, slow, and often entails injury or destruction to the concrete foundation. With this new device slight changes in the position of the motor may be readily and quickly effected, the only tool necessary being a suitable wrench.

Experiments on a New Pump to Withstand Acidulous Mine Water

Because of the exacting and adverse conditions under which mine pumps are operated, engineers and mining men are manifesting considerable interest in the outcome of certain experiments now being conducted by the Midwest Engine Co., of Indianapolis, Ind., on a pump of new design which is constructed from more resistant metal than is at present employed in mine pump-making.

The new pump will be of the duplex, double-acting, power-driven plunger type, unusually rugged in construction and driven by helical instead of spur gearing. It is designed theoretically to withstand the most severe duty imposed by gritty and acidulous mine water

Builders have long attempted to overcome the rapid deterioration in pumps arising from mine conditions. In the anthracite region especially an unusual amount of sulphuric acid is encountered in the mine water. Under these circumstances the life of the average mine pump is at best short.



In view of this condition the experiments referred to are being conducted to develop a metal of such a composition as to withstand deterioration due to acidulous water. Already a cast iron has been developed that shows a tensile strength as great as that of steel.

With this new pump the designers expect to provide a construction that will stand up against the abrasive effect of gritty and acidulous water and to secure vastly longer pump service than has been the rule with power models.

Handy Portable Saw for Mine Use

A light, portable and relatively cheap circular saw that can be connected to an ordinary lamp circuit, and which should prove a valuable asset in the mine carpenter's shop, is shown in the illustration. The saw is operated by a ½-hp. General Electric motor fitted with ball bearings, and is capable of readily handling any wood up to 2 in. in thickness. In addition, it can be used for grooving lumber of any thickness. This saw should effect a considerable saving on routine work such as the irregular cuts necessary in some of the material going into mine cars and other construction.

A novel feature of the saw is the arrangement for tilting it, together with the motor, at any angle which it may be desired to cut. The saw differs in this respect from most others of this type, which usually tilt the table itself, allowing the saw to remain stationary. One of the chief advantages of this arrangement is that it facilitates cutting long pieces that would have a tendency to slide off the table when this is not horizontal. The exact angle of the cut may be readily fixed

SAW WITH PROTECTING GUARD IN POSITION

by turning the small handwheel. Once set there is no danger of the angle becoming deranged.

In cutting grooves, the saw can also be raised or lowered to cut any depth up to 2 in. This is regulated by a small handwheel like that used for controlling the angle of cut.

The saw shown has the shutter saw guard in position. As the material moves in to the saw, this is slowly moved back by an ingenious device, thus protecting the operator's hands. The device also eliminates the catching of the tail end of the stock in the back of the saw. The tool is manufactured by J. D. Wallace & Co., 1401 W. Jackson Boulevard, Chicago, Ill.

EDITORIALS

Prospect of High and Higher Prices

A CARTOON does not create ideas. It merely expresses the ideas after they have once been formed. It cannot create a point of view, it can only recall and strengthen it. As a hyposulphite of soda solution is only able to make permanent a photographic impression already made, so a cartoon can only serve to permanently fix in the brain a thought already outlined therein.

Likewise, when labor is represented in a cartoon as defending high prices, one is disposed to wonder what is intended. Surely, it will be said, labor is always most querulously objecting to an increase in price. Yet it is the laboring man who is the defender of the high prices he deplores. It is his higher wages that causes prices to be so high. He gets from 80 to 90 per cent. of the product of his toil as wages. Much of the other 10 or 20 per cent. is payment for the use of past construction of labor. So the price of the labor is a very large part, sometimes the whole price of the article produced. High prices inevitably result from high labor costs. They cannot be divorced.

LABOR to CAPITAL: They will have to down me, too, brother, before they take away what is tied up in this poke.

NEARLY 90 PER CENT. OF ALL COMMODITY COSTS ARE FOR LABOR, AND HIGH PRICES CAN NOT COME DOWN UNLESS LABOR CONSENTS

Similarly, labor and capital are so usually considered to be enemies that when they are, in a cartoon, joined as friends we must have them shaking hands as people just introduced or embracing one another as if suddenly convinced of a newfound fraternal relation. All of which is a sign that our thoughts are so contrary to the truth that symbols fail, for symbols cannot be intelligible where the thoughts symbolized are lacking in our brains. So, to use our simile, it is necessary to expose a new plate to which the fixative solution may perhaps be successfully applied later. We must do our arguing first and look for the cartoon to tell the story pointedly later. It is needless to emphasize that the cost of labor will remain up, for the unions will not let it come down. Whoever would reduce prices must take up his battle with labor.

Business men in general know that their own prices are on a bedrock except insofar as they threaten even to rise still higher as the outcome of a strike. They, themselves, refuse to sell at any other than the price they have set, for that price is such that only by obtaining it can they make both ends meet. Yet they are ready to believe that all other men are different from themselves. They expect every moment that the man from whom they buy will divide his prices almost in two and get back to a pre-war basis. They forget that their own prices are, and must continue to be, as greatly inflated as his—till the price of labor goes down, a time that will never arrive.

Even the interest-on-investment account is more or less based on labor, though the interest now charged may even be double that formerly provided. A factory built and equipped ten years ago cost less that would another of like character built today. But as the old factory competes with the new one, its value is bound to increase, and its owner can charge an apparent profit, for indeed it is only apparent. It may be shown that it is for the public advantage for him to do so, nor is it an unethical act so to do.

Let us take up in order the contentions for this argument. With higher prices for construction, building will not become active till higher book profits on completed buildings or, what is the same, higher rents become general. That may be readily conceded. The public wants more building, and what increases the amount of building helps the public.

As for the ethics of higher charges, it may well be shown that the old building was erected by the dollars of, say, 1909, and the rent and profit is collected in the depreciated dollars of 1919. If a building cost $100,000 in 1909, 10 per cent. for interest, repairs and depreciation would amount to $10,000. Today the receipts on the investment would be paid not in real dollars, but in 60c. dollars, which would not bring the owners as much goods or make as much repairs or replace as much of the building as in 1909. The return would be equivalent to $6000 in the currency of the year of construction.

On the whole then, labor, past or present, is the cause of almost all elements of cost and therefore the base of all price. The element of past labor has not yet got in its finished work. In a short while, however, it will do so everywhere as will be shown by a general increase in rents. When it does complete its mysterious work there will be a further rise in costs of all articles, but the increase in cost due to the raise in wages of the body of workmen to whom the war has brought a salary not adequate to the demands of a new cost of living will be a still more important factor. Perhaps, also, further wage increases, unjustly granted to bulldozing unions who want all for their little group of workingmen, will be an even greater cause of an ever-increased cost of everything.

When the governors and mayors met recently they elected to discuss the shortcomings of the national government and of business, whereas little has been more disturbing than the action of the governors and mayors themselves; and they had plenty of room for searchings of heart and purpose. More municipal and state construction, it would seem, went on during the war than is going on now, though everybody agreed that such work hampered hostilities. But the governors and the mayors utterly failed to see their obligations and avoided the issue. The public wants the business men to accept all the risks of resumption, and the members of the conference are unwilling to urge upon the people the commencement of any construction work for which they do not make a spontaneous demand.

Adequate Ventilation and Big Tonnage

ONLY by good ventilation can men put out an adequate tonnage. The air should be so readily cleared that the miner is able to return to his place within ten minutes after he has fired his shot. However, it is hard to make the average operator realize this; he has been so accustomed to see the miner wait on the entry for the clearing of the air. We have all seen that worthy many a time, with his coat thrown, like the sheepskin of Hercules, over his shoulders watching the slowly eddying currents taking the air out of the working place or viewing them with disgust when they actually turned around and carried the smoke back to the scene of his operations.

The miner also seems unable to comprehend that he is entitled to such ventilation, so long has he done without it and so adaptably has he trained himself to fill in the interim by taking a piece from his pail and visiting his neighbor's place and so ready is he to go home when his afternoon shots are fired. In some poorly ventilated mines a man is almost suffocated if he stays an hour after the round of evening shots, and as a result each man races with his fellow to be the first to fire.

With our tonnage system good ventilation, if there is any, must be provided by the operator and cashed in by the employee, so the air supply rarely gets up to the level of the law and often falls below it. The metal-mine operator is not waiting for the law. He is going ahead of it, for running his mines by the day, he cashes in on the improvement in production resulting from his expenditures. In less than three years certain metal mines in the Southwest increased their production per man 150 per cent. Whereas, before the improvements, the men mined about 2.8 tons per shift, after the changes were made they mined about 7 tons. The cost of mining dropped from $1.63 to about 82c. per ton.

Of course, there were many causes of variation in product and cost, some of which worked doubtless in the opposite direction to the tendencies shown; but nevertheless the credit for the improvement has been largely and rightly, laid to better ventilation. Undoubtedly these mines were warm and disinclination to work in humid and warm air had as much to do with the improvement as the ability afforded the mucker of making a speedy return to work after shooting. But to show that work was being hampered by the lack of air, it may be said that 110 million cubic feet of compressed air were used before the improvements and barely 80 million after them. The air was evidently being used to clear the places of smoke. The best way to prevent this waste of compressed air where compressed air is supplied is to afford a better means of allaying the nuisance arising from bad air. This loss at any rate, where it is encountered, is a loss to the operator and not to the employee; and insofar as good ventilation will prevent it the successful meeting of the difficulty will prove profitable to the operator.

It is estimated that at least $500,000,000 in interest and dividends will be due yearly to the United States from foreign debtors. Unless our widely heralded goodwill and warm friendship for European countries is mere talk, we should not expect these foreign nations to pay their debts to us in cash here. Even if such a plan were feasible it would lose for us, not only our leading position, but also deprive us eventually of our foreign trade. Consequently, if we are not to be paid in gold over here, we must use the foreign money we are to get over there to make foreign reinvestments. America can no longer live in isolated fashion. We must improve and run foreign factories, build foreign railroads, send agents to buy goods direct at production points and establish banks throughout the world so as to keep the American dollar at full value.

Our National Honor Engaged

THIS country made good in its war. Germany had sneered at us "money-grubbing Yankees." She had proclaimed we would not fight; that we could not fight. Having seen raised the army she said couldn't be raised, she declared it never could be transported overseas. It was transported overseas. Men of that army broke the famous Hindenburg line, and went through the Argonne, which had been considered impregnable.

More than that, the whole country stood behind its fighters. We shifted the entire industrial system of the land to war purposes. By the labor of those men who were not considered essential to the country's military purpose and the devoted efforts of loyal women, we heaped up a tremendous supply of munitions and war materials which, quite as much as the valor of our men, contributed to the early ending of the war. We bought issue after issue of Liberty Bonds, so that the Government might have money for its war purposes, oversubscribing every loan so that there might be no mistake, either here or in Germany, about our deadly earnestness in the great cause.

We have a right to a great pride in our soldiers and a great satisfaction that we backed them so loyally. But pride in what has been won must not blind us to the fact that there remains a further task. That is the paying up of the war's bills. Our victorious soldiers are returning. They have done their work. We shall not have completed ours until the Victory Liberty Loan, which is to settle the debts, has been subscribed.

Our national honor is engaged in this, just as it was in the military phase of the war. The United States, a leader in the great task of helping the world to peace, prosperity and freedom, must not be a debtor at home. It is an obligation resting on each of us to see to it that this final undertaking of the war is accomplished. We cannot—must not—quit until the success of the Victory Liberty Loan may be ranked with the success of our fighting men.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Sanity seems to be reasserting itself in the mine workers' ranks. Steady work will probably remove most of the fads which have misled even the best of them. The very leaders who have called loudly for changes will cease their clamor in the face of a steady demand for coal. The anthracite districts are already working more steadily and in a short while the bituminous region will also show the tonic effect of steady work.

The operators sympathize with the men who have been harried to work hard and then have been told that they have mined so much coal that they must lie idle till the fuel they labored so hard to produce is entirely exhausted. The mine owners also realize that closing mines is a form of eviction, an act of efficiency and of prudence, perhaps, but one not without its painful sides. They know that permitting the miners to work while the day men are idle reduces the hours and pay of the day men. But prices are low and conditions are difficult. The companies cannot run steadily if people will not buy, and they can't get out coal economically and pay their way if they hire men more hours than the work to be performed demands.

Steady demand will correct all the difficulties, and the market should try and provide it. Above all the Government should do its utmost to relieve the situation. It should not, as has the Railroad Administration, try to lock out the mines and so make it compulsory that a lower wage be paid mine workers and a lower price be charged for coal. The mine workers are surely entitled to their present pay and should not yield to the Railroad Administration in its apparent determination to seek from the coal industry the money whereby to pay its own men the increases in wages just granted.

Only Fair Price Will Secure Fair Wage

Governor Sproul's action in sustaining the anthracite operators in their contemplated readjustment of prices May 1, when a 10-cent increase per ton per month is to become effective for five months, is warmly praised by Thomas Kennedy, president of the United Mine Workers of the Seventh District.

"The statement of Governor Sproul," he said, "shows a broad and intelligent understanding of the anthracite situation. I am more than pleased when he says we are all anxious that the present wage scale in the anthracite region be maintained. That coming from the chief executive of the state will, in my opinion, silence those who had hoped to reduce wages and will do much to stabilize the anthracite trade."

Anthracite Labor Makes New Rules

Circulars warning all miners to refrain from cutting or loading coal on idle days will be sent to all locals in the three anthracite districts immediately. This action has been decided upon by the tri-district officials. Only necessary repair work about the mines will be permitted on days when the mines are not being operated.

The board favors a 70 per cent. compensation pay, starting the second day after the injury, instead of the 50 per cent. now allowed.

The board is arranging for a tri-district convention to be held in September to frame the new demands of the miners, which are to be presented to the operators at the expiration of the present scale, which expires Apr. 1, 1920.

West Virginia Celebrates Eight-Hour Day

The celebration of the second anniversary of the establishment of an eight-hour day for the miners of West Virginia was observed at Rivesville, W. Va., on Apr. 1 and was featured by an address by President F. C. Keeney of District 17, in which he attacked Bolshevism in all its aspects. He said in part:

"I sent out a circular letter some weeks ago, which I desire to explain at this time. The United Mine Workers of America have done more for the miners than any other organization ever can hope to and it objects to the radical policies of the Industrial Workers of the World and other similar institutions, the success of which would bring about the destruction of the union.

"The rules of the United Mine Workers stand for the expulsion of members who cherish such ideas as Bolshevism and if the local does not have spine enough to expel them I will go there and expel them myself. Much evil is cloaked in Bolshevism. Perhaps you don't understand Bolshevism. Neither do I, but I am opposed to supporting any such radical movements."

The opening part of Mr. Keeney's address dealt with the history of the eight-hour day. It was started in 1898 in Illinois, where the miners had to submit to a cut in wages in order to establish it. The idea, President Keeley stated, was one of years' standing, having been advocated by John Synie, of Pottsville, Penn., fifty years ago—shortly after the Civil War. His own followers persecuted him, although he was an ardent believer in the rights of the working man and a "real labor leader," as Mr. Keeney put it. He recalled how Synie went to Indianapolis from Pottsville, Penn., on foot to attend conventions, which, in all, probably represented only 2000 or 3000 miners.

Forty-eight years afterward on the same spot—Pottsville, Penn.—John P. White, international president of the United Mine Workers of America, inaugurated the eight-hour day.

The eight-hour day did not make its appearance in the State of West Virginia until Apr. 1, 1917, when Mr. Keeney inaugurated it after a tenure of office of only a few months. Last year the Kanawha Coal Operators' Association with operations in the southern part of the state sanctioned the day and upon the letting down of the non-union bars in the Fairmont field it was celebrated there this year. The eight-hour day leaves the foreigner with two more hours in which to acquire a knowledge of our language and laws. He should not fail to take advantage of this opportunity. Nor is he the only one who should use this larger waking rest period with profit. Even American workmen should seek in it an opportunity to add to the training already received in the public schools.

Should Binder Figure in Coal Thickness?

It may require the services of an expert to settle a dispute between the miners and operators of the Elkins field as to when "coal" is coal or when "coal" is not coal, the controversy having arisen in connection with an agreement covering the mining of coal in the Pittsburgh bed.

The agreement calls for the mining of coal in that vein of 5 ft. or more in height or thickness. The question has now arisen whether the "binder" is included in that measurement. Miners insist that under the agreement it should be included. The operators take the position that it includes only 5 ft. of actual coal and excludes the binder. While no agreement has so far been reached at the one conference so far held, it is felt that it will be possible to reach an agreement when the parties to the controversy meet a second time.

Coal-Mine Labor the World Around

On Apr. 1, Frank S. Hayes, the president of the United Mine Workers, stated that he and Robert H. Harlin, of Seattle, would go to Paris to urge upon President Wilson personally the need and desire of the mine workers for the development of the export coal business of the United States. The leaders expect to visit Mr. Smillie, in Great Britain, and to see other British labor leaders, who will perhaps, convince them that the British are seeking the same end and that the natural ambitions of the Allies —no, that is not the correct word—"Associates"—are conflicting.

The W. J. Rainey Coke Co., in the Connellsville region, as related in the issue of Apr. 3, has had a strike because of its determination no longer to give free powder to miners. The mines have resumed operation. The product of the ovens of this company used to go in part to the Pittsburgh Steel Co. That corporation has acquired the W. Harry Brown properties; and the ovens formerly belonging to that operator, which were shut down, are now being put to use again. It is natural to wonder if the W. J. Rainey operation will be as active as in the past, now that this rearrangement of ownership has been effected.

The Ohio mine workers have been protesting through President Hayes, of their union, against the discrimination in purchasing exercised by the railroads. Director Hines has replied that the matter is left to the determination of the various railroads, which buy in accord with their needs.

Limit to Working Less and Doing More

In Alabama, President J. R. Kennamer, of District No. 20, has declared in favor of the six-hour day for mine workers on the ground that the air is impure and cannot be endured for a full eight hours. It is regrettable, if that is the case, though it may be true in some of the smaller operations. There is surely no need for it, and in up-to-date mines the air is unusually fresh and invigorating, far more bracing and life-preserving in summer than the stuffy climate of the oversoil.

Mr. Kennamer alleges that it has been proved that more has been achieved in the mines in eight hours of work than can be accomplished in ten. Everyone awaits his proof, but perhaps it was true in Alabama where the change in the duration of the day was concurrent with the war excitement. Under such circumstances the larger working efficiency might well be ascribed to the enthusiasm resulting from the war rather than to the working of an economic law.

It is surely permissible to ask him to "quote chapter and verse" for his statement. True, Paul F. Brissenden, of the Bureau of Labor, did in 1917 try to show that shorter hours had increased production in the anthracite region, but his figures did not prove it as was shown editorially in the issue of *Coal Age* of Sept. 8 of that year. His figures showed just the reverse.

But if the figures showed just what Brissenden said they did, there is no reason to suppose that, taking them as a basis, a man would do more in six hours than in eight; or, for that matter, in four hours than in six or in two hours than in four. To carry the reduction to the limits of absurdity, we might declare that if he didn't do any work at all he would achieve more than if he worked for two hours every day. Kennamer is the "devil's advocate" when he thus talks to his Alabama audiences. He means well, doubtless, but the effect is equally mischievous whether his purpose is well or ill.

Want Short Day if Competition Permits

From Lethbridge, British Columbia, comes a perfectly sane statement on the six-hour day from President Christopher: "Regarding the six-hour proposition: We are still in favor of this, but how many of us really believe that it is possible to bring this about in this district while the other coal fields competing with this district in the same markets are working from eight to ten hours a day? It is at present a matter of competition in the markets, and no one, no matter how desirous of bringing about a six-hour day, can gainsay the fact."

This, however, is not enough. Competition is not the main cause for a failure to reduce the hours of work. Canada can reduce laboring hours as well as the United States when the mine workers of the United States so determine and the public is willing. But neither ought to reduce hours till they are about to be reduced in other industries, and until the mine workers and others are willing to sustain the inevitable loss that the shorter day entails they should remember that shorter hours mean less product; that is, less goods created and less goods to divide. The wage could be made the same for the shorter working period, but that would do no good, for six hours' work can give but six hours' product, and there then will be but six hours' product to divide. If we fail to bake our cake it is sure we shall never eat it.

At Thurber, Tex., all the coal-mine operators of the Texas & Pacific Coal and Oil Co., numbering about 300, went on strike the week before last, remaining out for several days pending a settlement of their grievance which arose over the wage contract. The matter was finally settled through the efforts of the officials of the miners' union.

British Workmen Accept Sankey Wage Plan

British mine workers seem to have been satisfied with the Sankey decision. They are disposed to believe that it concedes almost all they could possibly hope for. Even the Welsh mine workers voted 6 to 1 in its favor when the question of accepting or rejecting it was submitted to their vote on Apr. 11. No mine workers in Great Britain are more disposed to make large demands than the men in the South Wales field. Now that even they are satisfied the matter is disposed of for a while till a period of agitation has managed to create a new discontent with the award. The mine leaders must yearly give an account of their stewardship. Larger pay, shorter hours, democratic control of industry, nationalization or something must be sought, otherwise the mine workers will think their leaders remiss.

In Germany many strikes have recently occurred. On Mar. 29, 30,000 men were on strike in the mines around Essen, thirty shafts being closed down. In Witten and Dortmund, and indeed elsewhere, the trouble seems to have a Sparticide origin, the demands made including one for the withdrawal of Government troops. An increase in wage of 25 per cent. was asked, also additional bonuses and the six-hour day.

A meeting of delegates of the revolutionary mine workers representing 195 mines voted at a meeting in Essen that they would strike on Apr. 1 and discontinue work till their demands were fully granted. The men wanted all political prisoners released, the disarmament of the police in the mining districts, and payment by the Nation for every day the men had been on strike. They sent a message to the governing council at Budapest containing brotherly greetings and declaring that they were inspired by the victory of their Hungarian comrades over "the accursed class." They promised that they would fight with their Hungarian and Russian brothers with all their means to compel the establishment of a Socialist Soviet government.

All German Miners Seek Changed Conditions

The mine workers mentioned are classified usually as of the Ruhr Valley. When they struck, the revolutionary mine workers of Central Germany and Silesia declared themselves as sympathetic and made demands on their own behalf, declaring that if these demands were not granted by Apr. 9 they would cease even emergency work. Thus the mines would be flooded. They condemned all those who had joined the army in response to Herr Noske's appeal. At that time, Apr. 6, there were 345,000 men on strike, and 215 mines were thus thrown idle.

The revolutionists were using intimidation to compel every one to enter their ranks. A Council of Nine, thoroughly unrepresentative of the miners, has been formed. It consists solely of Sparticides and communists. The revolutionists declare that they will allow none other than this *ex parte* committee to represent the mine workers in handling matters with the government.

At the same date the men at Dortmund were reported going back to work. Nevertheless the strike was growing larger hour by hour and it was steadily embracing more occupations. Since then conditions have been becoming increasingly chaotic.

To Have More Money

All we need in order to have more money is more printing presses. But what we need is not more money but more goods; and how will we get goods unless we work for them?

There was a King named Midas who, the Fable says, turned everything he touched to gold. He nearly starved to death. The unions may so arrange it that every way a workingman may look he will see wages, but if he doesn't work and if other men don't work, he will starve to death like Midas.

We can't let "George do it." We must all work a reasonable length of time each day or there will be nothing else but wages; and it is a fact wages never have and never will make good eating. What we need to worry about is not how to get more money, but how to make more goods.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Certification and Safety

Letter No. 2—I was deeply impressed with the able remarks of James Touhey, *Coal Age*, Feb. 20, p. 374, in which he criticises the attitude of the members who attended a recent meeting of the Coal Mining Institute of America, at Pittsburgh, Penn., when one of the questions discussed was "Has the law permitting the employment of uncertified officials in coal mines been detrimental to the efficient and safe operation of the mines?"

Mr. Touhey states that what appeals to him, in this connection, is the fact that "an intelligent body of men meeting to discuss questions of vital interest to their calling should not arrive at some definite conclusion." He admits that the holding of a certificate is not a guarantee of the competency of the man. The same was also admitted by those who took part in the discussion of this question, at the Pittsburgh meeting, it being claimed that the certificate was merely "an index" of the man's competency.

While I deem it unwise to criticise the actions of examining boards and other intelligent bodies, such as I have witnessed at Owens College, Manchester, and Watson's College, Edinborough, especially when one holds, as I do, mine foremen's certificates granted me, both in Great Britain and in the United States; yet, to my mind, there is a great lack of efficiency in the examining boards in both countries, in respect to the practical experience that should be required of men authorized to examine candidates and grant certificates of competency for mine foremanship.

EXPERIENCE REQUIRED OF MINE FOREMEN

The Coal-Mines Regulation Act of Great Britain and the Bituminous Mine Law of Pennsylvania each require that the candidate for a mine foreman's certificate shall have had five years' practical experience in mines. In my judgment, this is where the root of the trouble lies. The man with five years' experience is hardly competent to take charge of a coal mine. He should have at least nine years of practice in the general routine of work underground. This should include besides the mining of coal with pick and by machinery, methods of timbering, pumping, drainage, tracklaying, mule driving and a knowledge of and acquaintance with electric installations.

The nine years' experience, in such general work as I have just named, should include five years' experience in shotfiring and firebossing. He should have, moreover, a thorough knowledge of and acquaintance with the mining laws of the state, before I would consider him a fit candidate for the office.

The work of mining coal is a perilous undertaking, and the man in charge should be possessed of the cream of knowledge, in respect to both the theory and the practice of coal mining. To my mind, there is no question relating to coal mining that is as important as that of the certification of mine foremen.

The statement to which I have referred that, "a certificate of competency is merely an index to a man's ability to act as foreman of a mine," makes it appear that the Board of Examiners who grant such certificates are mere indexes themselves. If this is true, it is high time, in this 20th century, that the coal industry of this country should be represented by boards of examiners who are able to issue certificates of competency that are something more than indexes to a man's ability.

I fully agree with the mine inspector, who, speaking at the Pittsburgh meeting, is reported, *Coal Age*, Dec. 12, p. 1081, to have remarked that "the operator who allows an uncertificated man in an authoritative position in his mine is a criminal." Let me say that the men who make and those who sign the laws that make this condition possible are likewise criminal.

In closing, allow me to appeal to the mine inspectors of the different states who read *Coal Age*, to take part in this discussion, which is intended to show the relation of the uncertification of mine officials to safety in our mines. State mine inspectors are the intelligent heads, generally, of the state boards of examiners. It is to be regretted that so many state mine inspectors are willing to discuss these questions only when they are no longer in office. This appears to me a mystery.

Springfield, Ill. JAMES N. RODDIE.

Engine-Plane Haulage

Letter No. 3—The proposition presented in the inquiry, *Coal Age*, Feb. 6, p. 293, is an interesting one. It appears that engine-plane haulage had been in use on the 400-ft. incline, which is said to have a grade of 25 per cent. At the foot of this incline, the road leads into the mine and has a uniform grade of 1½ per cent., for a distance of 1000 ft., to the side track where the trips are made up to be hauled to the surface.

Three car trips, weighing $3 \times 5000 = 15{,}000$ lb. were hauled up the incline from the mine entrance to the tipple. It is stated that each empty car weighs 1500 lb., while the weight of a loaded car is 5000 lb., making the weight of coal hauled in each car $5000 - 1500 = 3500$ lb. It is now desired to continue this engine-plane haul to the side track 1000 ft. back in the mine.

The fall of the 400-ft. incline is $400 \times 0.25 = 100$ ft., while the fall of the mine road, in 1000 ft., is $1000 \times 0.015 = 15$ ft., which makes the total fall from the tipple to the side track 115 ft. Now, if it was practicable to build a uniform grade from the tipple to the side track, the total length of such grade would be 1400 ft., and its inclination $(115 \times 100) \div 1400 =$ say 8 per cent., which would make a good engine-plane haulage.

But, assuming that it is not practicable to build a uniform grade, I will estimate on an average speed of hauling of, say 8 mi. per hour, for the empty trip running into the mine, and 10 mi. per hour, for the returning trip when on the mine road, and 3 mi. per

hour on the incline. I will allow 2 min., at each end, for changing ropes and starting the trips.

A speed of 8 mi. per hour is $(8 \times 5280) \div 60 = 704$ ft. per min., which makes the time required for the empty trip to run into the mine, $1400 \div 704 =$ say 2 min., and adding 2 min. more for changing ropes and starting the trip gives a total of 4 min. for the empty trip. Likewise, a speed of 10 mi. per hour is 880 ft. per min, and a speed of 8 mi. per hour, 264 ft. per min. The total time for the loaded trip, then, including the 2 min. for changing ropes and starting, is $(1000 \div 880) + (400 \div 264) + 2 =$ say 5 minutes.

On this basis, the time of making one round trip is 9 min., or, allowing for some delay, we will say 10 min. per round trip. Then, hauling 8 hours a day, the number of trips is $(8 \times 60) \div 10 = 48$ trips; and, for an output of 500 tons per day, the weight of coal hauled per trip is $500 \div 48 =$ say $10\frac{1}{2}$ tons. But, since each car has a capacity of 3500 lb., the number of cars that would have to be hauled in each trip is $(10.5 \times 2000) \div 3500 = 6$ cars.

The question at once arises as to whether the cars in use are strong enough and whether the drawbars will stand the pull of a 6-car trip on a 25 per cent. incline. If the car is too weak for this pull, it may be possible to haul two 3-car trips on the incline, while one 6-car trip is hauled on the mine road.

Calculating the Horsepower Required

In regard to the horsepower of the engine required for this haulage, I would not care to estimate on a higher speed than 10 mi. per hour on the mine road and 3 mi. per hour on the incline. The greatest load on the engine will occur when the trip is at the foot of the incline and has started up the grade. Assuming a 6-car trip weighing $6 \times 5000 = 30{,}000$ lb., and adding 300 lb. for the weight of the rope on the incline, the total weight hauled is 30,300 pounds.

Estimating the grade on the pitch distance, the sine of a 25 per cent. grade is 0.25 and the cosine 0.968. Then, taking the track resistance as 20 lb. per ton, the load on the engine when the trip is near the foot of the incline is

$$L = 30{,}300\left(0.25 + \frac{0.968}{100}\right) = 7868\ lb.$$

Then, allowing an efficiency of the engine of, say 80 per cent., the required horsepower when hauling at a speed of 264 ft. per min. is

$$H = \frac{7868 \times 264}{0.80 \times 33{,}000} = say\ 80\ hp.$$

When a loaded trip is starting from the side track in the mine the horsepower exerted by the engine must be calculated for a speed of 880 ft. per min., and a total load, including the weight of 1400 ft. of rope, or say 31,050 lb. In this case, the sine of the grade angle is 0.015 and the cosine 0.999. The load on the rope is then

$$L = 31{,}050\left(0.015 + \frac{0.999}{100}\right) = say\ 500\ lb.$$

The horsepower developed when hauling this load at a speed of 880 ft. per min. is

$$H = \frac{500 \times 880}{0.80 \times 33{,}000} = 16\tfrac{2}{3}\ hp.$$

This calculation may enable us to make some modification, in respect to time allowances and speed, that would reduce the required horsepower on the incline. However, it is always wise to have a good margin of engine power to offset any unforeseen delays or occurrences that are liable to happen in mine haulage. The size or dimensions of the engine required will depend on the steam pressure available.

Linton, Ind.

Drawing Pillars in Machine Mining

Letter No. 13—Referring to the letter of D. F. M., *Coal Age*, Feb. 27, p. 415, regarding the drawing of pillars with machines, I was glad to see that he made clear, in that letter, how these pillars should be attacked, namely, on the side opposite to the falls. I have, myself, had considerable experience in cutting pillars with a Sullivan CE7 machine; and, also, with a Goodman shortwall machine. To attack the pillars on the side nearest the falls, as indicated in a previous letter, would surely result in a considerable loss of pillar coal and run the risk of losing a machine.

As D. F. M. has shown, the plan he describes can be adapted either to the retreating or the advancing method of mining, and rooms can be driven off one or both entries of a pair of headings. However, in order to keep the straight rib and the track next to it, on the opposite side of the pillar from the falls, it is necessary to always widen out the rooms in the direction in which the new rooms are being turned, or the direction in which the work is proceeding.

For example, in the retreating system, the headings are driven to the line or boundary and the first rooms are started at the inby end. In that case the rooms should all be widened out toward the main heading, leaving the straight rib and track on the side of the room toward the boundary.

Manner of Widening Rooms Explained in Detail

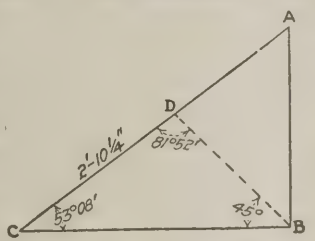
Assuming the butt headings are driven to the left of the main headings and explaining more in detail, rooms driven off the first left entry when retreating must be widened to the left, while those driven off the second left entry must be widened to the right. This will always keep the track on the opposite side of the pillar from the falls and enable the machines to work on that side when cutting out the pillar.

On the other hand, in the advancing system of mining, the first rooms are started a short distance from the mouth of the cross-entries and widened out inby, as shown by the plan given by D. F. M., in his letter, page 415, to which I have referred. In this case, rooms driven off the first left entry must be widened out to the right, while those driven off the second left entry are widened to the left.

Again, if the butt entries are driven to the right, as shown in the figure on page 145, the rooms driven off the first right entry must be widened to the left, and those driven off the second right entry must be widened to the right. In each and all of these cases, the straight rib and track must be kept on the opposite side of the pillar from the falls to enable the pillars to be attacked with safety on that side.

Undoubtedly, the retreating plan would give better results, in respect to the complete recovery of the coal, and there would be less liability to squeeze. But, if the roof is not too strong and will break within a reasonable space after the pillar and standing timber have been removed, it will be more economical to adopt the advancing system.

In the case cited in this inquiry, let me suggest that the rooms should not be driven more than 20 ft. wide, nor have a greater depth than 250 ft., especially if wooden rails are used in the rooms, as it will be difficult to get men to push cars a greater distance than this over wood rails. The pillars should be not less than 16 or 18 ft. thick between the rooms.



All entries should be driven on 60-ft. centers and protected by 40-ft. room stumps. Track should be laid on one side of the room, and three good posts should be set for each 6-ft. cut made in the room. In drawing back the ribs, the three cuts the machine makes can easily be loaded without having to lay a switch in the crosscut.

DANIEL F. SMITH.

Wellsburg, W. Va.

Turning Rooms Without Sights

Letter No. 1—Kindly permit me to refer to the idea presented by Ostel Bullock in *Coal Age*, Feb. 13, p. 306, and to say that his suggestion of a device for turning rooms at a right angle with the entry, before the permanent sights are set up, is a good one, and can be used to good advantage when turning rooms off a straight piece of entry, but cannot be employed as well where the entry is crooked.

THE RIGHT TRIANGLE

I want to draw attention, however, to an evident error in his statement that the same method can be employed when the rooms are to be driven at an angle of 45 deg. with the entry. In that case, Mr. Bullock says, "It is only necessary to sight from the same point on the entry to a point at the center of the 5-ft. string.

The device Mr. Bullock suggests consists of three small rings connected together by three strings whose lengths are 3, 4 and 5 ft., respectively, as indicated in the accompanying figure. As he has stated, this device forms a right angle at the intersection of the 3-ft. and 4-ft. strings. But, a line drawn from that intersection to the center of the 5-ft. string will not make an angle of 45 deg. with the 4-ft. string, which is in line with the entry.

Referring to the figure, let *ABC* represent the device, right-angled at *B*, and draw *BD* making the angle *CBD* equal to 45 deg. Evidently, sin *BCD* = 4 ÷ 5 = 0.8; and the angle *BCD* is 53° 08′. Then, the angle *BDC* is 180° — (45° + 53° 08′) = 81° 52′.

Then, since the ratio of the sides of any triangle is equal to the ratio of the sines of the opposite angle, we have,

$$\frac{CD}{CB} = \frac{CD}{4} = \frac{\sin 45^\circ}{\sin 81^\circ 52'} = \frac{0.70711}{0.99} = 0.714$$

Therefore, $CD = 4 \times 0.714 = 2.86$ ft.; or 2 ft. 10¼ in. Hence, *BD* is the sight line for rooms turned at an angle of 45 deg. with the center line of the entry; and the point *D* is, therefore, 4¼ in. beyond the center of the 5-ft. string.

E. P. HUMPHREY.

Upper Lehigh, Penn.

Letter No. 2—On reading a recent issue of *Coal Age* (Feb. 13) my attention was attracted to a short article by Ostel Bullock (p. 306), describing a method that can be employed where it is desired to turn rooms at an angle of 90 deg. with the entry, without first setting up sights.

The device Mr. Bullock describes, being three rings joined by strings 3, 4 and 5 ft., respectively, will certainly give him a right angle. However, he makes a serious mistake when he says a 45 deg. line drawn through the right angle would bisect the 5-ft. string.

In order to obtain a 45 deg. angle the right angle must be bisected and the bisecting line will not strike the center of the 5-ft. string. A line drawn from the right angle to the center of that string would divide the right angle into two angles of about 53 and 37 deg., respectively, instead of bisecting that angle.

Let me suggest, also, if a mine foreman should attempt to bisect the right angle by drawing a line on the roof of the entry to indicate the direction of the 45 deg. room, he could as well draw a line perpendicular to the center line of the entry to indicate the direction of a room driven square with that entry.

JOHN WALLS, SR.

Porter, Ala.

Payment for Yardage and Deadwork

Letter No. 1—Every coal mine has its difficulties and these vary with the conditions existing in the seam and adjacent strata. Mining the coal, in some seams, is accompanied with no end of expense, while comparatively little or no expense attaches to the same undertaking in other seams, beyond the paying for yardage in driving the entries and turning rooms.

Referring to the case presented by G. Stern, *Coal Age*, Mar. 6, p. 464, where the thickness of the coal is said to vary from 3½ to 4 ft., the seam being overlaid with from 4 to 10 in. of slate, above which is 6 or 8 in. more of coal, let me say that the mining of this coal without incurring a burdensome expense will require care and watchfulness.

I may assume that there is a total thickness of, say 52 in. of coal on the average, which with about 8 in. of slate parting makes the entire thickness of the seam 60 in. This seam has, therefore, (8 × 100) ÷ 60 = 13⅓ per cent. of refuse, which will give no end of trouble, unless some means are adopted to keep the coal clean and avoid the loading of refuse. This will require strict regulations in regard to cleaning the coal at the working face.

MISCHIEF OF A FEW CARELESS LOADERS

Every practical mining man knows that, in working a seam of coal of this character, it will take but a few working places sending out impurities with the coal to lower the quality of the output of the mine and injure its market value. On the other hand, if the coal must be cleaned after reaching the surface, this will add to the cost of production, besides restricting the output of the mine.

Compare, for a moment, the working of such a seam as is here mentioned with that of a good seam of coal of the same thickness but containing no refuse that must be separated from the market product. It is evident that the miners working such a seam have a great advantage over their fellows employed in the seam first mentioned. Let a miner have a few inches of refuse to handle and be given to understand that it must not be loaded with the coal, it is clear he will then be entitled to some compensation for handling this dirt that brings him no revenue.

As an illustration, let us assume that the weight of coal is 80 lb. per cu.ft., or 2000 ÷ 80 = 25 cu.ft. per ton of coal in place. Now, suppose a miner is driving an entry 10 ft. wide in a 5-ft. seam. The cubic contents of this seam for each yard driven is 5 × 10 × 3 = 150 cu.ft., and the weight of the coal, per yard, is 150 ÷ 25 = 6 tons. Assuming 13⅓ per cent. of refuse, as previously calculated, the loss in coal when driving such a place would be 0.13⅓ × 6 = 0.8 ton. If the price of mining is 90c. per ton, this would mean a loss of 90 × 0.8 = 72c.

Calculating this loss, per inch of thickness of slate, having assumed an average thickness of 8 in., gives 72 ÷ 8 = 9c. of loss for each inch of thickness of slate in the parting. This estimate is based on the driving of a 10-ft. entry in a 5-ft. seam, for each inch of thickness of refuse in the seam, the price of mining being 90c. per ton of coal loaded.

It appears to me that this would be a fair compensation to be paid the miner for his deadwork in handling the refuse in such a seam. If the width of the entry is increased to 12 ft., the payment for deadwork would be increased in the ratio 12: 10, or 1.2 times. The payment for yardage in such an entry would then be 1.2 × 9 = 10.8c. per in. of thickness of refuse parting. On the other hand, if the width of the entry is but 8 ft., the payment would be 0.8 × 9 = 7.2c. per in. of refuse, for each yard of entry driven.

In coal mining, as in other industries, there are always some honest fellows who plug along when working under difficulties such as these. They make no claim for extra pay, until the work becomes really burdensome. However, when you analyze the situation and consider the conditions that exist in the seam, nothing can be fairer than to establish a price based on such conditions. Then, as the deadwork increases, and the thickness of the refuse parting grows greater, inch by inch, the price paid compensates fairly for the extra labor performed by the miner. Where such an agreement is made with a man working such a place, little trouble is experienced as he is generally satisfied.

Edwardsville, Penn. LEWIS R. THOMAS.

Firebosses as State Officials

Letter No. 2—Referring to the statement made by Fred Turner, *Coal Age*, Jan. 30, p. 245, regarding the attitude of some firebosses toward the state mining law, and their responsibilities for the safety of the men employed in the mine, it appears to me that any fireboss who fails to comply with the state law, or is willing to do things that he knows are unsafe should have his papers taken from him.

Mr. Turner states that he knows of firebosses who would do anything they are told, without regard to whether the acts are lawful or dangerous to the men working in the mine. Speaking of the fireboss, he says, "His refusal to obey the orders of his foreman would result sooner or later in his discharge." While that may be true, it is no excuse for a fireboss doing anything contrary to the state law, or permitting practices that he knows are dangerous.

A fireboss that has the ambition to do his work well and conscientiously will act the same whether he is employed by his company or the state. Safety is his first consideration, and he will let nothing else control his actions. Suppose, for a moment, there is an entry where firedamp has collected. If the mine foreman told a fireboss to go and touch a match to the gas, do you suppose he would obey such an order? Then, why assume that firebosses are afraid to refuse to comply with any order that they know is unsafe or contrary to the requirements of the mining law. What firebosses need is a little backbone, which will give them all that is coming to them.

Having worked for a great many mine foremen, as fireboss and assistant foreman, I can say with truth that I have never yet seen the foreman who has asked me to do anything that would endanger the lives of those at work in the mine. The advice of these foremen has always been to "go safe." It is my belief that few operators, if any, would stand for a foreman in their employ, ordering or asking a fireboss to do anything that would be unsafe or contrary to law. A fireboss receiving an order of that kind from his foreman should appeal at once to the superintendent or manager. By so doing, he would prove his efficiency and value.

Speaking of efficiency in a fireboss, let me say that it is not alone his compliance with the law and keeping the mine safe; but his efficiency will depend also on his ability to handle successfully the men in his charge, and look after other matters in his section. By observing where timber, ties and rails need to be removed from places that are abandoned, and taking note of other things, in his efforts to coöperate with the foreman, a fireboss will prove his value in the daily operation of the mine. Firebosses would derive much benefit from meeting together and talking over matters pertaining to their work in the mine. By so doing, they would get better results and be more efficient.

Chambersville, Penn. JOHN BUGGY.

Belting for Anthracite Breakers

Letter No. 1—A short time ago, I remember there appeared in *Coal Age* (Feb. 27, p. 419), an inquiry by a mechanical engineer who asks for an estimate on the quantity of belting required in the operation of an up-to-date anthracite breaker, on the basis of tonnage of coal handled in the breaker.

Having recently designed such a breaker located in this city and which is 80 per cent. complete, it gives me pleasure to offer the following, in respect to the quantity of belting and rope drives employed:

Two rope drives, requiring 160 ft. of rope;
Eight rubber-belt drives, requiring 415 ft. belting;
Three jig drives, requiring 75 ft. belting.

This plant is designed to prepare and ship to market about 500 tons of coal per day.

FRANK B. DAVENPORT,
Mining and Mechanical Engineer.
Wilkes-Barre, Penn.

Living Conditions at Mines

Letter No. 2—One who has spent all his life, as I have, in and around coal-mining towns, cannot fail to read with deep interest the excellent letter, regarding the effect of living conditions on the successful operation of coal mines, by A. A. Allen, *Coal Age*, Feb. 13, p. 331. The reading of that letter inclines me to add a word or two from my own experience that may he helpful, and I hope to see the subject discussed thoroughly, as it is an interesting one to all who have the welfare of miners at heart.

Being a miner myself, there are two things that I have always noted are a characteristic of this class of workers; and I believe other mining men will bear me out in what I am going to say. When the average miner *works* he works hard, under almost any kind of conditions. When he *plays* he plays hard, which is proved by the fact that our best baseball, football and basketball teams come from mining towns. Now, one can readily judge that men having these characteristics must be provided with surroundings that will appeal to their tastes and assist their development.

My observation and experience compels me to conclude that, in the large majority of our mining towns, coal miners are required to live under the most meager conditions, their lot being worse in this respect than that of any other class of industrial workers. My belief is that it causes the present unsettled condition of miners. They move from one place to another, looking for better conditions in which to live and rear their families, but too often their search is vain.

Conditions Underground Good, But No Living Accommodations in the Place

Only recently, I was called to look over a proposition where a foreman was wanted. I found conditions in the mine the very best, but the living conditions in the town were unbelievable, in one or two respects. In reply to my inquiry as to where I could find a temporary boarding place, the superintendent loked half ashamed and said, "I don't think there is a place in town where an English-speaking man would care to stay."

The roads in the town were poor, there were no churches, no places for amusement or recreation, and one can judge of the sort of schools that would be found there. To move to such a place, a good miner would have no desire. The class of men employed there were largely given to drink and carousing Sundays and other days when they were not working.

Contrast these conditions with those existing in a mining town where the roads are good, and where there are good schools and churches and comfortable houses are provided for the men. The town is kept in a sanitary condition. The miners are not unsettled and restless, but are a satisfied lot, as one observes them. While there may be one or more saloons in the place, there is not the hard drinking and carousing that characterizes the towns to which I have just referred. A miner may go to a saloon, get a drink and stroll out to see the boys play ball or some other game but after that, he returns home none the worse for his manner of spending the few hours he has above ground.

Labor, Booze and Living Conditions

The statement has been made that to abolish booze would solve the labor troubles. In a sense this may be true, as too many men drink hard and forget to report for duty if, indeed, they are in fit condition to work. Now, I am not speaking a word in favor of booze, as I am a strict temperance man, myself. Let me say, however, that I am convinced that the only way to better labor conditions in coal-mining is to improve the living conditions at the mines. Provide good schools and churches, good roads and comfortable houses with yards and gardens, and see to it that there are places of amusement and recreation. Last but not least, make the town sanitary and a fit living place where a man can safely bring up his family.

At the mine, a good warm wash house should be provided where the tired miner can wash himself and change his clothes before going home. If these conditions prevail at a mine, there need be little fear that miners will become restless. Under proper management, the conditions I have just cited can be made self-supporting, and it goes without saying that they would secure and hold a better class of miners, which would mean an increased production of coal because of fewer idle days when men fail to report for work.

Johnstown, Penn. Optimist.

Efficiency in Firebossing

Letter No. 11.—Having been a fireboss myself for a considerable time, I always try to sympathize with the fellow who is unfortunate enough to hold that position. I regard it as the most responsible position in a coal mine, and one that should only be given to men whose ability and courage cannot be questioned, inasmuch as the safety of all the men working in the mine is dependent on the fireboss.

The fireboss' task begins when he leaves his bed in the early morning and prepares to enter the mine. On reaching the head of the shaft or slope, he must assemble all his thinking powers for action. In the performance of his work, his ear must ever be alert to catch the sound of a crack or break in the roof or the timbers supporting it. His watchful eye must be able to detect the presence of even a small percentage of gas, by observing its first appearance on the flame of his safety lamp, which is the only light he is permitted to carry when making his examination of the mine.

What the Mine Foreman Expects of the Fireboss Beside His Regular Duties

In addition to the duties that pertain particularly to his office as fireboss, he is expected, by the mine foreman, to make mental note of the number of loaded and empty cars standing in the working places and to be able to describe the condition of each place in his section, in respect to its condition and need of timber or tracking, and report these and other things that may require immediate attention.

On his return to the shaft or slope bottom, his report having been entered in the fireboss book, he must next attend to the miners who are now entering the mine, and notify any who are working in places that he has found to be unsafe, not to go into their places. A little later, he must return to the working face and see that miner 289, or miner 683, has taken down that loose piece of bad top, before proceeding to load any coal, after which he must assist the bratticeman in removing gas from a pitch heading. The fireboss, in answer to the inquiries of the foreman, is supposed to know why John Popolaski, or Salvatore Angelo, are not at work in their places.

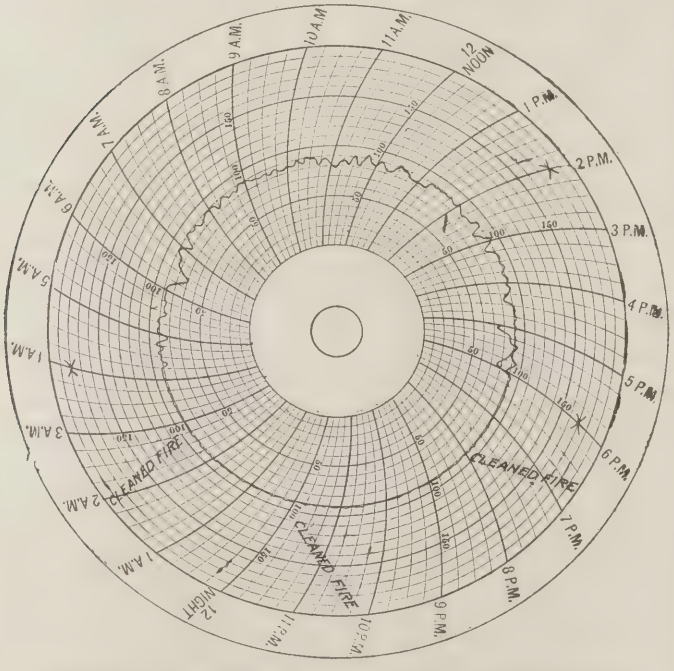
These and many other numerous tasks fall to the lot of the busy and efficient fireboss. When he at last starts back to the foot of the shaft, ready to return home, it is only to meet the foreman, who wants to know "Why in h—, is there no more coal coming out?" Yes, the fireboss, if he is a good conscientous fellow, has a happy life of it whenever the foreman so determines.

West Pittston, Penn. Richard Bowen.

[The discussion of "Efficiency in Firebossing" will close with Letter 15, now on hand.—Editor.]

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD



A Remarkable Pressure Chart

I am sending the inclosed Bristol's recording-pressure chart, which represents a 24-hour run at the power plant of the Miami Valley Hospital of this place, and wish to ask for the opinion of *Coal Age* and its readers regarding the chart. It will be observed that the first dayman is in charge doing a 10-hour shift extending from 4 a.m. to 2 p.m.; the second dayman works a 4-hour shift from 2 p.m. to 6 p.m. and is followed by the nightman who works another 10-hour shift, from 6 p.m. to 4 a.m.

The point to which I wish to draw particular attention is the fact that the nightman saved 30 per cent. of coal on his run and, as indicated on the chart, cleaned the fire three times, in his 10-hour shift. He states that the boiler popped off three times in the same shift. The furnaces are fired by hand and equipped with shaker grates. The chart shows the pressures recorded during each shift and speaks for itself, no further comments being needed. I shall be glad to learn the opinions of experienced engineers and firemen who have used this form of pressure chart.

W. F. HARRY, Chief Engineer,
Dayton, Ohio. Miami Valley Hospital.

The remarkable feature of this chart, which is accurately shown in the accompanying figure, is the uniform pressure line recorded during the nightman's shift. Taken in connection with his statement that the boiler popped off three times during that shift, and the further fact indicated on the chart that the fires were cleaned three times in the same period, one feels justified in assuming that the showing on the chart is not a correct representation of the pressure in the boiler, during the night shift.

BRISTOL PRESSURE CHART OF A POWER PLANT

If the boiler popped at all at this pressure, it would have kept on popping if the chart is a correct showing. The only conclusion is that the gage was spiked by the nightman, with the probable intention of producing such a uniform chart, believing that this would reflect credit on him as showing constant attendance on his duties as fireman. In the absence of exact information, it may be assumed that the plant was carrying a fairly uniform load during the day shifts, and the slight irregularity of the pressure line during those shifts is no more than what might be expected especially in a hand-fired plant. Referring to the statement that the nightman saved 30 per cent. of coal on his run, the meaning is somewhat obscure. It is only natural to suppose that there would be a considerable less coal used to run the plant during the night than during the day, and the 30 per cent. saving claimed for the night shift has no particular significance.

From the appearance of the chart, it can be said with some degree of certainty that the dayman who came on at 4 a.m., cleaned fires two hours later, at 6 o'clock, causing a well-defined drop in pressure for a half-hour period. From that time, the chart does not show, by any undue pressure drop, that the fires were cleaned again during the day.

We feel safe in assuming that the night man coming on at 6 p.m. probably did clean fires two hours later, as marked on the chart. We can see no reason, however, why it would be necessary to clean the same fire four hours later, midnight, and again at 3 p.m. The three cleanings marked on the night run would seem to refer to three separate fires. We shall be glad to receive the opinions of our practical readers.

Three Common Safety Lamps

Please explain in *Coal Age* the important differences between the Davy, Clanny and Wolf safety lamps.

Johnstown, Penn. ASST. FOREMAN.

The chimney of the common Davy lamp consists entirely of wire gauze, while in the Clanny and Wolf lamps the flame is surrounded by a glass cylinder surmounted by a wire gauze. The Davy lamp is often provided with a metal shield, which partially encircles the gauze chimney and protects the flame from strong drafts. The Clanny and Wolf lamps may or may not be provided with a steel bonnet. The bonnet of a Wolf lamp is corrugated and has tangential openings that afford a less resistance to the burnt air and gas issuing from the top of the lamp. While the Davy and Clanny lamps burn lard, cottonseed or sperm oil, the Wolf lamp is designed to burn a volatile oil, as naphtha or naphtha benzine. The oil vessel is filled with absorbent cotton, in order to lessen the danger arising from the use of the volatile oil. The Wolf lamp is also provided with an igniter to relight the flame when extinguished.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Alabama Firebosses' Examination Birmingham, Jan. 20-23, 1919

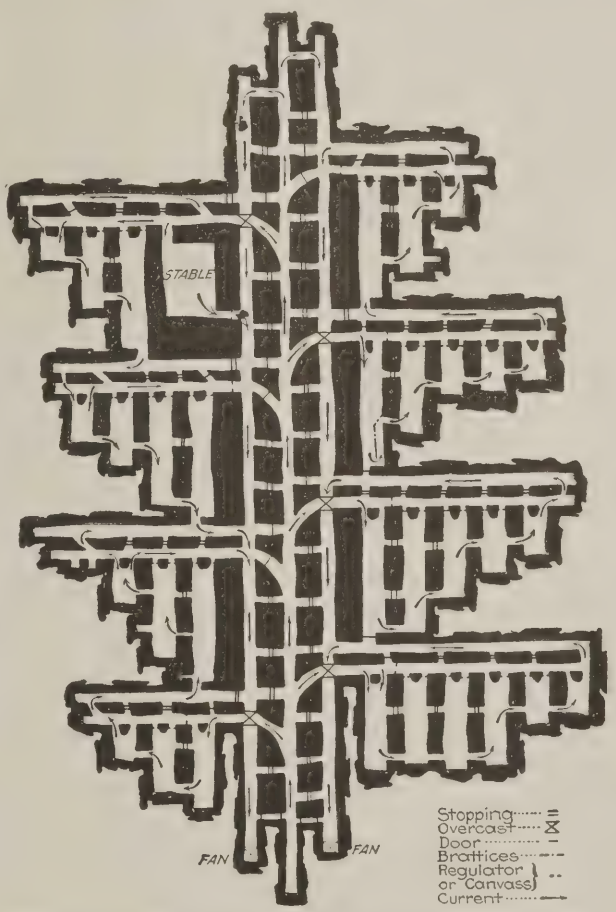
(Selected Questions)

Ques.—Give the names, chemical symbols and composition of the different gases met with in coal mines.

Ans.—The common mine gases are the following: Methane or marsh gas (CH_4), consisting of one atom of carbon combined with four atoms of hydrogen; carbon dioxide (CO_2), consisting of one atom of carbon combined with two atoms of oxygen; carbon monoxide (CO), consisting of one atom of carbon combined with one atom of oxygen; hydrogen sulphide or sulphureted hydrogen (H_2S), consisting of two atoms of hydrogen combined with one atom of sulphur. In addition to these common mine gases may be mentioned the heavy hydrocarbon gases, olefiant gas (C_2H_4), consisting of two atoms of carbon combined with four atoms of hydrogen, and ethane (C_2H_6), consisting of two atoms of carbon combined with six atoms of hydrogen. Methane or marsh gas is a light hydrocarbon and is sometimes called "light carbureted hydrogen." Though not mine gases, properly speaking, there may be mentioned in this connection the oxygen (O_2) and the nitrogen (N_2) of the atmosphere. Under certain conditions, there may also be present in the mine small quantities of hydrogen (H_2).

Ques.—Are there any conditions under which the flame will pass through the gauze of a safety lamp? Explain fully.

Ans.—If the gauze of the lamp becomes heated to low redness in the dark, it is extremely unsafe and flame is liable to pass through the mesh. Also, if the



FLAME PASSES TROUGH WIRE GAUGE WHEN HEATED

gauze is dirty, or the lamp is exposed to a strong air current or blast of air, or the lamp falls, or if the gauze is defective or has been injured in any way the lamp is unsafe and liable to pass flame through its gauze, especially if handled by an incompetent person.

As shown in the accompanying figure, when the gauze has become sufficiently heated, its cooling effect is destroyed and the flame passes through the mesh, because the wires no longer absorb the heat from the tiny streams of gas and air passing through the gauze and the flame continues to burn instead of being extinguished, as is the case when the wires are cool and able to absorb the heat from the burning gas.

Ques.—How many cubic feet of air must be mixed with 1 cu.ft. of firedamp to render it harmless?

Ans.—Assuming the firedamp is a mixture of pure methane and air, in the most explosive proportions, or contains 9.46 per cent. of gas, 1 cu.ft. of the firedamp will contain 0.0946 cu.ft. of gas. But, taking the lower inflammable limit of the mixture as reached when it

SHOWING PROPER VENTILATION OF MINE PLAN

contains 2.5 per cent. of gas, the volume of air and gas will then be $0.0946 \div 0.025 = 3.784$ cu.ft. Now, subtracting the original cubic foot of firedamp from this volume gives 2.784 cu.ft. of air to be added to bring the mixture to the lower inflammable limit. For safety, it would be well to add 3 cu.ft. of air to provide a good margin.

NOTE—Candidates in the firebosses' examination, as well as in the first- and second-class examinations, were required to ventilate the map shown in the accompanying figure. The circulation shown in the figure, of course, did not appear in the original map given to the candidates, but has been carefully indicated here in order to show the proper manner of ventilating the mine.—EDITOR.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Canary Islands Lost Bunker Coal Trade During 1917

The inhabited islands of the Canary Archipelago (Teneriffe, Grand Canary, Palma, Lanzarote, Fuerteventura and Hierro) have experienced great economic and financial depression during 1917 as a result of the war. The withdrawal of all but Spanish vessels from Canary Island ports closed down the bunker-coal trade abruptly. This trade, which in 1914 was valued at $10,000,000, ceased in January, 1917. No collier entered these ports during the year except small coastwise steamers carrying 300 to 400 tons of low-grade Spanish dust coal. In 1917 there were no imports of American coal, which in 1916 showed a landed value of $167,840. The total imports of bunker coal in the Canary Islands in 1916 amounted to 110,270 metric tons, valued at $573,102. In 1917 the tonnage dropped off to 42,000 metric tons, valued at $281,450.

Germany to Retain Saar Valley

According to recent reports from Paris, the Saar Valley problem has been solved by an economic agreement that will give France certain concessions in the coal supply of that region but which will not militate against German sovereignty. It will be recalled that the French Government has been insisting for some time that the Saar Valley, with its rich coal deposits, be given over to her, basing her contention on the fact that the Germans destroyed the coal mines in the Lens region of France.

All French plans to dominate the Saar Valley and to obtain the entire coal output of the region until the Lens mines were again in operation met with stubborn resistance. The disposition of this question has possibly been the most bitterly fought of all the issues before the peace conference.

Foreign Trade Opportunity

An American consular officer reports that a man in Sweden wishes to secure an agency for the sale of the best quality steam coal. Those who are interested may obtain the name and address by addressing the Bureau of Foreign and Domestic Commerce, or any of its branches, and referring to Opportunity Number 29009. Correspondence with the Swedish agent may be in English.

Foreign Freight Rates

W. W. Battle & Co.'s coal trade freight report under date of Apr. 17:

During the past week we chartered a number of sailing vessels to carry coals to South American ports, and have a few additional sailing vessels open for this business; but steamers for these destinations are difficult to obtain. We also chartered a number of steamers to carry coals to West Indian ports, and have additional tonnage offered at the Chartering Committee's rates.

We would quote the Chartering Committee's rates as follows:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge. Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis., or $21 net, 600 tons dis.; Buenos Aires, $18.50 net, 600 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.50 net, 500 tons dis. To Nitrate Range, $16.50 gross prepaid.

Sail (maximum)—Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Rio Grande do Sul, $21.50 net, 400 tons dis.; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. To Nitrate Range, $16.50 gross prepaid.

American Ambassador Edwin V. Morgan reports from Rio de Janeiro, Brazil, under date of March 27, that an executive decree has been signed withdrawing from foreign vessels the privilege granted by decree 12734, of Dec. 5, 1917, to engage in Brazilian intercoastwise trade.

Coal and Coke Exported from New York in February

Only in the quantity of coke exported from the Port of New York during February of 1919 is there shown an increase as compared with the same month in the two previous years. As compared with February in 1917 and 1918, the tonnage of anthracite and bituminous exported from this port shows a decrease, which may be due in most part to the mild winter and the consequent small consumption. The tabulation below gives tonnage and value:

	Anthracite						Bituminous						Coke					
	1917		1918		1919		1917		1918		1919		1917		1918		1919

COAL AND COKE NEWS

EDITED BY ..... MOSS

Harrisburg, Penn.

Considerable interest has been aroused by the offer of the Susquehanna Collieries Co., owner of two collieries at Lykens and Williamstown, Dauphin County, to sell its holdings to any responsible purchaser. It has advertised to this effect in the Dauphin County papers, but no buyer has appeared to date.

The offer was prompted by the fact that advisers engaged by the Dauphin County commissioners as coal-land experts have appraised the value of the Susquehanna's Dauphin County holdings at $87,000,000. The company is willing to dispose of the whole tract, with improvements, for $1,400,000, of which $400,000 represents the improvements. This is considerably less than 2 per cent. of the appraised value, yet nobody has so far appeared anxious to take a profit of about $85,000,000 by putting up $1,400,000. It would seem to be the impression of possible investors that the property is not worth what the county's advisers say it is.

According to mining men, the problems presented in this particular property make it the hardest mining job in the anthracite region. One of the mines hoisted 13¾ tons of water for every ton of coal hoisted in 1918, while at the other mine the ratio was 22¾ tons of water for every ton of coal. One mine used 22 per cent. of its output for boiler fuel, while the other used 40 per cent. A hearing on the appeal from the new valuation will be held by the Dauphin County commissioners Apr. 17.

With the basic purpose in mind of allowing anthracite coal to be taxed without having it declared unconstitutional by the courts, Senator A. L. Davis, of Lackawanna, in the Senate on Apr. 9 introduced a joint resolution proposing an amendment to article nine of the constitution. The amendment follows:

"Section 16—For the purpose of taxation, subjects of the same nature may be classified according to their physical character or their general use and all subjects of taxation may be classified for the purpose of laying graded or progressive taxes."

This amendment will have to be passed by this legislature and the one two years hence, and then submitted to the people, before it becomes a law.

Senator Davis states that the real purpose in introducing the amendment was so that anthracite coal could be taxed without the courts declaring this method of taxation unconstitutional. There are on the statute books of the state two measures, the Roney bill and the Dawson bill, calling for a tax on anthracite. These measures were passed and signed at the 1915 and 1917 sessions for the purpose of assisting in remedying the mine-cave situation in the anthracite region.

Uniontown, Penn.

Not since 1907 have conditions in the Connellsville bituminous region been at such low ebb as at present. The entire region is now operating upon a basis of 44 per cent., with 50 coke plants and three times as many coal plants entirely out of operation and all others operating upon a greatly restricted basis.

The action of Director General Hines in refusing to accept the Peek-Gary steel price schedule has served to cloud the immediate future of the coke industry with more uncertainty than existed before the conferences were started. The first effect of the present controversy has been to cause a drop of from $4.50 to $4.25 in the average price of coke, which was quickly followed by another retrenchment period on the part of the operators. A week ago there was a consensus of opinion that rock bottom in curtailment had been reached. Now nobody will venture a prediction on how much lower it will go.

Four dollars seems to be the lowest figure at which operators can sell any considerable tonnage of coke. Demands of buyers for a lower price has resulted in suspension of operations at a number of plants. For odd lots of coke, however, the price has gone as low as $3.75, ovens, and in one instance an operator accepted that price on a contract for a limited period because mining conditions forced him to continue operations, even at a loss. Prompt furnace coke is selling from $4 to $4.50, but the range for contracts runs the line from $4.50 to $6 with most of the tonnage delivered around $5.

Output of the Alicia plants recently sold by W. Harry Brown is now being delivered to the Monessen plant of the Pittsburgh Steel Co. The Rostraver dock has been put back into commission after having been rebuilt following its destruction by fire last summer.

Charleston, W. Va.

Coal production in West Virginia during the first few days of April had not regained its stride, even though statistics covering March shipments showed that there had been an increase in the output during that month as compared with February production. In other words, insofar as it was possible to tell, the output was just about at the point it had reached during the early part of March. In certain districts the idle mines were more numerous than they had been in the previous fortnight, and in no district was there any increase insofar as it was possible to estimate.

Taking the state as a whole, the output was not much over 40 per cent. of the total full-time capacity of the mines. Even such business as there was came from consumers who were simply keeping their stocks from running too low and could not be attributed to any additional consumption of coal. On a rough estimate, shipments from West Virginia fields in March exceeded those in February by from 5 to 10 per cent. During the week ending Apr. 5 railroad fuel shipments were somewhat curtailed. Tidewater shipments to all points except Hampton roads were fairly large. On Apr. 1, when the coal year opened, much coal tonnage was not yet under contract, that being especially true as to lake shipments and as to coal for shipment to the West in general.

Improvement marked the course of events in the Fairmont region during the first five days of April. Despite such improvement, however, there was no decrease in the number of idle mines. The improvement was applicable to western as well as to eastern consignments. Production in the Fairmont field was less than half of normal.

At the outset of April New River operators were still being somewhat hampered in their attempt to make eastern shipments by the existence of several embargoes on coal, although the Navy continues to use a large quantity of fuel from New River mines. Much of the tonnage usually going to tidewater is already under contract for the coming year. It will require an increase in western business to simulate production to any appreciable extent in the New River field. Pocahontas production was diminished somewhat through market conditions.

The condition of the western market was reflected to some extent in the Logan Mining District, where there was a slight decline in production during the week.

Insofar as it was possible to tell production hardly held its own in the Kanawha region during the first five days of April. Further gains will not be made until the opening of the lake trade season, and until that time most of the miners will not average over two days a week. There was some encouragement in the fact that March shipments exceeded February shipments by about 10 per cent. Much coal from the district is still not under contract.

Victoria, B. C.

When the British Columbia Legislature prorogued a few days ago the Lieutenant Governor withheld his assent to the Settlers' Rights Act of 1919, which would have given the old settlers, or their dependents, with homes in the Esquimalt & Nanaimo Railway Belt on Vancouver Island a further opportunity to make application for the coal rights in connection with their property. The issue now is straight cut between the jurisdiction of the Dominion and the Province, and the stake to those directly interested in title to a large section of coal-bearing lands of the Island.

On the question of jurisdiction the Province maintains that it has absolute power with respect to the administration of matters pertaining to civil and property rights, within which classification comes the proprietorship of the coal referred to. Just what position the Dominion government takes it is not so easy to define, but that it is responsible for the Lieutenant Governor's action in refusing to give his assent to the enactment of the Legislature there is no doubt. It may be that its argument is that title to surface and under-surface rights in these Island lands passed from the Province to the Dominion, and from the latter to the Esquimalt & Nanaimo Railway Co., in 1884; that the Esquimalt & Nanaimo Railway Co. since has sold the under-surface rights to the Canadian Collieries (D), Ltd., and that the latter, having raised a considerable sum on this security, should be protected, if only in justice to the bondholders.

It is to be noted that, because of the action taken by the Dominion Government, the Province finds itself in the position of being forced to defend its right to the sole administration of "property and civil rights" within its domain. These rights are part and parcel of the "Terms of Union" and it is considered most serious, apart altogether from the rights of the Canadian Collieries or of the settlers affected, that the Federal Government should so interfere with Provincial legislation of this character. It is very probable, therefore, that both because it believes the settlers have a good case and have been unjustly treated and because the powers granted the Provinces under Confederation must be upheld that British Columbia will not allow the matter to drop where it now stands.

PENNSYLVANIA

Anthracite

Hazleton—The sixteen collieries of the Lehigh Valley Coal Co. in this district have resumed full-time operation. A number of independent operations that had been working only three days a week will also go to a full-time schedule. The resumption of activity is attributed to the action of Governor Sproul sustaining the prospective increase in the price of anthracite.

Freeland — Indications that the Sandy Run mine of the Kemmerer Coal Co. is to be idle for some time have been given by the action of the officials in ordering the men to remove the mules from the mines. The animals are being sent to pasture on ground owned by the company in Carbon County.

Pottsville—Members of the City Council have gone after the Pennsylvania Railroad Co. for persisting to burn soft coal in its engines in that town. An ordinance has been passed providing a fine from $10 to $100 for every day's continuance of the smoke nuisance. Pottsville officials argue that the railroad company should not attempt to burn bituminous coal in an anthracite mining center.

Hazleton—Though miners of the Lehigh coal field are working on reduced time because there is no market for coal, a famine exists in Hazleton and people can not get enough fuel. They let their stocks dwindle, thinking the mild winter weather indicated an early spring. As a result they were caught unawares when the temperature dropped during the week. The mines are operated only two and three days a week, and coal dealers find they can not catch up with orders.

Bituminous

Greensburg—Fire recently destroyed one of the buildings at the No. 2 plant of the Alexandria Coal & Coke Co., located near New Alexandria, with loss estimated at about $10,000.

Charleroi—The Union Coal & Coke company, which operates all of the mines in the Pigeon Creek valley with but one exception, has moved its general offices from Monongahela to Farmers and Miners Bank Building of Bentleyville. The company purchased the Kuhn interests in several thousand acres of coal lands in Scenery Hill and it is reported will develop that tract in the near future.

WEST VIRGINIA

Monon—An improvement in market conditions has enabled the Monongahela Coal Co. operating at this place to start its mines going once again. More than 100 miners are employed at the plant.

Switchback—The Pocahontas Fuel Co. is considering plans for the construction of a large new coal tipple at its local properties, to provide for increased capacity.

Affinity—The Pemberton Coal Co. has recently commenced the construction of a new power plant and machine shop at its local plant, to be used to facilitate operations. It is understood that a new recreation hall and the construction of a number of miners' residences are also contemplated.

Fairmont—The purchase price paid for a one-half interest in the North Fairmont Coal Co. by Robert Talbott, who acquired such an interest in the concern from Seymour McIntire, W. D. Reed and M. A. Joliff, is said to be $150,000. The company has its operation in the Fairmont field, its property being between Fairmont and Morgantown.

Bluefield—M. H. Pedigo, Bluefield, and William H. Leckie, Welch, have recently completed negotiations for the purchase of extensive coal properties located on Pigeon Creek, in McDowell County, comprising a total of 1500 acres, and are understood to be arranging plans for the installation of the necessary mining machinery for extensive development.

Nitro—Plans are under consideration by the Fryland Coal Co. for the installation of new equipment and mining machinery, etc., for the development of two new coal mines located in the vicinity of Nitro. It is understood that in connection with this work the company is planning for the construction of a number of miners' residences for its employees. C. G. Howland is president. The entire work is estimated to cost approximately $50,000.

Fairmont—Another phase in the development of the plans of the Domestic Coke Corporation, of this city, engaged is completing a $3,000,000 byproduct plant, is the awarding of a contract for the construction of two miles of railroad from the site of the plant to the Baltimore & Ohio R. R., such work together with the rights of way necessary to cost about $125,000. This is one of the companies in which capitalists identified with the Monongahela Valley Traction Co. are also interested. At the present rate of progress executives of the company are confident that the new plant will be completed early next spring.

Omar—The tonnage of the Main Island Creek Coal Co. will be appreciably increased upon the completion within the next 30 days of the Logan Southern R. R. from Omar to Sterrett, a distance of ten miles, the Main Island company having changed the name of Crane to Sterrett when many improvements were started there with a view to making it one of the large plants of the company. The holdings include a large acreage of coal of excellent quality which it is proposed to mine on an extensive scale. There has been a large influx of miners since improvements were initiated, and when the new road permits the shipment of even more coal Sterrett will become one of the most important shipping points in the Logan field.

INDIANA

Jasonville—The supply house and blacksmith shop at the Green Valley mine has been burned with loss of $2000, covered by insurance.

ILLINOIS

Nilwood—The Union Fuel Co. has purchased the mine of the Nilwood Mining Co. for $350,000.

Marion—The Peabody Coal Co. is installing at its No. 3 mine at Marion a large crusher which was made by the Link-Belt Co., of Chicago. The crusher has a capacity of 2500 tons per day and will produce a product of 1½-in. cubes of coal.

Du Quoin—Drilling has been started on the Wabash, Chester & Western R. R., ten miles west of here, on 7000 acres of land which have been leased by Crawford & Hagler. It is reported that results of the drilling indicate that a large mine will be sunk near the location soon.

Du Quoin—At a recent election among the miners of the Ninth Subdistrict, which embraces all of Franklin County, the proposition to continue the payment of $750 death fund was defeated. The per capita assessment on the miners was unusually heavy during the recent influenza epidemic, and in addition to this a number of deaths resulted from the Royalton mine explosion last year. The treasurer of this subdistrict, which is the largest subdistrict in the State of Illinois, during the epidemic period paid out $22,500 in claims, with additional claims for $68,000 pending adjustment.

KENTUCKY

Whitesburg—The Wells Coal Co. has recently completed negotiations for the acquirement of the plants of the Salt Lick Coal Co. and the Black Diamond-Elkhorn Coal Co., located in the vicinity of Right Ford of Beaver Creek. It is understood that plans are now being arranged for extensive development operations. The company has also leased additional coal properties in this section, which will also be developed.

ARKANSAS

Clarksville—The King & Johnson Mining Co., of Montana, is understood to have completed arrangements for extensive improvements and extensions in its local coal-mining properties. The plans include the erection of a new coal tipple, electrically operated, with the installation of electric motors and auxiliary apparatus, and the construction of a five-mile railroad branch. The work will involve an expenditure of approximately $150,000.

OKLAHOMA

Tulsa—The B. B. Coal Co. has opened a mine on its holdings just east of Tulsa. This company owns 125 acres underlaid with a vein of coal several feet in thickness and at such shallow depth to permit of profitable working.

Tulsa—Charles Page, oil magnate of this place, has purchased 1000 acres of proven coal lands southwest of here which he will soon begin developing. Mr. Page will build a line of railroad into the heart of this tract to handle the coal mined.

Dawson—Cosden & Co., oil producers, have purchased extensive coal lands at Dawson, four miles east of Tulsa, and will begin taking coal from new mines that will be opened there during the summer. Cosden & Co. own and operate at Tulsa an oil refinery said to be the largest in the world. Since the supply of natural gas in the Oklahoma fields is proving inadequate and is insufficient to operate the refinery, Cosden & Co. are looking elsewhere for fuel. It is the plan to take coal from the recently acquired coal lands for operating the Tulsa refinery.

KANSAS

Pittsburg—Daylight saving to economize on the use of fuel has worked the other way in the Kansas coal fields, so far. Twenty-six coal mines in this district were idle last week because the men would not go to work earlier, and the companies persisted in following the Government time change. An agreement has been reached, however, whereby the men will resume their work on the new time schedule pending a rearrangment of car schedules by the railroads.

NEW MEXICO

Oscura—The Consumers Coal Co. is being organized at El Paso, Tex., by M. D. Gaylord, an experienced coal operator, for the purpose of developing four sections of coal lands in the vicinity of Oscura. The company plans to bring the daily output of the property to 500 tons. The El Paso & Southwestern Ry. runs through the property, which is 128 miles from El Paso.

Foreign News

Victoria, B. C.—Consumers of coal here have now to pay $10.25 a ton and, if they buy it in half-ton lots, at the rate of $10.50 a ton. Shortly before the war the price in this and neighboring cities was $6.50 a ton, which furnishes a good illustration of the remarkable advance which has taken place within a comparatively brief period. The dealers' only explanation is that, as domestic coal has been selling at a lower figure than bunker coal, and as for some reason the sale of bunker coal has fallen off, the mine operators have been obliged to bring the price of domestic coal near the mark of that being sold at the bunkers in order to pay the miners the present high wage scale. They could not explain how it happens that bunker sales have declined, although venturing the suggestion that fuel oil now is being used by many more vessels than in the past.

Toronto, Ont.—The annual meeting of the Canadian Associated Coal Dealers was held here on Apr. 3. The situation was fully discussed, the general consensus of opinion being that there was still a possible danger of temporary shortage in case of a sudden rush of orders, but that this would be averted if consumers would order supplies early. Some advance in prices was regarded as certain. The following officers were elected: T. A .Harrison, Toronto, president; J. M. Daly, London, vice president; B. A. Caspell, Toronto, secretary-treasurer; M. F. Craig, Gueiph; J. A. Maclean, Wingham; J. F. Foulds, Campbellford; G. M. Baker, Lindsay; Edward Browne, Port Hope; G. A. Stanley, Lucan, and G. F. Rogers, St. Catharines, directors. Resolutions were adopted that the Railway Commissioners be requested to give consideration to the inconveniences suffered by coal dealers and attempt to adjust their grievances in a definite period; that the government be urged to continue the office of Fuel Controller in the interests of the public, and that the dealers watch carefully for impurities in coal and demand compensation from shippers, and that the government fix the amount of impurities possible.

Nanaimo, B. C.—There has been litigation during the past few weeks over title to the coal fields of Vancouver Island controlled by the Nanoose Collieries, Ltd., suit being brought against the company by A. F. Eastman, manager of the Marble Bay mines, Texada Island, for an accounting and for an order restraining further work on the property. His claim was that in 1906 he had entered into an agreement with the then owner of a portion of the property now under development to provide money for opening up the coal measures supposed to be there in return for a half interest. Work started on this basis, a small seam was struck not far from the surface, and then a disagreement arose with the result that operations were suspended. Mr. Jack subsequently died. His executors, according to Mr. Eastman, declared that the estate would sell its interest for $60,000, whereupon Mr. Eastman et al arranged to dispose of the entire holdings to Alvo von Alvensleben, the German financier and propagandist, of whom considerable has been heard both in Canada and the United Stated of late years, for $125,000. This, however, was not accepted by the executors, and Alvensleben bought the Jingle Pot mine, near Nanaimo, B. C. Finally the property was sold out to the Nanoose Collieries, Ltd. The reply to Mr. Eastman on behalf of the company was that his arrangement with Mr. Jack was to the effect that he should have one-half of the returns of coal produced during the active operation of the partnership. The court upheld the company and the action was dismissed.

Personals

W. C. Gartley, formerly with the H. C. Frick Coke Co., at Maxwell, Penn., has accepted a position as superintendent with the Maple Glen Coal works at Shoring, Penn.

J. A. Bier has resigned as superintendent of the Williams Run Coal Co. and Anita Coal Mining Co., Punxsutawney, Penn., and is now connected with the Hurlburt Grease and Oil Co.

Joseph Maize, of Wendel, Westmoreland County, Pennsylvania, has resigned his position as superintendent of Edna Nos. 1 and 2 mines of the United Coal Corporation, effective Apr. 16.

B. H. Armstrong recently assumed the duties of superintendent for the Citizens' Coal Mining Co., of Lincoln, Ill., succeeding **William D. Obcamp**, who was formerly superintendent of the Lincoln mine.

Robert Whitehead, well known in southern Illinois coal-trade circles, has joined the sales force of the New Kentucky Coal Co., 1700 Fisher Building, Chicago, of which H. L. Keiflein recently became vice president and manager.

Henry Blackledge, formerly with the Pittsburgh Coal Co., in Washington County, has been appointed superintendent of Mines Nos. 88, 89 and 90 of the Consolidation Coal Co., with headquarters at Wyatt, W. Va. He succeeds **W. E. Lakin**, resigned.

A. T. Pace has been reappointed as traveling auditor for the United Mine Workers of America in the 12th district, by President Frank J. Hayes, of Indianapolis, Ind. His territory is in southern Illinois and includes Williamson, Franklin, Saline, White and Gallatin Counties.

J. D. Mooney, recently discharged from the Army after having served overseas as a captain with the 309th Ammunition Train, 84th Division, is now with the General Motors Corporation, New York. Mr. Mooney was manager of the Hyatt Roller Bearing Co.'s industrial division prior to joining the army in 1917.

R. W. Belcher, who has been identified with civil service work, has been elected secretary of the War Service Executive Committee of the Chamber of Commerce of the United States to take up the work inaugurated by W. H. Manss at the great reconstruction conference of American business, held at Atlantic City last September.

T. L. Cole, formerly assistant in the sales department of the New York Coal Co., Columbus, Ohio, has resigned to take a position with the Kendall Coal Co. **C. C. Everhart,** who was the Detroit representative of the New York Coal Co., has resigned his position, being succeeded by **John F. Nuebacher,** formerly with the Semet Solvay Co. C. C. Everhart has gone into the jobbing business in Detroit.

James D. Monie has resigned as chief clerk of the New York office of the Tidewater Coal Exchange and on Apr. 15 became New York sales manager of the Johnstown Coal and Coke Co. Mr. Monie has been with the Tidewater Coal Exchange since its organization. The office of the Johnstown Coal and Coke Co. will be removed from the Park Row Building to the Maritime Exchange Building, 80 Broad Street.

W. H. Ashlers has been made assistant secretary and treasurer of the Rackett Brook Coal Co., Carbondale, Penn., and **Edward B. Burr** has been appointed general superintendent of operations. The former takes a newly created position and the latter the place of **E. H. Leaning,** who has had charge of operations for the past three years. Mr. Leaning is still identified with the Nay Aug Coal Co. and will probably devote his entire time to the operations of that company.

Obituary

William Clayton, pioneer operator and one of the first to sink a mine in the Standard field of Illinois, died recently at his home in Collinsville. He sank two mines near Collinsville 35 years ago and afterward sold them to the Consolidated Coal Co., of St. Louis.

Harvey Miller, 40 years of age, a prominent coal and lumber man of eastern Kentucky, recently died at his home near Whitesburg, Ky., of influenza. Mr. Miller held title to several fine coal properties and had a number of hardwood tracts, operating several mills.

D. E. Adams, a leading coal merchant of Winnipeg, Man., and a pioneer of the business in Western Canada, died on Apr. 3 at Pasadena, Cal., where he had been spending the winter on account of ill health. He came to Winnipeg from Toronto in 1882 and entered the coal business as representative of the North West Fuel Co., of St. Paul, Minn., which was the only concern engaged in the Winnipeg trade at that time. It afterward sold out to the Dominion Coal Co., of which Mr. Adams was manager from 1885 to 1895. He was also connected with the company that was the first to mine Souris Valley coal. In 1904 he became secretary and selling agent of the Tabor Coal Mining Co., which afterward sold out to St. Paul and Minneapolis capitalists who organized the Canada West Coal and Coke Co. Mr. Adams' business was transferred to a joint stock company under the style of the D. E. Adams Coal Co., Ltd. Mr. Adams took a prominent part in the business and social life of Winnipeg and was a Free Mason. He leaves a widow, one son and two daughters.

Coming Meetings

Illinois Mining Institute will hold its annual meeting May 22, 23 and 24. Secretary, Martin Bolt, Springfield, Ill.

National Coal Association will meet May 21, 22 and 23, at Congress Hotel, Chicago, Ill. Secretary, J. D. A. Morrow, Washington, D. C.

Illinois and Wisconsin Retail Coal Dealers' Association will meet at Hotel Nelson, Rockford, Ill., June 4 and 5. Secretary, I. L. Runyan, Chicago, Ill.

International Railway Fuel Association will hold its annual meeting May 19-22 at the Hotel Sherman, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

Retail Coal Dealers' Association of Texas will hold its annual meeting on May 19 and 20 at Fort Worth, Texas. Secretary, C. R. Goldman, Dallas, Texas.

Indiana Retail Coal Merchants' Association will hold its annual spring meeting Apr. 23 and 24 at Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind., subject to ratification of executive committee. Secretary, J. W. Paul, Pittsburgh, Penn.

American Manufacturers' Export Association will tender a luncheon at 12:30 p.m., to all its members who may be in attendance at the National Foreign Trade Convention in Chicago, Apr. 25 to 26, at the Congress Hotel.

Kentucky Mining Institute after having skipped two years, one on account of the war and the other due to the influenza epidemic, expects to hold its annual meeting this year. While the date and place of meeting have not definitely been set, it will probably be held on May 30 and 31 at Lexington, Ky. Secretary, C. W. Strickland, Huntington, W. Va.

Publications Received

Boiler Water Treatment. Department of the Interior, Bureau of Mines. Technical Paper 218. Unillustrated, 8 pp., 5¾ x 9⅛ inches.

Annual Report on the Mines, 1918. Province of Nova Scotia, Department of Public Works and Mines. Unillustrated, 76 pp., 6⅝ x 9½ inches.

Eighth Biennial Report of the State Engineer to the Governor of North Dakota for the Biennial Period Ending June 30, 1918. Public Document No. 26. Unillustrated. 174 pp., 6 x 9 inches.

Geology of the Lost Creek Coal Field, Morgan County, Utah. By Frank R. Clark. Department of the Interior, United States Geological Survey. Bulletin 691-L. Illustrated, pp. 311-322, 6 x 9 inches.

A Summary of Mining in the State of Washington. By Arthur Homer Fischer. Bulletin No. 4. Engineering Experiment Station, University of Washington. Unillustrated, pp. 124, 6 x 9 inches.

Method of Least Squares Applied to Estimating Errors in Coal Analysis. By J. D. Davis and J. G. Fairchild. Department of the Interior, Bureau of Mines. Technical Paper 171. Illustrated, pp. 36, 6 x 9 inches.

Combustion Experiments with North Dakota Lignite. By Henry Kreisinger, C. E. Augustine and W. C. Harpster. Department of Interior, Bureau of Mines. Technical Paper 207. Illustrated; 41 pp.; 6 x 9 inches.

Notes on the Geology of the Murchison District. By J. Henderson, Mining Geologist, Geological Survey Department. Pp. 108 to 112 inclusive of the New Zealand Journal of Science and Technology, March, 1918. Unillustrated, 6¼ x 9¾ inches.

Notes on the Geology of the Waikato Valley near Maungatautari. By J. Henderson, D. Sc., Mining Geologist, Geological Survey Department. Pp. 56 to 60 inclusive of the New Zealand Journal of Science and Technology, January, 1918. Unillustrated, 6¼ x 9¾ inches.

The Geology of the Te Kuiti District, with Special Reference to Coal Prospects. By J. Henderson, D. Sc., Mining Geologist, Geological Survey Department. Pp. 112 to 115 inclusive of the New Zealand Journal of Science and Technology, March, 1918. Unillustrated, 6¼ x 9¾ inches.

Notes on the Geology and Mineral Occurrences of the Wakamarina Valley. By J. Henderson, D. Sc., Mining Geologist, Geological Survey Department. Pp. 11 to 15 inclusive of the New Zealand Journal of Science and Technology, January, 1918. Unillustrated, 6¼ x 9¾ inches.

A Preliminary Report on the Mining Districts of Idaho. By Thomas Varley, Clarence A. Wright, Edgar K. Soper and Douglas C. Livingston. (In coöperation with the University of Idaho.) Department of the Interior, Bureau of Mines. Bulletin 166. Illustrated, 103 pp., 5¾ x 9⅛ inches.

Trade Catalogs

Locomotive Coaling Plants. Roberts & Schaefer Co., Chicago, Ill. Bulletin No. 34. Pp. 68, 9 x 11½ in., illustrated. Typical coal handling plants designed and built by the company.

Boiler Logic. Heine Safety Boiler Co., St. Louis, Mo. Catalog. Pp. 86, 6 x 9 in., illustrated. A treatise on steam boilers, accompanied by a supplement in color of a Heine boiler set over an underfeed stoker.

Use and Abuse of Electric Headlights on Mining Locomotives. Ohio Brass Co., Mansfield, Ohio. Pp. 15, 8 x 10½ in., illustrated. Reprint of a paper read by K. W. Mackall before the Coal Mining Institute of America.

Modern Types of Flory Mine Hoists. S. Flory Manufacturing Co., Bangor, Penn. Catalog 26. Pp. 6¼ x 9 in., illustrated. Taken bodily from the company's general catalog and covers a general line of mining hoists.

Type "C" Roller Bearings. American Roller Bearing Co., Pittsburgh, Penn. Bulletin No. 1004. Pp. 8, 6¾ x 10 in., illustrated. These roller bearings are recommended for use under conditions of medium loads at medium speeds.

Fairmont Coal Augers. Fairmont Mining Machinery Co., Fairmont, W. Va. Bulletin No. 15. Pp. 4, 6 x 9 in., illustrated. Describes a power auger for use in coal 5 ft. thick and over. Emphasis is placed on flexibility and easy portability.

Sullivan "WB-3" Air Compressors.—Sullivan Machinery Co., Chicago, Ill. Bulletin 75-E. Pp. 12, 6x9 in., illustrated. Compressors for general mining, quarrying or contracting work, and to operate coal machines, drills, pumps and pneumatic tools.

"Sergeant" Ticket Cancelling Box. Ingersoll-Rand Co., New York, N. Y. Form No. 9010. Pp. 4, 6 x 9 in., illustrated. Used at ball grounds, moving picture theaters, etc., where great quantities of tickets must be disposed of without the possibility of their ever being used again.

Process and Apparatus for Reducing Coal. H. Adams, assignor to Adams Mining Machinery Corporation, New London, Conn., 1,293,654. Feb. 11, 1919. Filed Aug. 24, 1915. Serial No. 47,064.

Industrial News

Middletown, Ohio—Papers have been filed increasing the capital of the Solar Coal Co. from $100,000 to $200,000.

Dover, Ohio—The Macksburg Coal Co. has been chartered with a capital of $100,000 by L. R. Page, Joseph Jenkins, W. H. Scheu, John Rees and Charles A. Graber.

Wheeling, W. Va.—The Echo Coal Co. has recently filed notice of an increase in its capital from $50,000 to $150,000, to provide for general business expansion.

Ashland, Ky.—The Lackey Mining Co. has filed notice with the Secretary of State of an increase in its capitalization from $12,000 to $50,000, to provide for expansion.

Moundsville, W. Va.—Plans are under consideration by the Mound City Coal Co. for the immediate rebuilding of its tipple recently destroyed by fire, with loss of about $10,000.

Johnstown, Penn.—The Sheesley Coal Co. has filed articles of incorporation with a capital of $50,000 to operate in the Johnstown section. J. D. Sheesley is the principal incorporator.

El Paso, Tex.—The Hines Lumber and Coal Co. has filed notice with the Secretary of State of an increase in its capitalization from $20,000 to $100,000, to provide for general business expansion.

Whitesburg, Ky.—Fess Whitaker and associates have completed negotiations for the leasing of extensive coal properties in the Whitesburg section, and are arranging plans for early development.

Cleveland, Ohio—The Guernsey Land, Timber and Coal Co. has been chartered with a capital of $100,000 by Mark A. Copeland, F. B. Evarts, James F. Walsh, K. Droege and O. E. Schulte.

Whitwell, Tenn.—The Whitwell Coal Co. has filed notice with the Secretary of State of an increase in its capital stock from $50,000 to $100,000. The increase will be used, it is understood, for general business expansion.

Zanesville, Ohio—Papers have been filed with the secretary of state increasing the capital of the Kehota Coal Co. from $1,000,000 to $2,000,000. The increase will be used in the expansion of the operations in this neighborhood.

Marion, Ky.—The Lagrange Mining Co. has been incorporated with a capital of $30,000 to engage in the development of coal properties in the Marion section. J. L. Lane, A. S. Furtwangler and W. A. Barton are the incorporators.

Charleston, W. Va.—The Nelson Coal and Oil Co. has filed articles of incorporation with a capital of $150,000 to operate in the Charleston district. C. W. Morton, Charles E. Krebs and E. M. Johnson are the principal incorporators.

Whitesburg, Ky.—The Southeast Coal Co., Seco and LeViers, Ky., is understood to be considering plans for the installation of new coal-mining machinery for the development of coal properties in the Thornton Creek section, near Whitesburg.

Harriman, Tenn.—The Harriman Coal & Land Co. has been incorporated with a capital of $40,000 to engage in coal-mining operations in the vicinity of Harriman. Brown Crinkley, L. O. Scott and G. W. Chandler are the principal incorporators.

East Burnstadt, Ky.—The Furnie Coal Co. has been incorporated with a capital of $10,000 to engage in the development of coal properties in the vicinity of East Burnstadt. T. S. Lanier, Sr., Richard Gentry and C. W. Nelch are the principal incorporators.

Columbus, Ohio—The Central West Coal and Lumber Co., of Columbus, has increased its authorized capital from $100,000 to $250,000, in order to acquire additional mining property in the Hocking Valley and Pomeroy Bend fields. J. S. McVey is president.

Whitesburg, Ky.—The Wells-Elkhorn Coal Co., recently incorporated by A. M. Kelly, J. S. Fitzgerald and L. S. Wilson, has filed notice with the Secretary of State of an increase in its capitalization from $75,000 to $300,000 to provide for general business expansion.

Little Rock, Ark.—The North Spadra Coal Co. has filed articles of incorporation with a capital of $25,000 to engage in general coal-mining operations in the Little Rock district. W. R. Eustice is president, L. Werner is vice president and P. D. McKinnon is secretary-treasurer.

Chicago, Ill.—The Chicago Pneumatic Tool Co. has moved its Milwaukee office from Room 1305, Majestic Building, to Room 1418 in the same building, where more convenient quarters necessitated by the growing business of the company in this district have been obtained.

New York, N. Y.—The A. P. Green Fire Brick Co., of Mexico, Mo., has opened an eastern district sales office in New York City at 30 Church St. Howard C. Thayer, formerly field mechanical engineer for the J. G. White Engineering Corporation at U. S. Nitrate Plant No. 2, is in charge.

Buffalo, N. Y.—Weston & Dodson, coal miners and shippers at Bethlehem, Penn., will locate a branch office here under the management of H. J. Welch, formerly with the Philadelphia & Reading Coal and Iron Co. here. Better control of the firm's Canadian trade is the principal object.

Buffalo, N. Y.—The Penn Canadian Fuel Co. has been organized with principal office in Toronto. B. M. Bremner, of that city, will be managing director. Members of the Weaver Coal Co., of Buffalo, are largely interested in the new organization. A general rail and water coal business will be done.

Columbus, Ohio—The Ohio Board of Administration will soon place contracts for approximately 20,000 tons of Hocking mine-run to be used at the various institutions of the state for the remainder of the fiscal year up to July 1. The H. W. Jenkins Coal Co. was the low bidder at $1.75 at the mines.

Charleston, W. Va.—J. M. Magee and other business men of Pittsburgh have organized the Allegheny Western Mining Co. with an authorized capital of $100,000 to engage in the mining business. The incorporators are J. M. Magee, A. G. Wells, A. B. Coleman, W. St. Clair Childs and Simon Patterson, all of Pittsburgh.

Webster Springs, W. Va.—The Webster Smokeless Coal Co. has filed articles of incorporation with a capital of $150,000 to engage in the development of coal properties in the Webster Springs district. L. C. Anderson, Welch, W. Va.; J. E. Anderson, Cowen, W. Va.; and E. H. Morton, Webster Springs, are the incorporators.

Zanesville, Ohio—The authorized capital of the Kehota Mining Co. has been increased from $1,000,000 to $2,000,000. The concern has developed several large stripping operations and holds other lands to be developed later. The sales end of the business is carried on by the Pittsburgh & Bessemer Coal Co., of Columbus.

Buffalo, N. Y.—The Peabody Coal Co., of Chicago, has taken offices in the Marine Bank Building and placed them in charge of H. P. McCue, for some time located in Pittsburgh as the assistant fuel controller of Canada. The plan is to concentrate the Canadian trade in the one office, both with Pennsylvania and western mines.

Huntington, W. Va.—Huntington citizens are planning for the development of coal lands near Pikesville, in Pike County, Kentucky, and have organized the Pike Coal Co. with an authorized capital of $10,000. The incorporators of the new company are G. W. Pyle, B. N. Pyle, H. C. Simpson, J. F. Vass, E. I. Hofmier, all of Huntington.

New York, N. Y.—During the year ended Dec. 31, 1918, the New York, New Haven & Hartford R. R. carried over its lines 4,030,863 tons of anthracite coal, an increase of 784,520 tons over the previous year; 5,707,299 tons of bituminous, an increase of 1,130,693 tons over the previous year, and 218,057 tons of coke, an increase of 64,525 tons over the previous year.

Gadsden, Ala.—The Blount Mountain Coal and Iron Co. has been incorporated with a capital of $2,000,000 by Chicago interests. It is understood that plans are now in process of formation for the development of a tract comprising approximately 30,000 acres of coal and iron properties in the vicinity of Gadsden. J. J. Burns is president; F. W. Rehbock, vice-president, and A. Fink, secretary-treasurer, all of Chicago, Ill.

Birmingham, Ala.—It is reported that the properties of the Warrior-Pratt Coal Co., at Porter, in the western part of Jefferson County, have been leased to the Sheffield Company, with furnaces located at Sheffield, Ala., and large ore mines in the Russellville district. The company also has beehive coke ovens in Walker County not far distant from the leased properties, which will be available for coking the output of the mines.

Columbus, Ohio—City Purchasing Agent Guthke opened bids Apr. 7 for approximately 7000 tons of nut, pea and slack for the garbage and refuse plants, the municipal light plant and the waterworks department. The Maynard Coal Co. bid $1.53 for Pomeroy Bend coal, guaranteeing 12,200 B.t.u. and taking a discount or premium as the case may be. The contract was awarded to the Maynard Coal Co. The Fletcher-Williams Coal Co. bid $1.44 for Hocking nut, pea and slack.

Louisville, Ky.—A license ordinance recently introduced before the City Council, and which would have taxed all coal brokers, retailers, salesmen, etc., the retailers paying on the basis of volume done per year, was killed in the city council last week, a substitute ordinance being introduced which left the coal men out. This ordinance was framed for the purpose of raising revenue sufficient to meet the loss that will result in city revenue from national prohibition.

Buffalo, N. Y.—The Buffalo office of the Century Coal and Coke Co., of Montreal, announces the consolidation of that company with four Canadian companies—the Quebec Coal and Dock Co., the Toronto Coal and Dock Co., the Port Colborne Coal and Dock Co. and the Northern Dock and Coal Co., of Sault Ste. Marie, Ont.—with capital of $2,500,000, under the name of the Century Coal Co., Ltd. The principal office will be in Montreal as formerly. The leading organizers were Fred McCourt, Dr. W. L. McDougald and Harry F. Butler, of the Century company.

New York, N. Y.—The Railway and Power Equipment Co., Woolworth Building, New York, is planning increased scope of operation. With this in mind it has been incorporated in Delaware with a capital stock of $5,000,000, $3,000,000 common, $2,000,000 7 per cent. cumulative preferred. In addition to the interests of Charles F. Johnson, who has been carrying on the business for about 20 years, it has taken in other interests. Its new work is planned to include engineering and equipment work in any way connected with power, railroads, industrial establishments and contracting in all parts of the world.

St. Louis, Mo.—Because of the unusual heavy coal-shipping conditions which have developed on the Illinois Central R. R. between southern Illinois coal fields and St. Louis, that company has constructed a four-mile double-track extension on this division between Belleville and Wilderman. It is estimated that at least 90 per cent. of southern Illinois coal which is billed to St. Louis is routed over this division.

An organization has been perfected in Franklin County to be known as the Franklin County Mine Examiners' Safety First Association, the object of which is to better mining conditions and urge safety first measures in mining. Resolutions dealing with mining methods were drafted and will be presented to the State Department of Mines and Minerals.

Chicago, Ill.—The American Steam Conveyor Corporation announces the appointment of Charles H. Florandin, formerly of the National Electric and Welding Co., New York, as general manager of its eastern territory with headquarters at the New York office, 110 West 40th St. Mr. Florandin, who assumes charge of his new duties May 1, was born in France and received his technical education at the famous Lycee de Marseilles. He is an engineer by profession and upon coming to the United States did important work with the Brooklyn City Railway Co. in the early days when the road was being electrified. After five years' service with this company, he joined the C & C Electric Co., New York, where he held a responsible position with them for many years.

New York, N. Y.—The Railway and Power Equipment Co., Woolworth Building, New York, has received an inquiry from Belgium for $200,000 worth of machine tools, including lathes, planers, shapers, turning and boring machines, slotters, radial drills, steam hammers, shears, punches and shears, machinery for manufacturing springs, four 16-ton traveling cranes. It also has the following inquiries: 120,000 tons new steel rails for a French colony; five tons of portable track for France; electric power and lighting machinery for Japan; slotters, hammers, presses, cranes, locomotives, for Bombay, India; railway, mining, sugar plantation and factory equipment for Panama; air compressors for Chile; derricks and electrical machinery for Hong Kong, China; contractors' supplies, machinery and equipment for France; machine tools and hammers for England; railroad equipment for Spain; machinery and tools for Antofagasta, South America; a large quantity of electric motors for Bombay, India; machinery and tools for Brazil; railway equipment and machinery for Argentina; three new steam locomotives for Japan; forty pairs of steel car trucks for electric railways for Italy.

MARKET DEPARTMENT

EDITED BY ALEX MOSS

Weekly Review

Slight Improvement in Bituminous—Production Still Dropping—Better Buying Demand Looked For—Anthracite Situation Is Decidedly Better—Small Sizes Scarce and Prices Being Maintained at Former Levels

ALL things considered, the bituminous coal market shows an improvement over the previous week. Conditions are far from satisfactory, however, the general lack of interest on the part of buyers being still in evidence. The soft-coal mines continue to work on a restricted basis, and the output from the respective operations is merely sufficient to meet the orders on hand. During the week ended Apr. 5 the bituminous mines of the country produced 7,005,000 net tons of coal, which is 455,000 net tons below the production for the week ended Mar. 29 and 2,280,000 net tons below the output for the week of Apr. 6, 1918.

Little progress has been made during the past week in the railroad fuel controversy. It has been announced that the railroad employees are to receive another increase in wages. As practically all the roads are short of funds, this added financial burden will undoubtedly lead to a substantial increase in freight rates. The coal industry is anticipating a stronger market from now on, as many consumers will purchase their coal before the proposed advances go into effect. Quite an active demand is evident for the higher grades of soft coal and prices are being maintained at or near the former Government maximums.

There is a decidedly encouraging improvement in the anthracite situation. Demand has become stronger, and all branches of the industry appear to be busier than they have been for some time. Shipments of anthracite to New England have become stronger as the result of a reduction in waterborne freight rates. Pea coal and the smaller sizes are in much better demand. All of these coals are tightening, and quotations that were being shaded are nearly back to normal.

The output of anthracite during the week ended Apr. 5 is estimated at 1,272,000 net tons, approximately 160,000 net tons below the output recorded during the week preceding and 600,000 net tons lower than the production of the week of Apr. 6, 1918.

WEEKLY COAL PRODUCTION

The observance of Apr. 1 as a miners' holiday tended still further to reduce production of bituminous coal during the week ended Apr. 5, the output being estimated at 7,005,000 net tons. This production is 455,000 net tons below the output the week of Mar. 29 and 2,280,000 net tons below the production for the week of Apr. 6, 1918. The daily average production during the week ended Apr. 5 is estimated at 1,167,000 net tons as compared with 1,382,000 net tons for the calendar year to date, and 1,763,000 net tons for the same period of last year. Estimates for the calendar year to date place the output at 113,329,000 net tons as compared with 144,591,000 net tons for the period Jan. 1 to Apr. 6, 1918.

Production of anthracite in the United States during the week ended Apr. 5 is estimated at 1,272,000 net tons, and is approximately 160,000 net tons below the output recorded during the week preceding. Compared with the corresponding week of last year the current weekly output falls approximately 600,000 tons. The total production of anthracite for the period Jan. 1 to Apr. 5 is estimated at 18,943,000 net tons, as compared with 25,563,000 net tons during the same period of 1918. The daily average for this calendar year to date is 231,000 net tons and falls 81,000 net tons below the daily average of last year, estimated at 312,000 net tons.

The carriers' reports for the week ended Apr. 5 show a decrease in loading in all fields with the exception of western Pennsylvania and the southern West Virginia fields. Decreases which occurred in other fields, with the exception of Ohio and the district including Illinois, Indiana and western Kentucky, were slight, while the decreases in the two fields mentioned were large.

Shipment of bituminous coal from the tidewater harbors to all points during the week ended Apr. 5 is estimated at 470,729 net tons, and while in excess of the tonnage moved during the week ended Mar. 29, estimated at 402,126 net tons, falls considerably behind the movement during the corresponding week of 1918, when the tonnage equaled 698,930 net tons. Improvement in the current week's shipments over the week preceding occurred at all harbors—New York making the greatest gain.

Shipments to New England by tidewater during the week ended Apr. 5 are estimated at 120,162 net tons as compared with 89,166 net tons during the week of Mar. 29. The current week's shipments, however, fall approximately 110,000 net tons below that for the week of Apr. 6, 1918, estimated at 229,278 net tons. Shipments to New England by rail during the current week were not reported.

The production of beehive coke in the United States during the week ended Apr. 5 is estimated at 369,807 net tons as compared with 362,283 net tons during the week preceding and 568,651 net tons during the corresponding week of 1918. During the current week considerable increase occurred in Colorado, Oklahoma and New Mexico compared with the week ended Mar. 29, and is approximately the same as produced in these states during the week ended Apr. 6, 1918. In all other states production was considerably lower than that reported during the corresponding week of last year. The daily average per working day during the week ended Apr. 5 is estimated at 61,635 net tons, as against 77,392 net tons, daily average for the year to date, and 93,547 net tons for the same period for 1918. The total production for the period Jan. 1 to Apr. 6 for this year is estimated at 6,346,135 net tons, and falls approximately one and one-quarter million net tons below the output of last year.

BUSINESS OPINIONS

The Iron Age—The price-fixing wrangle at Washington has halted business in iron and steel. While ostensibly some development from the repeated conferences between the heads of the Industrial Board and the Railroad Administration is awaited, the belief is widespread that confidence in cooperative price maintenance has been shattered. Pig-iron output was 3,090,243 gross tons in March, or 99,685 tons a day, against 2,940,168 tons in February, or 105,006 tons a day. Furnaces active on April 1 were capable of producing 93,165 tons a day, against 101,475 tons a day as the rated capacity active on March 1. Since Dec. 1, 94 furnaces have been blown out.

American Wool and Cotton Reporter—Government auctions and the prospects of the domestic clip are prominent features in the Boston wool market. There is also considerable interest in the London sales. It is expected that at the auctions this week prices will be stronger than ever before. News of the good prices paid at the London sales for wools have had a very strengthening effect on the wool trade in this country. A little more inquiry has been in evidence in the cotton market during the week under review, but actual business with the mills has not increased materially.

Bradstreet's—Ordinary distributive trade stimulated by spring influences, perfect winter wheat crop conditions, extraordinary prices present and prospective for farm produce, past excellent industrial and agricultural earnings and the return of hundreds of thousands of soldiers to private life with money in their pockets, shows further expansion, despite inclement weather and bad roads in some sections, buying from wholesalers for fall is rather more confident and while there are evidences of conservatism due to price reduction talk the reductions so far made are not up to expectations. As for some time past consumptive demand seems to single out lines which have been under the ban of war necessity.

Dry Goods Economist—The call for merchandise is perhaps more insistent in connection with goods whereof the production period is close to that of consumption, such as women's, misses' and children's wear, dress accessories, fancy goods, notions, etc. Nevertheless, in all of the piece goods lines there are evidences of an increased willingness to operate on the part of buyers, due, no doubt, to the reductions in price which have taken place. Raw materials also continue high, cotton in particular having advanced 200 points during the last two weeks. At Government auctions the better grades of wool have brought prices well above the Government's minimum figure.

Marshall Field & Co.—Current wholesale distribution of dry goods is nearly up to the large volume of the corresponding week of 1918. Retail business continues excellent and a great many more merchants were in the market. Road sales for immediate delivery were larger, compared with the same period last year. Orders for fall delivery are being placed in excellent volume, which indicates that merchants now have confidence in the stability of prices named for fall merchandise. Collections were normal.

Atlantic Seaboard

BOSTON

Shippers still short of orders for April and May. Only scattering sales. Higher grades firm all-rail. Railroad fuel still a storm center. A depressing factor in prices of higher volatiles. Light production and conservative selling characteristic of central Pennsylvania. Hampton Roads tonnage very light. Shipping Board rates reduced. Delivered prices named. Large buyers tempering the market. Flirting with oil. Anthracite shipments slow starting. Sundry difficulties. Demand increasing. Retail deliveries show marked improvement.

Bituminous—The market here continues without material change. There is the same dullness and the same general lack of interest on the part of buyers that has been usual for the past six weeks. Through the lack of orders for spot shipment most of the operators are getting out about 50 per cent. of the usual tonnage, and there is little chance that New England will be the means of boosting this any for some weeks to come. There is a good deal of talk in trade circles about the interruptions that are likely to take place in mining and transportation in the fall and winter, but the mild season we have just gone through and the high water that has helped out so many manufacturers have only served to postpone the time for anything like active buying in this territory. All sections are being carefully combed for orders, but reports agree that for May as well as April there will be only a light business.

A few mill buyers are placing orders for limited tonnages for delivery over a period of five or six months, but in the aggregate the volume is small and is not particularly significant. Aside from the few contracts that continue to be made on specialties, there are only scattering sales. There is more faith in the market than was the case a month ago; there is also less disposition to buy the lower-priced medium grades. There is more and more insistence on coals of recognized value and in another two months it is quite likely these will be well sold up.

Prices on the quality coals are being firmly maintained, especially all-rail, and few concessions are heard. This is the wiser course on the part of selling agents, for not infrequently it happens that the higher price will sell coal when other conditions are not so favorable. The weak spot is in the Fairmont district where the railroads seem to be having pretty much their own way. It is only natural that coals in that region will be the last to react to any improved demand, especially in this territory where consumers are so well stocked that for a long time to come their interest will be only in the low-volatile grades from other districts.

Proposals have been submitted the past week to the New Haven road, and on the 17th inst. bids will be received on locomotive fuel for the Boston & Maine. The latter is not as accessible to the Fairmont district as the New Haven, and for that reason is not likely to buy on quite so low a range of prices. A small block of high volatile from central Pennsylvania was rumored to have been bought by the Boston & Maine for April-May delivery at a price very close to $2 per net at the mines. Practically every house in the trade has been invited to submit prices for deliveries over any period to Apr. 1, 1920, although no purchase is likely to be made of any save operators, so great is the pressure from Washington to buy only at first-hand. So long as low prices are quoted on railroad fuel there is not likely to be any marked improvement in buying sentiment.

Many of the larger buyers have been accustomed to wait the results of railroad buying, although it is by no means clear this present season whether railroad purchases will be a sufficient guide. One-third of the bituminous that comes here is of course used by the railroads, and a determined effort is being made to arrange for a large portion of their tonnage to come by the all-rail route. Undoubtedly the railroads will have their way, and once their requirements are arranged for there will be some effect on the volume of commercial coal that it is sought also to bring to this market through all-rail channels. Today the Railroad Administration is certainly a depressing factor: it remains to be seen what will be the effect of purchases it is now proposed to make. The trade is following the controversy with much interest, but the opinion seems to be that price-fixing is now out of the question.

So long, however, as operators in Central Pennsylvania adhere to their policy of light production and conservative selling there are likely to be few weak spots among the coals that most steam-users want to buy. On some of the medium coals there are still prices down to $2.60@2.75 for spot shipment, but there are no sales of any consequence. What market there is seems to show a pronounced tendency toward the higher grades.

Hampton Roads tonnage is also very light. In one day recently there were only five bottoms entered at the piers to load, and practically every agency has heavy accumulations at all the terminals. The export business seems mostly a mirage, unless and until suitable ships are forthcoming at rates that will enable American coals to compete. Aside from the few contracts that shippers have been able to make this season there is little doing on Pocahontas and New River in New England. The Shipping Board has now reduced rates another 50c. on steamers under its operation, making the new rate from Hampton Roads to Boston $2, or $1.75 to Providence. Outside barges are also on a $2 basis, although there have been rumors of a rate as low as $1.75, Norfolk to Boston. Even on this latter rate the smokeless coals are likely to be confined pretty closely to an area within a score of miles or so of the tidewater distributing point.

Certain of the rehandling factors here have made a tentative price of $7.90 per gross ton f.o.b. cars Boston for inland delivery through the year to April next. This makes the cost at Lowell, Mass., for instance, very close to $9, or nearly $1.50 per ton more than high-grade Pennsylvania coals at $3.10 per net ton at the mines. It is doubtful whether the large textiles will make any very comprehensive purchases on the basis referred to. Purchasing agents are tempering the market, and it is still too early to get a line on their probable procedure. Too often have they seen Hampton Roads prices drop between April and July to get much interested in buying at this stage. Then, too, there are several who want to know more about fuel oil. There is every prospect that very large preparations will soon be apparent for handling oil at various points on tidewater.

Bituminous prices at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net ton, as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.80@3.35
Philadelphia, gross tons	4.20@4.90	5.00@5.40
New York, gross tons	4.50@5.25	5.35@5.80
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.65

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.69@5.14 f.o.b. Norfolk and Newport News, Va., for spot coal. Alongside Boston the present gross ton range would be $7.15@$8.10.

Season prices have been made at $7.90 on cars Boston, for inland delivery.

Anthracite—Somewhat contrary to trade expectation anthracite shipments both all-rail and by water have started very slowly. The mines are now on a full-time basis, but not yet have domestic sizes reached the piers in customary spring volume. Certain sizes are in short supply and the Railroad Administration has further hampered movement by changing instructions as to the type of cars furnished. Port Reading loading is still insisted upon for Philadelphia & Reading railway barges notwithstanding all the delays and hindrances that are plain even to the casual observer. A few barges are loading at Philadelphia, these having come out of the repair yard, and there the customary service is given including the proper screening of the coal. The independent operators are finding it hard to interest retail dealers in their output, for many of the latter have memories of service received in 1917 and 1919.

It is clear, however, that the demand is increasing. Every week that passes without usual spring loadings is just so much handicap on shipments later on. The publicity given to conditions in the anthracite region is causing a much better request from householders, and notwithstanding the present scale of retail prices the dealers in most towns have all the business they can swing with their present stocks and the rate that shipments are now coming forward.

NEW YORK

Anthracite situation shows improvement and dealers look for a brisk spring and summer. Demand is better and consumers show a desire to place orders for immediate delivery. Shipments from local docks delayed by marine strike. Some operators sold up until June 1. More inquiries for bituminous and prospects are encouraging.

Anthracite—Business at this Tidewater market shows a betterment, while reports from inland territory indicate that trade is picking up. There has been an improvement in local conditions which is encouraging. Demand has become stronger and dealers look for an active market as soon as the marine strike is settled. In the meantime all branches of the industry appear to be busier than they were a couple of weeks back. Consumers are placing their orders with the retailers and the latter, if they have the coal in their yards, are making immediate deliveries. This means additional orders for the wholesale dealer.

The reports from the coal fields show that the operators are looking ahead, as orders have been given in many instances for steadier operation of the mines. Some mine owners have orders ahead to keep them busy for a month, while it is claimed some of the smaller operators have sufficient orders for all sizes to keep their plants going full speed until June 1.

Stocks at the loading piers in this harbor show a steady increase and coal is moving freely notwithstanding the harbor tie-up. Some of the large companies have no difficulty in taking care of their customers, either on water deliveries or by rail.

Canadian dealers are sending many orders and additional inquiries to the local trade, with requests for hurry shipments. Similar indications of an active demand come from the west, where it is said consumers are not taking any chances of being found without sufficient anthracite to see them through next winter. The consensus of opinion among the trade is that for the next several months the industry will be active in all branches.

The improvement in the line trade has been decidedly noticeable. Wholesalers have many orders on their books calling for early delivery. Shipments to New England and to points along Long Island Sound have become stronger because of the reduction in water freight rates by some concerns.

Retail dealers report a much heavier receipt of orders from consumers than has been the rule for the past few weeks, but they attribute a great deal of the rush to the fear of consumers that because of the marine strike it would be wise for them to place their orders now rather than wait until later in the season, when because of the demand all over the country there might be a shortage of coal. It also indicates a desire on the part of the consumers to save the May 1 advance.

Pea coal and the smaller sizes are in much better shape than they were a week ago. All of these coals are tightening and quotations which were being shaded are nearly back to normal.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	5.85	7.70
Stove	6.10	7.95
Chestnut	6.20	8.05
Pea	4.80	6.55
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—There has been an improvement in buying here but deliveries have been slow on account of the labor trouble in the harbor. Buyers are in a better frame of mind regarding prices and stocks are considerably reduced. The strike which is now in its seventh week has taken just that many weeks' supply of coal from the local market and consequently bins are nearly bare.

Indications point to a busy market as soon as there is a settlement between the private boat owners and their workers. At present all proposals are off and both sides say they are in the fight to a finish. In the meantime users of coal are running short and it is possible that some of the industries in the Metropolitan district that depend entirely upon receiving their coal supply by water may have to curtail operations or haul the coal from nearby railroad sidings.

Wholesale dealers are pleased by the increase in the number of inquiries being received. Buyers, while interested as usual in the quotations, appear to be just as much if not more interested in the quality of coal to be shipped.

Embargoes on individual shippers have kept stocks at the docks well within the necessary limits, which has enabled all shippers to keep sufficient coal on hand to take care of the necessary requirements of their customers. At the docks on Apr. 9 there were 5170 cars of bituminous standing as compared with 4730 cars a week previous, while the number of cars enroute was 2978 as against 3280 on Apr. 2.

The mines are being operating on about a half-time basis but this seems sufficient to take care of immediate wants. So far there has not been a tendency to stock up but shippers expect that consumers will soon come into the market for larger and more frequent deliveries

The fuel supply for the railroads and the price question continue to agitate the trade. Producers fail to see any reason why the railroads should not purchase their supply of coal at the same price as is charged the industrial or any other consumer.

Quotations for coal for spot delivery or on contract show several changes from those of last week, and are as follows:

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.80 to 3.10	2.95 to 3.25
Clearfield County (good grades)	2.65 to 2.95	2.80 to 2.95
Reynoldsville	2.65 to 2.85	2.85 to 2.95
Quemahoning	2.75 to 2.95	2.95 to 3.10
Somerset County (best grades)	2.75 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.25 to 2.50	2.50 to 2.75
Western Maryland	2.25 to 2.75	2.50 to 2.75
Fairmont	2.10 to 2.35	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.35 to 2.40	2.35 to 2.60
Westmoreland ¾-in.	2.60 to 2.75	2.65 to 2.75
Westmoreland run-of-mine	2.40 to 2.65	2.40 to 2.65

PHILADELPHIA

Anthracite trade improved. Mines on full working time. Dealers buying heavily. Retailers using advertising methods. Spring business fair, with public in no hurry to buy. Some suggestions of labor trouble. Summer outlook not promising. Stove and nut in good demand, but pea difficult to move. Retail cash plan fails. Bituminous quiet. Good coals in demand. Railroads buying little fuel pending price discussion. Some commercial contracting.

Anthracite—The improvement in market conditions is probably best shown by the change in the working schedules at the collieries. A few weeks ago the big companies were working three days a week and storing some of the production at that. Now they are planning for six full working days a week for the entire month, or at least until some impression can be made on the mass of business that has accumulated so rapidly. Of course, the sudden and changed conditions came about through the announcement on the last day of last week that the Governor of Pennsylvania had been convinced that the operators were justified in the plan of advancing prices 10c. per ton for five months commencing May 1.

Undoubtedly the dealers are buying more coal than they are selling, and it may be that the present rush of business is not as substantial as appears now. Many retailers report receiving only a fair number of orders and that they call for a smaller tonnage than in former years. They claim their customers are evidently basing their supposed requirements on the past winter's consumption, which in all cases was far below normal.

A number of shippers report having about sold their output of egg, stove and chestnut for the month of April, and there is no doubt of it. It is also quite possible that the dealers will be busier in May than during the present month. Talking with several of the largest operators we learn that the prospects, at least up to the middle of June, are good. We are unable, however, to find any in the trade who predict anything but a very dull summer.

Even the smaller operators, those with high-class coal especially, are apparently taking a more optimistic view of market conditions and several have ceased to actively canvass the trade for orders for shipment of family sizes this month. Pea, though, is troublesome to all and will continue to be so until some change is made in the price. Stove and chestnut at a cost of $1.50 and $1.60 are the more economical household sizes, and the public knows it and is accordingly passing pea by.

The large companies are holding firmly to their $4.80 price and storing heavy tonnages of this size. We hear of several of the smaller operators cutting the price on pea, yet without making substantial sales. Pea coal was never bought heavily in the market during the spring months, even when prices were much lower, and it will be interesting to watch developments, for we cannot see now how six days' production can be cared for. The dealers generally realize that something must be done by the operators later in the season to move this size and are buying sparingly, as they believe they may be able later to stock up on this size at a more favorable price. Locally stove coal has the call just now, and while few need business for egg and nut, it is stove that is in the shortest supply in the yards.

The steam trade is being well taken care of now. With the collieries working the entire week the big companies are beginning to receive sufficient buckwheat and rice to meet the current demand, which up to the past week was somewhat short and necessitated taking coal out of storage. One other result of this increased production has naturally been a still further accumulation of barley coal, which is now going into the storage yards in greater volume than ever.

Many of the larger companies are still working on their contracts for steam coal and while many of them have been signed, they have a great number still outstanding. The consumers are in no hurry whatever to sign, as with buckwheat at a price of $3.40 many of them are considering the advisability of turning to bituminous coal, which can now be had on contract terms quite favorable.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	5.85	7.70	Rice	2.75	3.65
Stove	6.10	7.95	Boiler	2.50	3.50
Nut	6.20	8.05	Barley	2.25	3.15
Pea	4.80	6.40			

Bituminous—There is no change of any moment in the soft coal trade. All mines are working on a restricted basis, just turning out sufficient coal to meet the orders in hand. The only real demand is for the better coals. The call for these grades still continues actively from New England territory.

Producers receive numerous inquiries from consumers asking in regard to contracts, but in proportion to the amount of business closed it would appear that the consumer is merely "shopping around" in an endeavor to find out the state of the price market. In the cases of contracts that have been closed very few of the buyers are taking the amount of coal asked for in the contracts, as the state of industry in this district is as yet far from satisfactory, although the greatest optimism is expressed that a few months will see a general resumption in all lines.

Prices remain firm and it is only in occasional instances that one hears of any recession. The following table gives a fairly accurate idea of the price situation:

Georges Creek Big Vein	$3.00 @ $3.10
South Fork Miller Vein	2.95 @ 3.10
Clearfield (ordinary)	2.70 @ 2.90
Somerset (ordinary)	2.60 @ 2.80
Fairmont lump (ordinary)	2.40 @ 2.50
Fairmont mine-run	2.20 @ 2.35
Fairmont slack	2.10 @ 2.25

BALTIMORE

Bituminous market remains spotty, with contract making light and offerings in open purchasing considerably off the general contracting price. Gas coals particularly weak. Anthracite men busy and spring orders heavy.

Bituminous—Soft coal is spotty and the tendency is toward weakness. The local market has little to offer in the shape of encouragement for immediate trading. The future holds out great promise, however, and the faith of the coal men in a coming business revival and for a big export when more bottoms are available remains unshattered. While quotations on good coals awheel continue on a mine basis of from 30 to 70 cents off the old Government maximum rates in many cases, there is strong adherence to these prices when quoting on contract. Operators of mines where the better grades of coal are produced refuse to consider any large volume of future business at less than the old maximums, and already some of the mine owners are asking for more.

Gas coals are particularly weak, due to the fact that many war industries that had used the fuel are now out of the market. At times these coals can be bought below the $2 mark, mine basis. Reports from western Maryland and West Virginia operations are to the effect that the daily output is running only to about 40 to 50 per cent. of capacity, and that the tendency is to concentrate on mines producing better grades of coal. The Georges Creek and Upper Potomac regions, in which railroad fuel orders have in the past amounted to 2,000,000 tons annually, are just now barely running.

Anthracite—Hard coal dealers are enjoying a period of happiness. The cut of 40 cents a ton in the winter schedule and of 25 cents additional for ten-day cash payments, has spurred the public to order their coal. Many dealers are rushed, and there is a belief that a large volume of orders will go on the books during April and May. The local outlook—should there be no further freight-rate increase—is that the present retail price list will be maintained until July 1, despite the plan to advance wholesale prices 10 cents a month dating from May 1. In July the retail price will probably be advanced 25 cents a ton to cover advances, and it may be that this price will be the ruling price for next fall and winter. Such a schedule would bring coal to 15 cents per ton cheaper than last winter. The city of Baltimore has asked for bids on 11,000 tons of anthracite, the bids to be opened Apr. 23. Little contracting is reported.

Lake Markets

PITTSBURGH

Operations slightly under 50 per cent. Pittsburgh market holds relatively well. High-grade byproduct and gas coals firm.

Coal-mining operations in the entire Pittsburgh district are showing an average of a trifle under 50 per cent., which is an improvement over operations at some earlier times in the year. The market is hardly as strong as it was a week or a fortnight ago, but it has softened very little. Considering the general unsettlement in the coal trade of the country, and the warm controversy at Washington over prices for railroad fuel and the manner in which purchases should be made, the Pittsburgh coal market is really showing a remarkable degree of strength. This is the more noteworthy by reason of the fact that there is by no means complete coöperation between the producers. For instance, some prominent independent operators openly state that they do not intend to be guided, in their sales policy, by what the leading interest desires or states to be its own policy, while some operators, particularly in the Panhandle district, have freely cut prices to the extent necessary to secure the volume of business they desired.

With all this, the Pittsburgh market maintains a moderately even keel, while as to high-grade coking and gas coal it is absolutely firm at $2.35 for mine-run. Operators admit that these prices may possibly yield in time, but the important fact is that even up to this time they have not yielded. The railroads have not bought a great deal of coal in the Pittsburgh district, and on what they have bought they have paid what should be considered high prices in view of reports from Washington as to the low prices at which coal has been picked up by the Railroad Administration. For Panhandle steam coal, for instance, the Pennsylvania lines are understood to have paid $2.15. There is no regularly quotable market on domestic coal, as transactions are light, and besides this there is a wide range in the quality of coal desired by different retail dealers, some preferring to handle high-grade gas coal while others take decidedly indifferent steam coal, analysis being practically no consideration.

Some leading operators, particularly those with the better grades of coal, are desirous that the old fashion of quoting "Pittsburgh coal" at one price only should be absolutely discarded, and that prices should be quoted according to quality and character. The high-grade coking and gas coals, it is pointed out, ought to be conserved for their proper uses and should command a higher price than ordinary steam coal, while even in steam coal there is quite a range of quality.

We quote the market as follows: Good grade byproduct coal, mine-run, $2.35; high-grade gas coal, mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in.; $2.60@2.70; slack, $2.25@2.35; steam coal, slack, $2@2.10; mine-run, $2@2.35, all net ton at mine, Pittsburgh district. Some high sulphur Connellsville coal has been sold at low prices, but that is altogether outside the district.

TORONTO

Coal business continues generally dull. Consumers ordering from hand to mouth. Toronto dealers organize. Office of fuel controller likely to be continued.

The demand for coal both for domestic and industrial uses continues light, from causes previously indicated, and dealers are doing very little business. The situation has been unchanged for some weeks, orders being merely for temporary requirements as a rule. The public has so far shown little disposition to follow the advice of the Fuel Controller and place their orders early, apparently hoping that prices may fall in spite of assurances to the contrary. With the object of promoting friendly relations, avoiding misunderstandings among the trade and keeping in touch with conditions, the local dealers have organized as the Toronto Coal Dealers' Association with Frank Rogers as president; Charles McGill, vice president; and James Hardy, secretary-treasurer. It is considered altogether probable that in view of the petition of the Canadian Associated Coal Dealers to that effect the Government will continue the office of Fuel Controller for another year.

Quotations for short tons are as follows:

Retail:	
Anthracite egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	8.25
Slack	7.25
Domestic lump	10.00
Cannel	13.00
Wholesale f.o.b. cars at destination:	
Three-quarter lump	6.25
Slack	5.25

BUFFALO

Still waiting for a stir. Slight improvement here and there. Government uncertainty does harm. Anthracite to be short again.

Bituminous—The trade goes on much the same. Jobbers get some orders, but as a rule the consumer reports that he has a month's supply or more. When that is gone there must be more buying, so the trade waits for that. It is a long delay, but it may be made so speedily if the car supply should run short. So the jobbers try to make the most of the situation. They find some improvement, but as a rule the situation does not change. It is likely to be midsummer before trade is good. In fact we may be well satisfied if it comes then.

Much uneasiness is shown over the railroad complications. Sales to the roads are few and payment is uncertain. No very satisfactory trade is possible till the roads are in better shape. While the people here do not say the roads should go back to the old management, the idea is that a firmer basis would be reached if something of the sort were ordered. The emergency is past, and if the plan of handling cars as one body were continued the Government control might go. Then an adjustment on a paying basis could be made. It will never happen now.

Bituminous mining is slow. Some mines are running only about two days a week and none can be said to be really active. This increases the cost of the coal and satisfies nobody. For all that, the mining capacity increases slowly, in the face of such poor prospects.

The firm condition of prices continues. That seems to be the last hope of the trade. If price cutting is increased much the situation will become serious. Some reductions are made, but the coal generally is not good. Quotations remain on the basis of $4.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh and No. 8 lump; $4.20 for same mine run or slack; $5.65 for smithing and smokeless; $5.60 to $6.10 for cannel; all per net ton, f.o.b. Buffalo.

Anthracite—The demand increases and the supply falls off. Shippers are saying that a shortage next winter is certain. Consumers will not buy fast enough to keep the mines in full operation, and when the fall rush sets in they cannot be run fast enough to meet the demand. It is time that consumers realized this, but only a few do. Already some of the lake shippers are turning all their receipts to the rail and will load no more vessels till navigation opens. The prospect of no sailing till late this month continues.

The prices of anthracite to the Buffalo market remain as follows through April:

	F.o.b. Cars Gross Ton	At Curb Net Ton
Grate	$8.55	$10.25
Egg	8.45	10.20
Stove	8.70	10.10
Chestnut	8.80	10.50
Pea	7.00	9.05
Buckwheat	5.70	7.75

CINCINNATI

Conditions quiet, and no great demand expected in immediate future. Prices being maintained.

The general condition of the coal trade in Cincinnati remains extremely quiet, with the possible exception of the fair demand for steam grades. While the more optimistic dealers describe the market conditions as fair, the majority of them qualify the statement by saying that it is fair, considering all the adverse factors affecting the demand at present, by which they mean the general let-up in industrial pursuits and the early opening of spring, which naturally affects the demand for fuel. Then, too, there is the fact that large quantities of coal were laid in by consumers in the expectation of a severe winter, which failed to materialize, thus leaving coal bins and cellars well stocked. There is every likelihood that this condition will have a serious effect on the demand for domestic grades for the remainder of the spring and summer at least, and that the sales in this branch will be far below normal during the coming season. Prices remain firm, although small producers, in some cases, have taken orders below the market, presumably in order to maintain their organizations.

CLEVELAND

Demand for No. 8 coal for the lake trade is coming out surprisingly strong, and operations in eastern Ohio are rapidly being speeded up. No. 8 ¾-in. lump for lake shipment is holding firm at $2.35 and $2.40 f.o.b. mine, about 25 and 20c. under last year's price, while northern Ohio offerings are as low as $1.90.

Bituminous—Operators in the No. 6 and the No. 8 districts of eastern and southern Ohio evidently are cleaning up their accumulations, for offers of low-grade coal this week have been the most numerous in a long while. Some blocks have been offered at as low as $1.90, and it is believed $1.80 could be done, in a pinch. This is the lowest the bituminous market has sagged since the armistice. High-grade No. 8 ¾-in. lump seems to be plentiful at around $2.20, and some retail dealers claim to have offers of this grade at $2.15 and $2.10. Outside of the block of lake coal that went at $2.35, no more No. 8 ¾-in. lump for the head of the lakes is reported closed. Most No. 8 operators are believed to be holding out for $2.40, though on a large percentage of the early shipments the price is being left for adjustment later.

Operators appear to be completely at sea in regard to railroad buying. That the Railroad Administration will drive a bargain shortly, or rather attempt to drive one, is the general belief. Return of the railroads to their corporate owners is looked for around July 1, and it is assumed that inasmuch as they must be turned back in worse shape physically than they were in when taken over, Railroad Administration officials will seek to offset this partially by low-price contracts for coal and steel rails. Ohio operators are largely dependent upon the railroad fuel business, but appear determined to hold out against a deep cut. A reduction of 20c. in contract railroad fuel is one prediction, and it is the only one hazarded here.

Larger steam-coal users still are flirting with proposals but have not yet done any worth-while buying. Another 30 days, however, will see some fair-sized tonnages contracted for, it is believed. Stock piles are wearing down, and industrial buyers appear only to be awaiting action by the Railroad Administration in order to satisfy themselves as to price. Domestic demand for bituminous, and for anthracite and Pocahontas as well, has faded to virtually nothing. This is to be expected at this time of the year.

Lake Trade—Demand for No. 8 coal for lake shipment has exceeded the hopes of even the most optimistic, and preparations are under way at a number of mines to get on to full-time as soon as possible. By Apr. 20 fully 500,000 tons will have gone over Lake Erie car dumpers, it now appears. Few cargoes, if any, however, will be unloaded at the head of the lakes before May 1. In some quarters there is speculation whether fuel coal put down on the docks last summer will be marked down in price in order to move it. Lake carriers that held winter grain cargoes are being freely moved at Lake Erie ports in order to take on coal cargoes. Insurance rates on coal for the 1919 season have been fixed at 7½c. per 100 tons—the same rate as last season.

Prices of coal, per net ton delivered in Cleveland, are:

Anthracite:	
Egg	$10.85 @ 10.95
Chestnut	11.00 @ 11.15

DETROIT

With buyers indifferent and sales small in volume, the Detroit market is sluggish.

Bituminous—Complaints are still coming from jobbers and wholesalers that the Detroit market is apparently devoid of a buying demand and that all attempts to arouse interest among customers seem to be without result. In view of the attitude of the buyers and the greatly diminished production of the mines, which is a sequence of similar curtailment of business in other markets, jobbers say that matters are seemingly shaping themselves for development of a serious deficiency in bituminous supply before the end of the year.

Unusually large supplies of bituminous in the reserves of manufacturing plants and the storage yards of the retailers constitute the obstacle which the jobbers encounter in their efforts to sell coal. The manufacturing plants are not burning as much coal as under normal conditions. Their reserves contain accumulations of low-grade coal, and jobbers say there seems to be an unwillingness to place further orders until the stock of inferior quality has been consumed. Among the retailers there is an easing off in domestic demand that causes hesitation in buying, particularly as many of the retailers' stocks not only include much low-grade coal but an undesirably large proportion of small coal, such as slack and mine-run.

Quotations on domestic lump, according to the jobbers, are being made at the Fuel Administration prices, though it is admitted that offerings of mine-run and slack have been made on a basis of $1 a ton or more below the figures named by the Government. In negotiations relating to contracts, the Government prices are quoted.

Anthracite—Even the prospect of an advance in price of anthracite on May 1 appears ineffective to stimulate a broad demand from householders. Orders are largely for small quantities sufficient to fill out stocks until warm weather. Retail dealers are striving to encourage early buying. The supply of prepared sizes seems sufficient for the present needs of buyers.

Lake Trade—Vessel owners and shippers of coal by lake routes show no eagerness to get the movement under way. The mines are sending coal to lake loading docks in fair volume and carriers are being loaded, but few or none of these cargoes will be delivered before the last week in April.

COLUMBUS

The Ohio coal trade continues quiet. Contracting is still held in abeyance to wait for price adjustment. Railroads are in the market for a considerable tonnage. Lake trade will be late in opening.

The coal trade in Ohio continues to show little activity in most directions. Because of the lateness of the season the domestic trade is quiet. Steam business is held up because of uncertainty of quotations and there is little prospect of an early opening of the lake trade. Taking it all in all, the industry is marking time and producers as well as shippers are not anxious to go ahead under present unsettled conditions.

The contract situation remains unchanged. Because of the unsettled price for railroad fuel coupled with the uncertainty of the future, purchasers are not inclined to contract for any large tonnage.

As a result comparatively few contracts have been renewed and there are only few that are close to closing. Some of the agreements leave the price blank to be fixed when quotations are settled. Some lake contracts have been made in the same manner. But when it comes to getting down to signing at a certain figure, many difficulties are encountered. It is true that there are quite a few inquiries received and that some quotations are made, but the main volume of business is held up. There is considerable spot coal to be had at less than Government prices and consequently no one is anxious to contract.

The screenings situation is unchanged. Owing to lack of demand there is no market for screenings and an oversupply is reported from every mining field. This is curtailing the production of lump to a large extent.

The lake trade is not showing much signs of opening. There is a belief that it will not open much before May 15, if at that time. Vessel rates and contracts for lake tonnage are still held up because of uncertainty as to price. Reports show that a considerable tonnage is carried over at the head of the lakes and that there is no desire to hurry matters.

Production is rather low in most of the producing areas of the state. Railroad consumption is not large and factories are not getting back to normal business very fast. Consequently, little increase is anticipated in the near future.

LOUISVILLE

Domestic slightly more draggy, but steam grades in better demand. Inquiries coming freely, and a good deal of contract making being done on steam. Prices firm and stronger.

Domestic grades are somewhat draggier than they have been, if such a thing is possible and the retailer is not doing much business. However, the jobbers and producers are managing to keep fairly busy even without any great rush for domestic, as mine-run for steam use is coming better all the time, and the demand for nut and slack should reach a point shortly where it will be a question of disposing of the resulting lump, instead of a question of disposing of the screenings as has been the case for some months.

Inquiries are coming in freely, and operators are now quoting prices on mine-run and nut and slack for annual delivery, although no one is willing to quote much domestic business. It is felt that unless stocking is taken up by the retailer and domestic consumer that the demand for domestic sizes this fall will exceed the supply, resulting in a market higher than a "cat's back." Prices are quoted on domestic for April, May and June delivery, but beyond that period the average producer or jobber will not take chances.

Mines in eastern Kentucky are reported to be operating on a basis of about 65 per cent., with the western Kentucky mines doing a little better than 50 per cent. of full time.

Coal prices are firmer than they have been, although there is some cheap spot coal being heard of at frequent intervals. Good eastern Kentucky egg and lump is selling in many instances at 25c. a ton over other quotations, this being especially true in some sections of the Harlan, Straight Creek and Jellico districts. As closely as can be ascertained, prices for the state, short ton, including brokerage fee to be deducted if sold through jobber, are as follows:

	Eastern Kentucky	Western Kentucky
Block and egg	$2.85@$3.00	$2.60
Run-of-mine	2.20@ 2.50	2.35
Nut and slack	2.00@ 2.10	2.05

Western Kentucky is doing little price cutting, and while stories are heard relative to nut and slack selling at $1.75 to $1.85, investigation generally proves that there was an error somewhere, or that it was some spot coal that had to be disposed of to escape demurrage. Some eastern Kentucky mine-run is selling as low as $1.90, it is reported, but going out and finding it at that price is something else again.

Inquiries are coming in nicely from the southern railroads, the Southern, Seaboard, Louisville & Nashville, Big Four and any number of Georgia and Alabama roads asking prices. Operators and jobbers are sticking mighty close to former maximum Fuel Administration prices in quotations, and there is no prospect whatever for a wholesale cut in prices this spring.

Several producers and jobbers report that business after May 1 will be all that can be desired, and that today business is better than it was last year. Domestic is a problem, but steam should move. Lake inquiry is opening nicely.

BIRMINGHAM

Domestic coal being readily taken, but steam consumers are manifesting little interest in the market, only caring for current needs. Mines operating on a three- and four-day schedule.

There is a decidedly good tone to the domestic coal market in this district, and distributing agencies report that all the available coal of the best grades in being taken readily, and many dealers are signing contracts for their year's supply. Prepared sizes of the lower grades are also coming into favor, and there is a satisfactory demand for the medium-grade coals. Quotations are as follows per net ton mines:

Big Seam lump	$2.90
Carbon Hill lump and nut	3.15
Corona lump and nut	3.40
Montevallo lump	5.00
Cahaba and Black Creek lump and nut	3.85@4.50

Steam buying is confined to small orders, consumers buying in the spot market not taking more than current requirements. Very little contracting is being done as yet. Inquiries are being received by local sales agencies which give promise of resulting in some large export orders being booked in the near future. The last named Government schedules are still ruling on steam coal, which are as follows per net ton mines:

	Mine-run	Prepared	Screenings
Big Seam	$2.45	$2.75	$2.40
Cahaba and Black Creek	3.45	3.75	3.10
Pratt and Corona	2.85	3.05	2.45

Mines in the Birmingham district, aside from one or two producing high-grade domestic coal and some employing convict labor, are working on a schedule of three and four days per week.

Coke

CONNELLSVILLE

Price level unchanged. Open pig-iron market. Continued decrease in coke production.

The coke market is certainly no stronger as to prices, but it is hardly weaker to any material extent. Possibly the market had already got down as low as it could go, with present costs and with the disposition of operators to curtail production if they cannot get their prices. One difficulty is that blast furnaces are going out so rapidly that it is difficult for coke production to decrease fast enough to maintain the pace. Each week seems to show a slight increase in the rate at which furnaces go out of blast. Whatever may be the outcome of the present uncertainty as to how steel prices are to be made in future, whether the Industrial Board will continue its efforts and whether the Railroad Administration will formally indorse reduced prices if made, the pig-iron trade has already established what it is going to do. It is going to have an open market for pig-iron, prices being allowed to go where they will and furnaces going out of blast whenever they cannot sell their output at a profit. The blast furnaces are used to that sort of thing, having always had an open market prior to the war-time price control, while the steel industry has nearly always had a controlled market. Coke operators are in sympathy with this blast furnace policy, and quite naturally, since an open market developed for coke a few days before Government control came off, while pig-iron remained as a controlled market.

The majority of adjustment contracts were settled for April shipments of furnace coke at $4.25, operators having readily yielded from their original demand of $4.50. Odd lots of furnace coke may readily be picked up at $3.75, involving standard grades, off grades not being salable at all except as fuel. Many producers of standard foundry coke are holding at $5.25, while two or three still quote $6 and one has actually sold a few carloads at $7, to consumers unwilling to change brands. Ordinary foundry coke can be picked up at $4.50, which seems to be the absolute minimum. The market is thus quotable as follows: Furnace, $3.75@4.25; foundry, $4.50@6, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Apr. 5 at 172,350 tons, a decrease of 13,310 tons. Production has continually and sharply decreased, as the Connellsville region experiences a greater decrease in demand than the total decrease in coke consumption, because the byproduct ovens have decreased but little.

Buffalo—It is still impossible to sell fine fuel coke in this market and the commercial grades are as dull as ever. Until the furnaces in this district buy ore for the season's use the coke movement will be light. Furnaces are not running at all strong, though they would have started before this but for the hitch in the iron trade. Connellsville shippers quote 72-hour foundry coke at $7 to $7.25, 48-hour furnace at $6.60 and off grades at $6.10. Vessel owners are getting uneasy, but do not dare to start till ore is offered.

Middle Western

GENERAL REVIEW

Certain amount of buying activity leads to slight improvement in Middle West producing districts. Railroad fuel controversy comes in for much criticism. Increased buying anticipated.

A curious situation has developed; operators and jobbers alike are experiencing the same thing—namely, plenty of orders on Monday and Tuesday, and not an order on Wednesday. Exactly what is to account for this is hard to determine, but the consensus of opinion has it that stock piles are running low, and consequently there is a certain amount of buying. Another opinion is that certain interests are feeling uneasy over the labor situation, and are preparing against the eventual disturbance to the market by buying a three to four weeks' supply.

Taking all things into consideration, the market shows an improvement over previous weeks, although conditions are very far from satisfactory. This small improvement is felt by operators in all the coal-producing districts of the Middle West. The district most benefited, as usual, was southern Illinois, but both the Springfield district and northern Illinois report better markets. The Indiana fields have had a little better running time, especially some of the mines on the Vandalia that have secured railroad orders.

There is considerable, in fact much more than considerable, criticism in these parts against Mr. Redfield and his confreres in the railroad fuel question. It will be remembered that Redfield was connected with the "Eastland" disaster, which took place in the Chicago River some years ago, and that this connection of Mr. Redfield's did anything but add to his reputation. It is felt here that the railroad fuel question has become too serious to leave to politicians, and should be decided by a committee who are familar with at least the basic principles of railroading and coal operating.

On Friday, Apr. 11, the papers all published the news that the railroad employees are to receive another raise in their salaries. Inasmuch as practically all of the roads are hard up for funds, this additional burden added to their shoulders will eventually, and perhaps very shortly, result in a substantial increase in rates. The operators and jobbers are anticipating a stronger coal market from now on, as many people will come into the market to purchase coal before the proposed advances go into effect.

CHICAGO

Pocahontas coal in great demand. Steam situation better. Prices holding up well.

Everything points, at this writing, to a complete reinstatement of high-grade eastern coal in this city. It was reported that one dealer on the North Side sold 500 tons of southern Illinois lump, bought last year, at a loss of approximately $1 per ton, in order to make room in his bins for the eastern coal his trade demanded. Pocahontas coal is in great demand, and it is said that the prepared sizes of this fuel are selling at from $3.50 to $3.75 per ton, f.o.b. mines. This coal takes a rate of $2.60 to Chicago, making Pocahontas, on the whole, a pretty expensive fuel. The public are not taking at all well to the increased cost of anthracite fuel, and, as a direct result, there

has been a good market on coke, and on certain high-grade bituminous coals, which can be used as substitutes for hard coal.

The steam situation appears a trifle better, as there is more demand than last week. Prices, considering everything, are remaining remarkably firm, as but few cuts have been reported, and these, as usual, on inferior grades.

Prices per ton are as follows:

ILLINOIS

Southern Illinois	F.o.b. Mines	Rate to Chicago
Franklin, Saline and Williamson Counties, etc.		
Prepared sizes	$2.55@$2.75	$1.55
Mine-run	2.35@ 2.50	1.55
Screenings	1.85@ 2.20	1.55
Central Illinois

MILWAUKEE

Market continues inordinately slow, with little prospect of interesting consumers in supplies for the future. Higher anthracite predicted.

There is absolutely no interest in coal in this part of the country at present, as far as consumers are concerned, and the prospect is that there will be little or no early ordering of fuel supplies by householders. Dealers, however, are naturally concerned as to the future of prices, but they are completely befogged and disinclined to make predictions. It is being advanced that a raise of $1.50 per ton on hard coal is among the possibilities, because of increased mining rates and higher freight charges. The customary advance of 10c. per ton from May to September will combine in the lifting process. On the other hand, it seems to be conceded that bituminous coal will be slightly lower, but no reasons are given for this conclusion except the large stocks on the docks.

Prices for coal and coke of all grades continue unchanged, as follows:

Domestic

Anthracite—	Short Ton
Egg	$12.20
Stove	12.40
Nut	12.50
Pea	11.00
Buckwheat	10.60
Bituminous—	
Pocahontas mine-run	$8.15
Hocking, screened	7.90
Youghiogheny, screened	7.90
Pittsburgh, No. 8, screened	7.90
West Virginia, screened	8.40
Splint, screened	8.40
Kentucky, screened	8.40
Illinois, screened	7.25
Coke—	
Solvay, large sizes	$11.50
Solvay, small sizes	10.25
Smithing	8.40

Steam—

Youghiogheny, Hocking and Pittsburgh	
No. 8, screened	$7.18
No. 8, pile run	6.93
No. 8 screenings	6.68
West Virginia, Kentucky and splint	
Screened	7.68
Pile run	7.43
Screenings	7.18
Illinois and Indiana, screened	6.50
Pile run	6.25
Screenings	6.00
Smithing	7.68

ST. LOUIS

No demand for either steam or domestic. Some little movement of coal to country points, but in a general way the situation is about as quiet as it can be, with little prospect of anything better immediately.

The general spring storage of domestic has not yet started, but there are indications that this will get under way the coming month in pretty fair shape. Little smokeless has come and there is no demand. The demand for smokeless in this territory does not look good for the coming season. As far as Arkansas is concerned, that seems to be even farther away than the smokeless, and it is likely there will be no Arkansas used at all. The price of Arkansas anthracite almost equals the price of Pennsylvania anthracite, and Pennsylvania will always be preferred.

The coke situation is not encouraging. The price is right, but the early buying movement is not under way to the extent that it has made any inroads on the mountainous supply of coke on hand.

In the Standard district some mines are getting one or two days a week on commercial and steam business. There is a slight movement of this coal to the Chicago market, and the railroads are taking some, but in a general way the field is as near shut down as it could possibly be in normal times.

The low prices that prevailed in the Standard field are practically a thing of the past, for from now on the operator must get producing cost or put up an indemnity bond to the mine workers to assure them of their wages. That is practically the ultimatum that has been sent out by Frank Farrington, president of the Mine Workers of Illinois.

In the Mt. Olive district conditions are somewhat better with a greater portion of the tonnage moving north. Prices are being pretty well maintained. This is the only district in southern Illinois that is maintaining the former Government prices.

In the Carterville field of Williamson and Franklin Counties, and also in the Duquoin field, there has been a gradual easing up of orders for domestic sizes, and steam sizes are now in the ascendant. If the demand for domestic sizes continues to ease up it will be only a short time until screenings and the smaller sizes of nut will almost be at a premium. The northern market, however, promises to absorb a good tonnage of early storage coal from this district. If this is the case, the situation will be much easier. Some mines are getting four to five days a week. Others are only getting one or two and some are idle. The railroad tonnage out of this field is light right now, but indications are that this will continue to grow as time goes on.

The prevailing circular at the present time f.o.b. the mines is:

Williamson and Franklin County Association:	Mt. Olive and Staunton		Standard
Lump, egg and nut	$2.75	....	..
Washed Nos. 1 and 2 nut	2.85	....	....
Independent:			
Lump, egg and nut	2.55	2.55 Lump and egg	2.25
Washed Nos. 1 and 2 nut	2.85	.... 2x3 nut	2.00
Mine-run	2.35	2.20	2.00
Screenings	2.20	2.05	1.75
3-in. lump	....	2.30	....
2-in. lump	....	....	2.15
2x6 egg	....	....	2.10

Williamson-Franklin rate to St. Louis is $1.07½; other rates $0.92½.

General Statistics

ANTHRACITE SHIPMENTS FOR MARCH, 1919

The shipments of anthracite for the month of March, as reported to the Anthracite Bureau of Information, amounted to 3,938,908 tons, which exceeded the short month of February, when the shipments were 3,871,932 tons, by only 66,996 tons, or less than 2 per cent.

As compared with March, 1918, when the shipments amounted to 7,276,777 tons, the shipments in March this year showed a decrease of 3,337,869 tons, of 46 per cent. This almost unprecedently low record for March shipments of anthracite was unquestionably due to the holding off of consumers and dealers in making purchases, because of the anticipation of a possible reduction in price on April 1.

The statement issued by the Governor of Pennsylvania Apr. 4 has done much to correct this impression and a decided improvement has already been evinced in business for April, with indications that the demand and shipments will continue to improve during the next few months. The public seems to have taken notice of the warning issued by the United States Fuel Administration that unless consumers and dealers lay in their supplies during the summer months there is serious danger of a shortage of domestic coal next winter.

The shipments by companies were as follows:

	March, 1919	March, 1918	Coal Year, 1918–19	Coal Year, 1917–18
P. & R. Ry	667,229	1,339,051	14,007,057	14,798,496

COAL AGE

Volume 15 New York, April 24, 1919 Number 17

Meeting the Situation

By Floyd W. Parsons

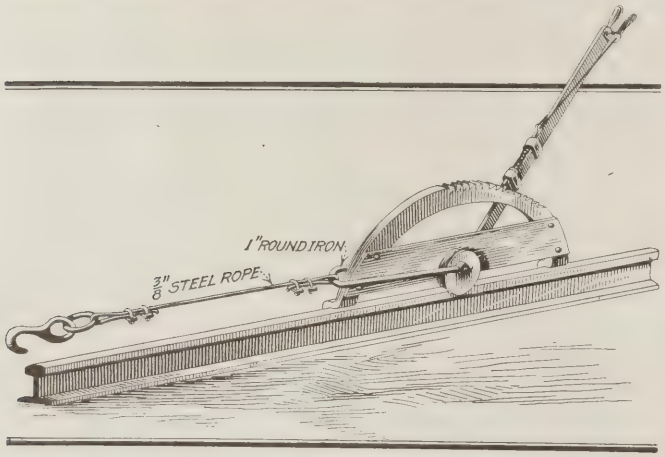
THERE can be no reversion to the standards of industry prevailing before the war, and few people desire that there should be. The so-called common people—those entirely apart from the capitalistic class—are going to get an increasing share of the good things of life. The chief matter of concern is that the changes which are to bring about these new and desirable results shall proceed in orderly fashion along sound economic lines. Our progress toward a new day must be through evolution and not by revolution.

Our minority class of reactionaries might as well try to stem the ocean's tides as to block the coming of a new era. Aside from the cause of justice, they fail to note that unionism has increased to a point where it only has to become political and fuse with the Socialists to hold the balance of power. It is not the workmen but the employers today who are lingering on the shore of doubt. They are mentally unprepared to meet the changing point of view of their employees. They must be educated out of the belief that industry will some day return to the old basis of "hiring and firing." They will have to learn that the manager of a concern is not the exclusive boss.

The one sure way to feed anarchy is to depress wages without regard to the cost of living. Give us a protracted period of unemployment and state Socialism will come in a hurry. There is but one safe road ahead, and that is the highway of full-time production and satisfactory working relations. Never in our history has it been so necessary for the Government to undertake great national projects, and never has Washington been slower in starting. The Nation is waiting for a stimulus, but Uncle Sam refuses to administer the potion.

The solution of the labor problem is not a thing by itself, but a question of complex nature. The war taught us that money alone will not hold men—companies that paid the highest wages in 1918 had unusually high labor turnovers. The largest turnover in the country was in a steel plant that paid high wages, in addition to giving large bonuses. The second largest turnover recorded was in a shipbuilding yard where record wages were in force.

It was also discovered that "speeding up" does not permanently help production nor hold men. The offers of large rewards resulted in spurts that were always short-lived. Reactions followed with a regularity that was convincing. The managements found that the steady worker is eventually the most valuable. The ideal conditions prevailed in shops where "pride in work" was considered more important than employment "methods." The best records of continuous individual production were in plants where employer and employee worked together, and where there was no suspicion on the part of the workmen that the owner was getting undue profits. It was in such plants that the labor turnover made a highly creditable showing.



If the war has taught nothing more than that money is not a universal cure-all for labor troubles, it has done some real good. Labor demands a recognized position, and corporations have got to give way to the yearning of their men for a place in industry equal in dignity to that of the employer. Wages may be used as an excuse, but the real fight of labor is a struggle to obtain a recognized position in society.

Let us no longer damn all unionism because a few of its representatives are demagogues. Every movement, no matter how laudable, is likely to occasionally get off the right track. What is required is patience and forbearance, with a complete understanding by capital that unions are results, not causes. We will have peace and plenty instead of boiling discontent when there is a healthy understanding between the parties to industry. The man must not be made to feel that he is the assistant to a machine. He must be permitted in some way to share in the fruits of good work. He must be made to feel that he can wear a white collar without being an object of curiosity to the balance of society.

IDEAS AND SUGGESTIONS

Device for Holding Cars Until They May Be Attached to the Cable

Considerable trouble was experienced at the mouth of a certain mine with the landing of trips and in attaching the trip to the plane rope, especially on snowy and rainy days. Before the little device here shown was devised sprags were used; and when the rails got wet

DEVICE FACILITATES THE HANDLING OF TRIPS

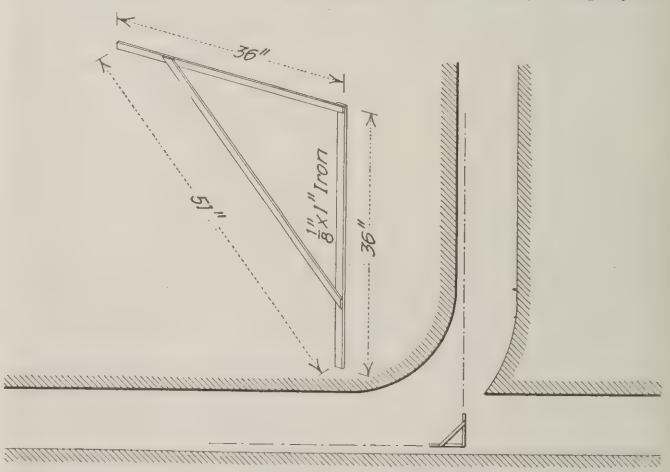
and the cars would slide, sand was necessary in order to prevent them going down the hill. To take out sprags on sand took up too much time. The device finally employed is shown in the accompanying illustration. The grade at the landing is 3 per cent. against the loads, 15 cars to the trip, 4 tons to the car. The cars are steel and weigh 3200 lb. each.

Fiber Rope Little Weakened by Frost

A recent note states that "Frozen Rope Causes Accidents" and that the rope is made brittle by freezing (*Coal Age,* Vol 15, p. 563), adding that the rope is weak. The following quotation from the *Engineering News-Record* justifies all these statements but qualifies the last as to the weakness of the rope.

"A recent test indicates that freezing does not, as has been generally believed, greatly lessen the breaking strength of fiber rope. Four specimens were cut from a 3-in. manila rope. All were spliced at both ends with an 8-in. splice. The length between the splices was 6 ft. Two specimens were soaked in water for 45 min., then exposed to an 18 deg. temperature from 5:30 p.m. to 9:30 a.m. Both were stiff with frost when tested. The other two specimens were kept unfrozen. The elongation, at 50 per cent. of the breaking load was 1¾ in., and at 80 per cent., 2 in. It was the same in all specimens. The breaking strains were, for the frozen rope, 10,000 lb. and 10,900 lb., and for the unfrozen rope 11,000 and 11,300 pounds."

This experiment was conducted by Fred A. Jenks, Plymouth Cordage Co., Plymouth, Mass., to answer an inquiry by the editor. Mr. Jenks comments as follows:



"The results were rather surprising. It was expected that the unfrozen rope would show comparatively a much larger breaking strain. As soon, however, as pull began to be exerted on the frozen rope the frost particles began to break up. After the rope had broken, the portion under stress was absolutely clear of frost, although in the splices, where the strain was on the double, the rope was still somewhat stiff from frost, and the ends of the tucks were completely frozen.

"Between pulling centers there was practically only a damp rope at the time of rupture. The pull had not only broken the frost crystals, but the heat generated by the friction in the strain and breaking of the rope had melted the frost. However, despite the showing made by the tests, everyone who has handled frozen rope knows that it cannot be as easily handled or run as freely over sheaves or used as well over capstans, and that it is much more difficult to secure. These facts alone constitute good reasons for protecting rope from the effects of frost."

Turning Off an Entry Without a Transit

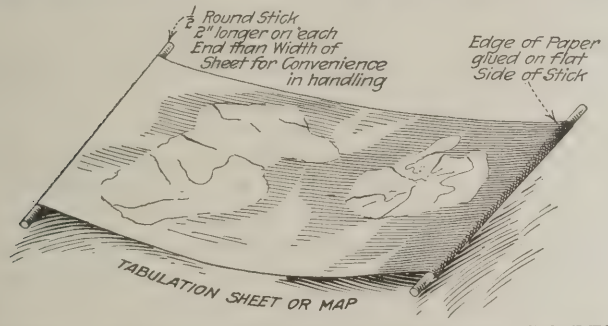
BY GAS INSPECTOR
Worley, Ky.

Many a mining man has been confronted with the problem of no engineer and no instrument, while half a dozen places needed turning off at once to avoid delay and other costly annoyances. The following description covers a method I have followed for many years, one that has proved successful and avoided the delay entailed by waiting for an engineer to arrive. It has proved to be so near correct that no expensive changes had to be made when the transit was finally employed.

METHOD OF USING SQUARE FOR TURNING ENTRIES

This method necessitates the use of a 36-in. square, readily made in the blacksmith shop out of ⅛ in x 1 in. iron, as shown in the diagram.

Sights are taken from the entry back plugs, and by the use of short strings and two plumb bobs the entry line is projected to a point opposite that where it is desired to start advancing, in the new passage. Here



place two knife-point dots on the roof or on a plank, and locate them not over 36 in. apart; then with a chalked string make a straight line from dot to dot; when one arm of the square is placed on this chalk mark a third dot mark at the side and near the end of the other arm gives a right angle. On the second and third dots, or marks, plugs and spads may be placed to direct the new place, be it room or entry.

If the new place is to be an entry, a change can be made in its turning so that it will form an easy curve at the entrance yet still retain the guide of the line established in the manner just described.

Wooden Edge Protector for Maps

By Roy H. Poston

Long maps, blueprints, and charts which require handling soon become frayed or torn unless the edges are protected. Frequently only one copy or set is available, and the destruction or obliteration of it would cause much inconvenience. One method of insuring proper

HOW TO PROTECT THE EDGES OF MAPS AND CHARTS

protection against such possibilities is to glue pieces of half-round wooden stick to the two opposite edges of the print, after the manner shown in the accompanying sketch. This permits the print to be rolled from either end, and thus avoids creases caused by folding, in addition to allowing greater convenience in showing any desired portion of the print.—*Engineering and Mining Journal.*

Why Not Avoid Traverse-Table Troubles?

By R. Dawson Hall

Associate Editor, *Coal Age*

Many traverse-table annoyances are due to the fact that the transit man does not have to traverse his own notes and feels no responsibility in consequence. He could save the officeman a lot of work if he would arrange, as far as possible, that the directions of all courses should lie an even number of degrees off the meridian and that the length of every course should be an even number of feet. Even where some bearings must, in the nature of things, be partly given in both degrees and minutes, and in feet, tenths and hundredths, there is no reason why all the courses should be so contrived. By simplifying the surveys we can save the length of the bearing notes to be entered on mine maps. Such bearings take up not only time in the office but space on the map. They often spoil the appearance and legibility of a mine plot.

The layout of the mine underground can often easily be made a little bit off the true butt and face. In fact the direction of the face is not readily determined. The engineer usually has some face heading running on a known bearing, and he parallels that in another heading when laying out a new mine. It would often be just as easy to make his butt headings run 60 deg. east of north and then half the traversing could be done by mental arithmetic. In any event there is no sense in standardizing on N59°/48′ E or some similar assumption, as likely to be erroneous as it is to be correct.

Much of the time in the office is wasted in trying to reconcile differences in the work of different transitmen or to discover why some one transitman does not arrive twice at the same result. Sometimes the whole series of bearings is corrected to make a survey "close," and new bearings are calculated. This cannot, of course, be entirely avoided, because the mensuration of distances by taping or stadia reading cannot be accurate.

There is no reason, however, why azimuths should not be accurately measured if the transitman will take the necessary care to set his instrument on a steady base, keep his transit in good adjustment, and read azimuthal bearings on the vernier. Mine-property surveys should tie to the minute and should usually close within two feet. They will not necessarily, of course, be correct to that degree as far as distances are concerned. All that a perfect tie shows is a uniformity of error in measurement throughout the length of the line surveyed.

It is a fact, not usually known, that the largest errors in surveying, outside of faulty records, arise not from erratic taping but from mistakes in the mensuration of angles, owing to the shifting of the transit between the fore and rear sights. An indifferent closure means a rerunning of the surveys with a new record of distances and bearings slightly different in azimuth and distance from the first. This makes the calculation in the office slow and burdensome and the record of the survey on the map, a bristle of figures.

Uses for Empty Carbide Cans

By E. P. Humphrey

Upper Lehigh, Penn.

Several uses can be made of the 100-lb. tin carbide containers, instead of throwing them away. They have a small refund value, but when the freight is paid it amounts to practically nothing. One use is to place them in the machine shop so that the machinists can put their turnings and borings into them, one for each kind; and then, when a car of scrap is to be loaded, the filled cans are placed in this car. The blacksmith also should have some for his scrap ends. This practice is not only a great labor saver for the mine or shop operator, but also for the receiver of the car, as it greatly facilitates unloading.

These cans may also find place in the shop, breaker or tipple as receivers for dirty cotton waste and wiping cloths. Some reclaim the cotton waste, and the oil residue is used on gearing. A few cans of this oily waste are handy in the winter time for thawing pipes. A locomotive fire may be easily started with it, saving good waste and oil which the engineer is likely to use in order to secure a quick, sure fire.

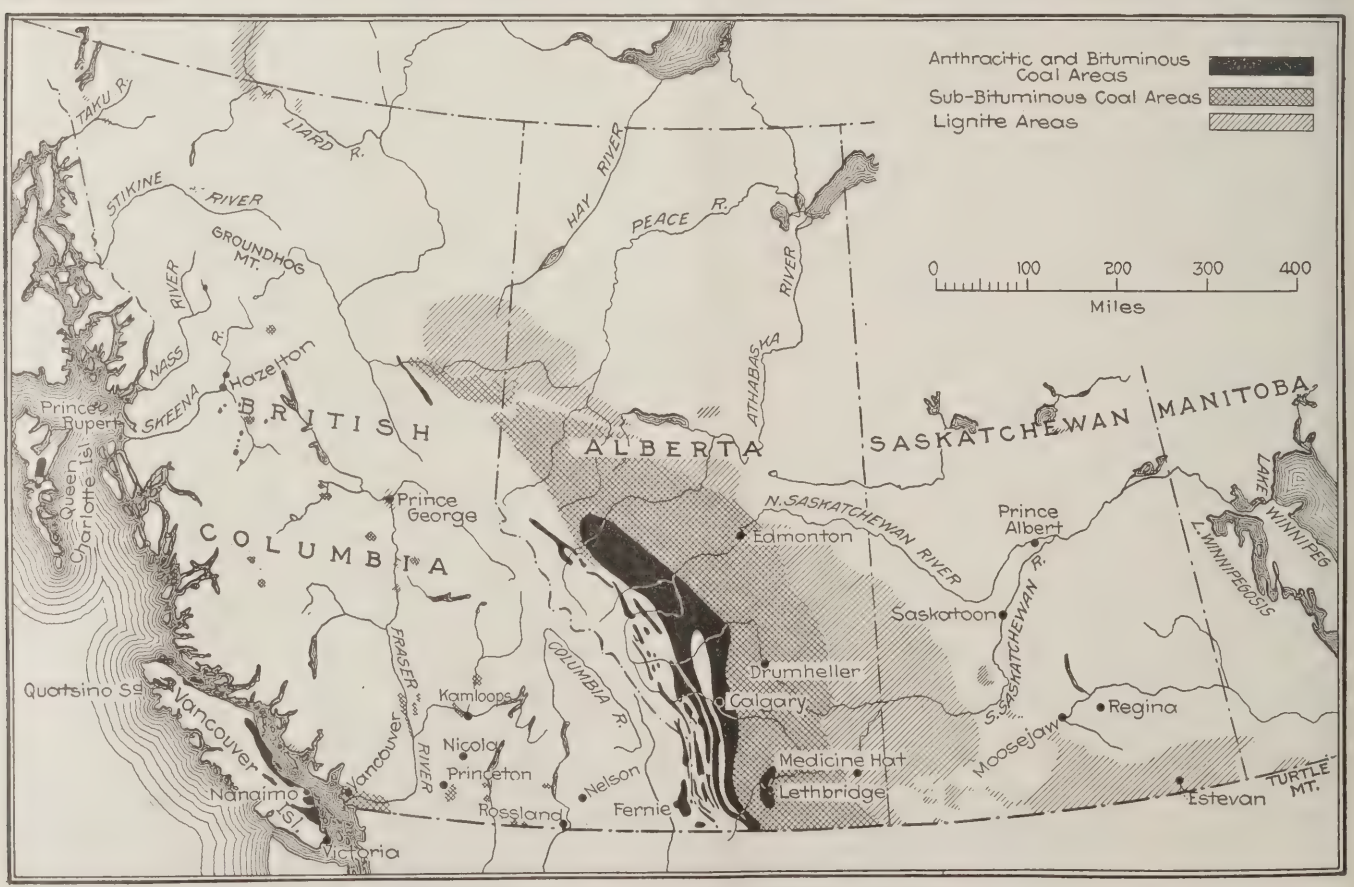
Another use lies in substituting the cans as bags for carrying feed to mules in the mines. They can be easily cleaned and dried, and with the screw top are moisture and rat proof. This feature is especially useful in the small mine, where there may be only one mule that is cared for by the driver. The tendency when bags are used as is the ordinary practice is for the feed to get wet and be left out for the rats.

Coal Resources of Western Canada—I

By James White
Assistant to Chairman, Deputy Head, Commission of Conservation, Ottawa, Canada

SYNOPSIS—*British Columbia, Alberta, Saskatchewan and Manitoba together have an actual coal reserve of 412 billion tons and in addition a probable reserve of 781 billion tons. Of the first, 669 million tons in actual reserve is semi-anthracite, the proportion of volatile matter in which is about 12 per cent. The lignites outrange all the other coals, there being 383 billion tons of lignite and sub-bituminous coals in actual reserve. Some of the lignites have nearly 24 per cent. of moisture, of which, however, air drying sometimes largely rids them.*

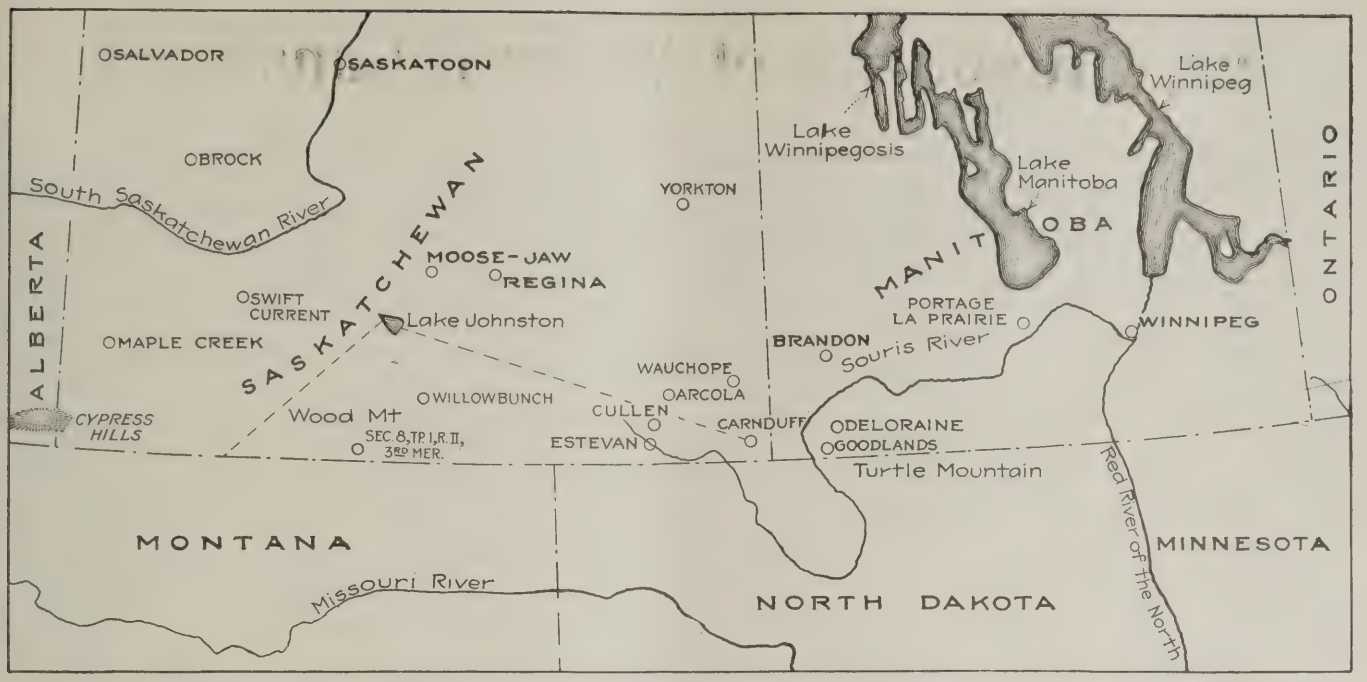
THE principal fuels of Western Canada[1] are coal, natural gas, petroleum, peat and wood. Electricity, to be generated by water power, will serve, also, as a substitute for fuel. Coal is, of course, much the most important fuel of Western Canada. It ranges in character from the lignite of the prairies to the semi-anthracite of the Rocky Mountains. Many of the following facts are taken from the "Coal Fields and Coal Resources of Canada," by Dr. D. B. Dowling, of the Geological Survey of Canada. Included in these is the statement as to the coal reserves of the provinces that are included in this area. The monograph quoted divides the reserves into two groups.



Group I includes all coal found in seams which contain not less than one foot of merchantable coal. However, when any seam occurs more than 4000 ft. below the surface it has been excluded from the calculation. The estimate also includes all the coal in workable submarine areas. This group, Dr. Dowling remarks, includes all the coal of economic value that is contained in seams of workable thickness situated within minable distance of the surface.

Group II includes the coal in seams which contain not less than two feet of merchantable coal wherever such seams occur at depths ranging between 4000 and 6000 ft. Such seams are situated beyond present minable distance of the surface and have not been considered in this paper.

Both groups are subdivided into actual and probable reserves. Actual reserves include coal the amount of which can be calculated with some degree of accuracy, being "based on a knowledge of the actual thickness and extent of the seams." Probable reserves include coal of which "an approximate estimate only" can be made.



At the present time, to be economically "workable"

[1]For the purposes of this paper Western Canada is taken as including Manitoba, Saskatchewan, Alberta and British Columbia, but not including Yukon or the Northwest Territories. The article is taken from a booklet issued by the Commission of Conservation entitled "Fuels of Western Canada." Everything not relating to coal is eliminated.

DISTRIBUTION OF COAL IN WESTERN CANADA

The areas shown as containing anthracite and bituminous coal include also, in places, sub-bituminous coal and lignite; similarly some of the sub-bituminous areas also contain lignite.

SOUTHERN SASKATCHEWAN AND MANITOBA, SHOWING POINTS MENTIONED IN ARTICLE

a seam must be more than one foot thick, and there is no coal mine in Canada that has a depth approaching 4000 ft., though, in the Crowsnest district, some workings have a "cover" several thousand feet thick. At great depth the greatly increased ventilation required is a matter of expense and difficulty; "creep" and subsidences of strata are unavoidable, and they either crush the coal or render it inaccessible. The capital required for the development of the mine and the current expenditure that its operation demands increases out of all proportion with depth, while the cost of raising water, coal, miners, etc., also advances.

Dr. Dowling's estimate of the coal reserves in Group I is as follows:

TABLE I. ACTUAL COAL RESERVES OF WESTERN CANADA IN MILLIONS OF METRIC TONS [1]

(Calculation based on actual thickness and extent)

	Lignite	Lignitic or Sub-bituminous	Low-Carbon Bituminous	Bituminous and High-Carbon Bituminous	Semi-Anthracite	Total
Saskatchewan	2,412	.....	.....	.....	...	2,412
Alberta	.....	382,500	1,197	2,027	669	386,373[3]
British Columbia	.....	60	118	23,653[2]	...	23,831
Total	2,412	382,560	1,315	25,680	669	412,616[3]

PROBABLE COAL RESERVES OF WESTERN CANADA IN MILLIONS OF METRIC TONS

(Approximate estimate)

	Lignite	Lignitic or Sub-bituminous	Low Carbon Bituminous	Bituminous and High-Carbon Bituminous	Semi-Anthracite	Total
Manitoba	160	.....	.....	.....	...	160
Saskatchewan	57,400	.....	.....	.....	...	57,400
Alberta	26,450	464,821	139,161	43,022[2]	100	673,554
British Columbia	.....	5,136	2,300	42,608[4]	...	50,044
Total	84,010	469,957	141,461	85,630	100	781,158.

[1] Metric ton is equivalent to 2,204.62 lb., practically a long ton. No conversion has been attempted because the figures are not, of course, so absolutely accurate that this course is advisable.
[2] Includes semi-anthracite.
[3] Total after deducting 20 million tons mined in 1911.
[4] Includes 1,800 million tons of cannel.

TOTAL COAL IN WESTERN CANADA (GROUP I)

	Tons	Per Cent.
Manitoba	160,000,000	0.1
Saskatchewan	59,812,000,000	6.1
Alberta	1,059,927,400,000	88.8
British Columbia	73,874,942,000	5.0
Total	1,193,774,342,000	

The classification of coals adopted in this paper is that used in the "Coal Resources of the World," as below:

Anthracite—Fuel ratio,[2] 12 or over; Calorific value, 14,500 to 15,000 B.t.u.; Carbon, 93 to 95 per cent.; Volatile combustible matter, 3 to 5 per cent.

Semi-anthracite—Fuel ratio, 7 to 12; Calorific value, 15,000 to 15,500 B.t.u.; Carbon, 90 to 93 per cent.; Volatile combustible matter, 7 to 12 per cent.

Anthracite and High-carbon Bituminous—Fuel, ratio, 4 to 7; Calorific value, 15,200 to 16,000 B.t.u.; Carbon, 80 to 90 per cent.; Volatile combustible matter, 12 to 15 per cent.; does not readily coke.

Bituminous—Fuel ratio, 1.2 to 7; Calorific value, 14,000 to 16,000 B.t.u.; Carbon, 75 to 90 per cent.; Volatile combustible matter, 12 to 26 per cent.; generally cokes.

Low-carbon Bituminous—Moisture content occasionally reaches 6 per cent.; Volatile matter, up to 35 per cent.; $\frac{\text{Fixed carbon} + \frac{1}{2}\text{ volatile}}{\text{Hygroscopic moisture} + \frac{1}{2}\text{ volatile}} = 2.5$ to 3.3; Calorific value, 12,000 to 14,000 B.t.u.; Carbon, 70 to 80 per cent.; makes porous, tender coke.

Cannel—Yields 30 to 40 per cent. volatile matter on distillation; Calorific value, 12,000 to 16,000 B.t.u.; very porous coke.

Lignite or Sub-bituminous—Generally contains over 6 per cent. of moisture; Moisture, freshly mined, up to 20 per cent.; $\frac{\text{Fixed carbon} + \frac{1}{2}\text{ volatile}}{\text{Hygroscopic moisture} + \frac{1}{2}\text{ volatile}} = 1.8$ to 2.5; Calorific value, 10,000 to 13,000 B.t.u.; Carbon, 60 to 75 per cent.

[2] The fuel ratio is obtained by dividing the percentage of fixed carbon by the percentage of volatile matter.

Lignite—Moisture in commercial output, over 20 per cent.; Calorific value, 7000 to 11,000 B.t.u.; Carbon, 45 to 65 per cent.

MANITOBA

In Manitoba, the Turtle Mountain coal field occupies an area of about 48 square miles. About 1890, an attempt to mine coal was made near Goodlands, but it was unsuccessful, probably because the seams were thin and of poor quality. Coal has also been mined near Deloraine, but only for local use. The insignificance of the production is indicated by the fact that the "Annual Report on the Mineral Production of Canada," published by the Mines Branch, Ottawa, gives no statistics of coal production in Manitoba. The "probable," not "actual," reserves are estimated at 160,000,000 tons of lignite.

Dr. D. B. Dowling states that "the coal horizon does not appear to consist of a series of seams in continuous sheets, but rather of deposits which are limited in extent though repeated over large areas. A thick seam may thus be represented in an adjoining locality by a series of thin seams separated by sheets of sand or clay."

SASKATCHEWAN

In Saskatchewan, two coal-bearing formations are exposed, namely, (1) the Belly formation of the Cretaceous and (2) Tertiary, which is much more important than the Cretaceous, and underlies the Estevan District, Wood Mountain and the Missouri Coteau.[3] The two principal fields are roughly triangular in shape. The latter is bounded on the northeast by a line extending from the vicinity of Carnduff to Johnston lake, on the west by a line thence to the international boundary west of Wood Mountain and on the south by the international boundary. The other field extends from the boundary between Saskatchewan and Alberta to the vicinity of Swift Current and includes the eastern portion of the Cypress Hills.

"Pearce" indicates that the data were obtained from a blue print compiled by William Pearce, Calgary, and are "from various sources believed by the compiler to be reliable."
‡Coal dust briquetted with about 10 per cent. coal tar.

[3] Coteau, a hilly upland adjacent to a river or between two rivers. —Editor.

The Souris Valley is about 120 ft. deep near Estevan and presents peculiarly advantageous conditions for prospecting and for mining the seams that outcrop in its banks and in the tributary gullies and ravines. Though there can be little doubt that enormous areas in Saskatchewan are underlaid by coal seams, the heavy covering of boulder clay conceals their outcrops and, except in occasional rock exposures in the hillsides and stream valleys, their existence can only be determined by boring. At the Estevan mines, most of the coal is produced from the lower measures, the thickness of the mineral at this point being 8 ft. In the western portion of the district, the bed splits up into several small seams; but it is reported that to the northeast it increases to 15 feet.

Lignite has also been reported near Cullen, 16 ft.; Arcola, 14 ft.; Wauchope, 8 ft.; and in a number of localities, particularly in the Wood Mountain and Cypress Hills districts. Coal has been found in borings or natural exposures of rocks of the Belly River formation in the western portion of Saskatchewan, notably at Maple Creek, Brock and Salvador. It carries from 27 to 34 per cent. fixed carbon. Coal carrying 35 per cent. fixed carbon has also been found in the Dakota sandstone (Cretaceous) near lac la Ronge.

It is estimated that, in Saskatchewan, an area of 13,100 square miles is underlaid by coal seams. The "actual" and "probable" reserves of coal aggregate 59,812 million tons, all lignite. The annual production of coal in Saskatchewan during the period 1898-1917 is shown in Table IV.

The output of the mines in the Souris field constitutes 95½ per cent. of the production of the province. The mines at Gladmar and Hart produce about 1½ per cent., the remainder of the output coming from mines that produce less than 1000 tons each per annum.

Alberta

As indicated in Table I the "actual" and "probable" reserves of coal in Alberta are estimated as aggregating 1,059,927 million tons, and constitute 87 per cent. of the coal in Canada. The coal horizons in Alberta are: (1) Edmonton formation, with which may be associated the Paskapoo beds. (2) Belly River formation. (3) Kootenay formation. Coal is found in the Tertiary rocks, but most of the seams are too thin to mine.

Of the total area, 24,779 square miles, occupied by the Edmonton and Paskapoo beds, 22,475 square miles is assumed to be underlaid by coal. The "actual" and "probable" reserves in these beds aggregate 789,600 million tons of lignitic or sub-bituminous coal and 11,358 million tons of low-carbon bituminous. Of the reserves in the Edmonton formation, 98.6 per cent. is lignite or sub-bituminous and 1.4 per cent. is low-carbon bituminous.

TABLE IV. ANNUAL COAL PRODUCTION IN SASKATCHEWAN, 1898–1917

	Tons	Value		Tons	Value
1898	25,000	$37,500	1908	150,556	$253,790
1899	25,000	37,500	1909	192,125	296,339
1900	40,500	60,750	1910	181,156	293,923
1901	45,000	72,000	1911	206,779	347,248
1902	70,400	112,640	1912	225,342	368,135
1903	116,703	169,618	1913	212,897	358,192
1904	124,885	187,021	1914	232,299	374,245
1905	107,596	152,334	1915	240,107	365,246
1906	108,398	164,146	1916	281,300	441,836
1907	151,232	252,437	1917	355,445	662,451

TABLE V. COAL PRODUCTION OF ALBERTA IN THE PERIOD 1898–1917*

	Tons	Value		Tons	Value
1898	315,088	$787,720	1908	1,685,661	$4,127,311
1899	309,600	774,000	1909	1,994,741	4,838,109
1900	311,450	778,625	1910	2,894,469	7,065,736
1901	340,275	850,687	1911	1,511,036	3,979,264
1902	402,819	960,601	1912	3,240,577	8,113,525
1903	495,893	1,117,541	1913	4,014,755	10,418,941
1904	661,732	1,404,524	1914	3,683,015	9,350,392
1905	931,917	1,993,915	1915	3,360,818	8,283,079
1906	1,246,360	2,614,762	1916	4,559,054	11,386,577
1907	1,591,579	3,836,286	1917	4,736,368	14,155,685

* "The Production of Coal and Coke in Canada, During the Calendar Year 1916," p. 29. By John McLeish, Mines Branch, Department of Mines, Ottawa.

The Edmonton formation forms a wide trough lying approximately parallel to the Rockies and extending from the international boundary to about latitude 55° 30′. The central portion of the trough is occupied by Tertiary sandstones.

The "Big" coal seam, which is 25 ft. thick where

ALBERTA, WITH LEADING COAL CENTERS

it outcrops on the North Saskatchewan, consists of two 10-ft. seams near the Grand Trunk Pacific crossing of the Pembina River. It is 10 ft. thick on the Red Deer River near Alix, but decreases to about 5 ft. south of the Bow River.

Another persistent coal horizon is found 500 to 600 ft. below the "Big" seam. At Calgary, where it has been found in a borehole 1800 ft. below the surface, it is 13 ft. thick; near Drumheller it is 6 ft. 10 in. thick; on Battle River it has a thickness of 4 ft. At Edmonton, there are two seams of good domestic coal, each about 6 ft. thick.

The Belly River formation occupies a considerable area in the southeastern portion of the province. The most important seams in this formation are exposed at Lethbridge. At this point, the main seam is 5 ft.

6 in. thick. The probable reserves in the Belly River are: Lignite, 29 per cent.; lignitic or sub-bituminous, 10.5 per cent.; low-carbon bituminous, 60.5 per cent.

The discovery of a 4-ft. and a 7-ft. seam at Maple Creek, at depths of 197 and 292 ft. respectively, indicates that this formation contains workable seams as far east as southern Saskatchewan.

What is assumed to be the "upper" seam has been found at Tofield, at a depth of 1050 ft., and at Edmonton, at a depth of 1400 ft., where it is 6 ft. thick. At Calgary, a 5-ft. seam found at 2562 ft., a 7-ft. seam at 2656 ft. and a 4-ft. seam at 2875 ft. are believed to be in the Belly River formation.

The Kootenay formation is exposed in and near the Rocky Mountains. As a result of the great uplift of the Rockies, the upper measures were denuded and only remnants of the lowest division of the Cretaceous—the Kootenay—survived. These remnants are usually found occupying valleys between the mountain ranges, the mountains having served as a protecting agency. At the same time, the crumpling and folding of the strata during the uplift of the mountains have given us a coal that, in places, is semi-anthracite or is anthracitic. It is estimated that, of the "actual" and "probable" reserves, 1.7 per cent. is semi-anthracite and 98.3 per cent. is high-carbon bituminous or bituminous. The coal in the Kootenay formation is the highest grade found in the Prairie Provinces.

TABLE VI. PRODUCTION OF COAL IN ALBERTA, 1917, BY DISTRICTS

District	Production, Short Tons	Per Cent. of Total
Anthracite:		
Banff	108,225	2.3
Bituminous:		
Crowsnest Pass	1,188,456	25.1
Canmore	196,947	4.2
Brazeau	266,823	5.6
Jasper Park	248,733	5.2
Yellowhead Pass	159,182	3.4
Mountain Park	139,164	2.9
Total bituminous	2,199,305	46.4
Lignite:		
Pincher Creek	4,652	0.1
Lethbridge	614,017	13.0
Magrath	936	...
Milk River	8,047	0.2
Taber	157,373	3.3
Bow Island	6,043	0.1
Medicine Hat	13,975	0.3
Aldersyde	7,076	0.2
High River	1,126	...
Drumheller	631,767	13.3
Big Valley	26,753	0.6
Brooks	9,233	0.2
Hanna	25,670	0.5
Lacombe	16,097	0.3
Trochu	15,023	0.3
Three Hills	22,457	0.5
Carbon	4,301	0.1
Battle River	9,862	0.2
Camrose	56,625	1.2
Tofield	68,806	1.5
Clover Bar	256,208	5.4
Edmonton	121,080	2.6
Namao	18,195	0.4
Cardiff	237,861	5.0
Wabamun	13,534	0.3
Pembina	81,911	1.7
Peace River	210	...
Total lignite	2,428,838	51.3
Total production	4,736,368	....

In Alberta, the three principal seams in the Coleman area have a thickness of 16 ft., 10 ft., and 8 ft. respectively. In the Blairmore area there are seams 10, 17, 3½, 3½, 17 and 6 ft. thick respectively. A seam 20 ft. thick has been reported in the Moose Mountain area. In the Banff area, the coal varies from anthracite to bituminous. In the southeastern portion of the field there is a total thickness of coal of from 41 to 86 ft. At Bankhead, the workings have cut seams 3 ft., 7 ft. (in thin bands), 8 ft., 19 ft. (in two benches), 13 ft. (in three benches) and 6 ft. thick respectively.

In the Bighorn basin, seams aggregating about 60 ft. of workable coal have been found. Seams of 21 ft., 7½ ft. and 4½ ft. are being mined at Mountain Park. Coal is also found in the Kootenay formation at numerous other points in the Rockies and in the foothills. On the Muskeg River, seams 11½ ft., 25 ft. and 7 ft. thick respectively, have been found.

The Chief Inspector of Coal Mines for Alberta states that in 1916 the total sales in Canada of coal produced in Alberta were 4,227,164 tons; that 2,956,205 tons were sold for consumption in Alberta, 1,021,656 tons in Saskatchewan, 98,629 tons in Manitoba, 89,582 tons in British Columbia and 61,092 in the United States.

The total coal production of Alberta, in 1917, was 4,736,368 tons. Of this production, 2,428,838 tons, or 51.3 per cent., was lignite; 2,199,305 tons, or 46.4 per cent., was bituminous; 108,225 tons, or 2.3 per cent., was semi-anthracite.

(To be concluded)

Coal and Oil in Rhode Island

By Kirby Thomas
New York City

A full-fledged oil drilling rig, installed on Connanicutt Island, Narragansett Bay, Rhode Island, is a sight that might well surprise the oil expert and the engineer, yet the fact exists and the conditions of its being are interesting. The American Oil Co., of Boston, successor to several companies formed in recent years to fathom the geological mysteries of the smallest state in the union, erected in 1918 a rig on the eastern shore of the island and drilled to a depth of 2000 ft. for oil. In the previous year, a subsidiary interest, using a Star rig, drilled to 1300 ft., in the same locality.

In both cases the results were negative as to oil, although some interesting data as to the extent and character of the graphitic shale of the area were brought to light. The geological formation drilled is a southerly extension of the coal-bearing horizon in which to the north, at Portsmouth, several years ago the Whitney interests of Boston undertook an ambitious, but ill-fated, operation in coal.

On Connanicutt Island the graphitic shales appear to correspond to the coal measures at Portsmouth; and the drilling, while disclosing no coal measures, confirmed this relation in a general way. The drills were sunk to the underlying basal sandstone and probably through the geological measures which correspond to those in which the Portsmouth coal is found. The strata on the island dip to the west about 45 deg. and appear to be duplicated by a fold or fault between the east and west shores.

This local structure furnished the assumption for a syncline on which the oil experts based their hopes. The strata were all found to be highly metamorphosed.

This oil exploration has had the result of settling the question of whether or not the Portsmouth coal measures would be found in that direction. It is only a few years ago that a company was formed to develop coal on the island on this same property. The American Oil Co. is now planning to develop and operate the graphite deposits and has apparently given up expectations of finding oil.

The New Pittsburgh Station of the Bureau of Mines—II

By George W. Harris
Editorial Staff, "Coal Age"

OPPORTUNITY for research is offered to an unusual degree in all phases of mining and allied fields in this comparatively new bureau, which has attracted many enthusiastic experts and specialists. Their services are directed largely to the working out of special technical problems. While the war lasted the work of the Pittsburgh station was entirely devoted to the demands that were made upon it for assistance on problems connected with war work, but plans are now completed for a return to a peace basis. The organization is being strengthened by a larger personnel, including many of those formerly connected with the Pittsburgh station.

In reviewing the work of the Bureau of Mines during the past two years especial attention should be called to Director Van H. Manning, who on account of rare vision was quite prepared to assist in war work. He saw that sooner or later we would get into the war, and also how it would be possible to merge into war activities—especially gas work. When the time came, the Bureau simply took it up without asking for the assistance of anyone. The slogan was—Is this going to help win the war? If that test could not be met satisfactorily, then the force was put on something that would be of assistance in winning.

G. A. Burrell was placed in charge of war gas investigation; until the war broke out he had charge of gas investigations in the Bureau's laboratory, and was a leading expert in gas work. Various men of the Bureau assisted Mr. Burrell, among whom were A. C. Fieldner, supervising chemist, on testing absorbents for gas masks and the masks themselves; J. W. Paul, chief coal mining engineer (in the early part of the work), on design and tests of gas masks and training of army officers in the use of masks; D. J. Parker, mine safety engineer, in charge of mine rescue work; W. E. Gibbs, the inventor of the Gibbs rescue apparatus, on mechanical design; H. H. Clark, electrical engineer, with his assistants, devoted his time to gas masks and other appliances used in warfare. On the physiological side, Yandell Henderson, a consulting physiologist of the Bureau and the Yale School of Medicine, was called in to organize in his specialty; he was associated with D. J. Parker on matters pertaining to breathing apparatus.

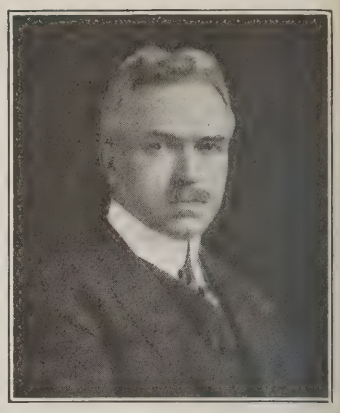
VAN H. MANNING
Director of Bureau of Mines

All the chemical work in connection with the designing and making of the first lot of gas masks, in the early part of the war, was done in Pittsburgh, as was also the testing. The whole problem grew so that the undertaking had to be established in a separate station. Accordingly the American University site in Washington was used, and new buildings were put up in which to carry on the work. The Bureau force was moved down there in September, 1917, and was added to from other sources; when taken over by the War Department in July, 1918, some 1500 men were included and incorporated in the Research Division of Chemical Warfare Service. On the facing page is shown the latest type United States Army Tissot mask, which is pronounced superior to the mouthpiece type largely used in the war and copied from the English model. The United States Army mask is more comfortable to wear, has a larger angle of vision and men are able to fight better with it on than with that of any other make.

D. A. LYON
Supervisor of Stations

Considerable prominence might to advantage be given to the gas mask illustrated, as it is one of the types which will be used in the industries. Furthermore, the Bureau of Mines not only took an active part in its development but expects to follow up the matter in connection with its future usefulness. Therefore a brief description of the mask would be fitting. It consists essentially of a facepiece of rubber backed up with fabric; it carries two eyepieces and a connection for a flexible rubber tubing to a canister of absorbents. The canister is supported in a knapsack slung from the neck. This canister contains a mixture of 60 per cent. charcoal and 40 per cent. soda lime, by volume; there is an inlet valve in the bottom and an exhalation valve on a small metal casting attached to the facepiece. The wearer of this mask breathes through the canister, which filters out poison gases and gives him pure air. This mask is limited as to efficiency to 1 per cent. and less of concentrations of gases; in the case of higher percentages, some of the gases pass through the absorbents. Also, the standard filling in the canister being an alkali is intended to neutralize the acid which is the base of many of the poison gases used in the war. This mask will not replace the rescue breathing apparatus used in mines, around blast furnaces, gas producers or illuminating gas plants. It should not be used in places where oxygen is scarce.

A. C. Fieldner, the authority for the gas mask information, also states that the Bureau of Mines is interested in the problem of a suitable absorbent for carbon monoxide and expects, in the not far distant future, that a suitable canister filling for carbon monoxide will become available. It has its legitimate field, but great caution is necessary in its use. In general no mask should be used in gas unless an expert has first looked into the matter. The Bureau of Mines



expects to advise in such cases when requested and will approve any mask submitted by manufacturers which will do the work claimed for it. This is similar to the investigations and tests which are now conducted in the case of explosives, lamps and motors. Permissible masks should meet with popular approval.

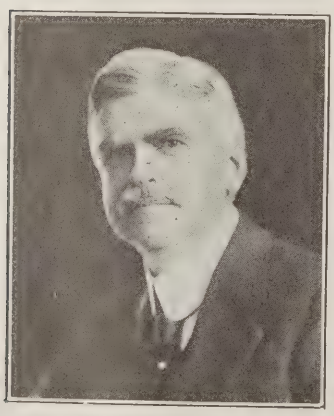
The explosives laboratory at the Pittsburgh station did a great deal of research work on new military explosives—also on the substitution of other materials which could be used in the manufacture of industrial explosives to satisfy heavy demands. Of course, much of this work done on military explosives will apply to mining; and this same principle will hold true as regards gas mask work also.

The public does not tire of hearing about the war history of our institutions and industrial plants. This should be especially true in regard to the activities of the Bureau of Mines during this trying period. Among the stations of the Bureau the one at Urbana, Ill., was chiefly occupied in the problem of recovery of sulphur from coal brasses (iron pyrites) for use in the manufacture of sulphuric acid. Coal operators would certainly welcome a permanent and satisfactory solution of the problem of the utilization of sulphur found in coal beds. Also here was solved the problem of the utilization of the coals of the middle west for gas manufacture; formerly it was considered that eastern coals were essential for this purpose.

In the State of Washington, fuel oils were shut off as the war absorbed this product, and accordingly a study was made of this situation to show how to utilize the coals of that immediate section to take the place of oil fuel.

It is of interest to know just how each of these stations functions and fits in with the general plan of the Bureau of Mines—each attempts to serve the district in which it is located. The Pittsburgh station is the most important one of the Bureau by reason of its size and the appropriation made for it. By reason of its facilities and staff it can serve the other stations in various ways, such as reference, computing, photographic and analytical work; the smaller stations can undertake much of this work only in a limited way on account of their smaller appropriations. Furthermore, there is a limited demand for such work at any one of the other stations. An endeavor is made to coördinate the work of all so as to prevent any useless duplication and to insure the use of plant and equipment to the fullest extent. In commenting on the field of labor of the Bureau of Mines, emphasis has been placed more or less on the research work of this institution. However, D. A. Lyon, the supervisor of stations, states that the Bureau of Mines is not merely a big research body—that it does the work within its scope. This action is definitely established by an act of Congress—either the prevention of loss of life or the saving of waste. In discussing this point with Mr. Lyon, he stated that if there is any doubt as to the propriety of going ahead in any matter, it is generally easy, if the broad act establishing the Bureau is considered, to determine whether or not a given problem falls within the scope of the work as planned when the Bureau was authorized.

O. P. HOOD
Chief Mechanical Engineer of the Bureau



HOW TISSOT MASK IS ADJUSTED

As the Bureau developed it was evident that a field station should be planned so as to be able to coöperate with the commercial establishments and institutions around it. Thus at the Pittsburgh station the idea would be to build up research in coal mining in all its ramifications; those matters naturally claiming attention here would be safety or accident prevention, mining methods, the minimizing of waste, permissible explosives and ventilation problems, among others. But possibly the biggest problem of all is the utilization of coal. Naturally the mining companies encourage the buying of coal—it is the consumer who has in mind its saving; the whole nation is interested in saving fuel and in its most efficient utilization in every industry. But after all the major premise is the life and health of the miner and the prevention of the waste of resources.

The Pittsburgh station is a big institution devoting much of its energy to matters connected with coal and coal mining. It is right and proper that it should do so, as 50 per cent. of our investments are in connection with fuel. The next single item as to investment is iron, representing 24 per cent.; all other metals are a little more than 25 per cent. The Bureau has tried to proportion the work of the stations to the money invested and to meet the needs of all the industries. In a coal sense many of the fuel problems of Pittsburgh are those of the coal fields of the whole country.

Environment has great weight. Dr. Holmes' original idea was to have one big station in the East and another in the West, and other stations distributed over the country, as an act of Congress provides. It is most desirable to have a Bureau station rub elbows with an industry in each particular instance. In the event

GEORGE S. RICE
Chief Mining Engineer of the Bureau

of a laboratory far removed from a practice to be investigated, it would be one thing to read about it and quite another matter to sense the problem by actual contact with the industry. It might be said here that it is not only to save fuel that the Bureau attacks the problems of an industry, but also to discover means of cheapening a process as well.

Professional ethics are strictly observed by the Bureau in its relations with consulting engineers and chemists. This matter is one it has to contend with, and the Bureau observes the rule of not encroaching on the field of the engineer in private practice in a competitive sense. This idea is kept uppermost even if it results in no action being taken toward the solution of problems which distinctly fall within the scope of the Bureau's work. Also if the problem is of a purely limited and local nature, possibly concerning a single individual, then this party is advised to have the matter attended to by his own engineer. But if a problem is one that has not been solved, and it is of a sufficiently broad scope, then the Bureau is glad to undertake its solution.

The new Pittsburgh station of the Bureau of Mines was to be essentially a laboratory for the investigation of coal and iron problems and the practical application of its findings to these industries. Nevertheless, it also was to be in the nature of a clearing house for the other stations throughout the country. It seems to be developing along these broad lines.

(*To be continued*)

Coal and Coke Operations of the United States Steel Corporation

The United States Steel Corporation mined 25,393,155 tons of coal for use in the manufacture of coke, and 6,354,980 tons for steam, gas and all other purposes in 1918, a total of 31,748,135 tons of coal. The annual report for this company for the fiscal year ended Dec. 31, 1918 was made public on Mar. 31. This report also shows that during last year 9,962,403 tons of coke were manufactured in beehive ovens and 7,795,233 tons in the byproduct type, a total of 17,757,636 tons as compared with 17,461,675 tons the previous year.

The total amount expended by the corporation and its subsidiary companies during the year 1918 for safety work was $1,110,064; $998,800 was spent in a similar way in 1917. Compared with results in 1917, the fatal and other serious accidents per 1000 employees showed a decrease of 7.64 per cent.; compared with 1906 there was a decrease of 46.1 per cent. The total amount disbursed by all the corporation companies during 1918 in connection with work accidents was $3,336,459. Of this sum 87 per cent. was paid directly to the injured employees or their families, or in taking care of them. These payments were made either under the corporation's voluntary accident relief plan or under the provisions of the Workmen's Compensation Laws of the several states in which the subsidiary companies are operating.

During 1918 the Steel Corporation acquired the following territory: In Pennsylvania, 117 acres of coking coal and 37 acres of surface were purchased in the Connellsville district; in the Pittsburgh district (Greene County), 14,207 acres of steam coal were bought; in Vermillion county, Illinois, 584 acres of coal land were acquired; 200 acres of coal and 104 acres of surface were purchased in the Black Mountain district of Kentucky. Additional mining and shipping equipment was provided for the Palmer, Dilworth, Maxwell, Gates, Leckrone, Ralph and Ronco mines in the Connellsville district. In the Pocahantas field, West Virginia, 130 tenements were completed, also 169 other houses and a clubhouse; street and sanitary improvements were made at various works.

The number of employees on the coal and coke properties of the corporation during 1918 was 28,378, as compared with 26,189 in 1917. The average salary or wage per employee per day, including general administrative and selling force, was $5.38 in 1918; it was $4.16 in 1917. Employees, to the number of 34,407, or about one-eighth of the total average number of employees in all departments of the corporation, entered the active military and naval service of the United States during the war.

In what is known as the northern coal and coke property, the corporation has 219,205 acres of coking coal, 115,362 acres of steam coal and 80,059 acres of surface. Here there are 71 coke plants, eight of which are equipped with apparatus for the recovery and rectification of benzol; 21,796 beehive and 2558 byproduct ovens are included in this district.

In the corporation's southern coal and coke property there are 190,696 acres of mineral and surface lands; this includes 139,329 acres of mineral only and 13,823 acres of surface only. There are located on developed sections of this property nine coal-mining plants comprising twenty operating mines, producing coal both for shipment and for manufacture into coke. In connection with these coal-mining operations there are ten coal-washing plants and seven coking plants, the latter comprising a total of 2974 beehive coke ovens. At Fairfield, Ala., there is located a byproduct coke works consisting of 280 ovens, with 154 additional ovens under construction to be ready in part by July, 1919. A benzol recovery plant is connected with this byproduct plant.

In the Pennsylvania Connellsville coke region the corporation's subsidiary companies own water-supply plants, consisting of 13 reservoirs and six pumping stations with a distributing system of pipe lines aggregating about 92 miles in length. These plants have a daily capacity of 18,000,000 gal., furnishing water for use in manufacturing coke and, in addition, supplying water to three municipalities.

Nitrogen Decreases with Carbonization

Nitrogen in coal is of uncertain occurrence. In the analyses contained in Bulletin 22 of the Bureau of Mines, the highest content of nitrogen in what is commonly, even though erroneously, called pure coal substance (casting out certain obvious errors in tabulation) is 2.65 per cent. The coal containing this percentage comes from Carbonado, Pierce County, Washington. It is a bituminous coal having 29 per cent. of volatile matter and about 5 per cent. of moisture. The same ash- moisture- and sulphur-free analysis of an extremely anthracitic coal at Portsmouth, R. I., ran only 0.12 per cent. In general the more complete the carbonization the smaller the nitrogen content, but there are several exceptions to this extremely rough rule. It is probably true of any one type of coal that the nitrogen content of so-called pure coal substance decreases with carbonization.

Research and Progress in Byproduct Coking in Great Britain—IV*

By John B. C. Kershaw
Colwyn Bay, Wales

SYNOPSIS—*Coals are usually crushed and mixed before coking, as certain advantages are secured thereby. The proper proportion in which coals of varying quality should be blended has been heretofore the subject of experiment, but it would appear that these data might now be determined in the laboratory. A new byproduct coking plant is briefly described. The moisture content of coal as charged to the oven exerts a potent influence on the amount and quality of byproducts obtained. This influence is particularly strong on the quantity of ammonium sulphate secured.*

THE economic and other advantages of using mixtures of coking and non-coking coals in byproduct ovens have long been recognized in America, and all up-to-date coking plants in the United States are now equipped with coal-crushing and mixing machinery, in order that the various kinds of coal it is desired to employ may be crushed to uniform size and mixed in the proper proportions. This method of improving the yield of coke is also now in use to a considerable extent in England, especially in those districts where non-coking coals high in nitrogen content are mined. In these cases the increased yield of ammonium sulphate obtained more than covers the cost of the crushing, grading and mixing of the coking and non-coking coals.

The method of selecting the coals that will give the best results and deciding what proportion to use in the mixture has been developed along purely empirical lines both in England and America. It is therefore of distinct interest and gain to the byproduct coke industry to find two French chemists, Charpy and Godchot, asserting in a recent contribution to *Comptes Rendus* that it is quite possible by laboratory trials to determine what coals are the best for the purpose, and in what proportions they should be mixed in order to give the hardest coke, under practical conditions.

These two authors, in an earlier contribution to the same journal, described a laboratory method of examining the physical and chemical properties of coke and showed that different varieties of coal, when coked, require different thermal treatment in order to obtain the best results.

In the more recent investigation they have applied the same methods of laboratory examination to mixtures of lean and rich coals, in order to determine whether in this case, also, laboratory methods can be employed to determine the best proportions for coking purposes. Using a temperature of 700 deg. C. (1292 deg. F.) (which was found by preliminary trials to give the best carbonization), and different proportions of "de Brassac" and Durham coals, the results given in Table I were obtained.

The rapid variation in the figures for the resistance of the coke given in the table shows how important it is to make a preliminary study of the best thermal conditions and proper proportions when carbonizing mixed coals. The percentage of "volatile matter" in the two coals used or in the mixture when made (which is sometimes relied upon) is no guide to the quality or hardness of the coke produced.

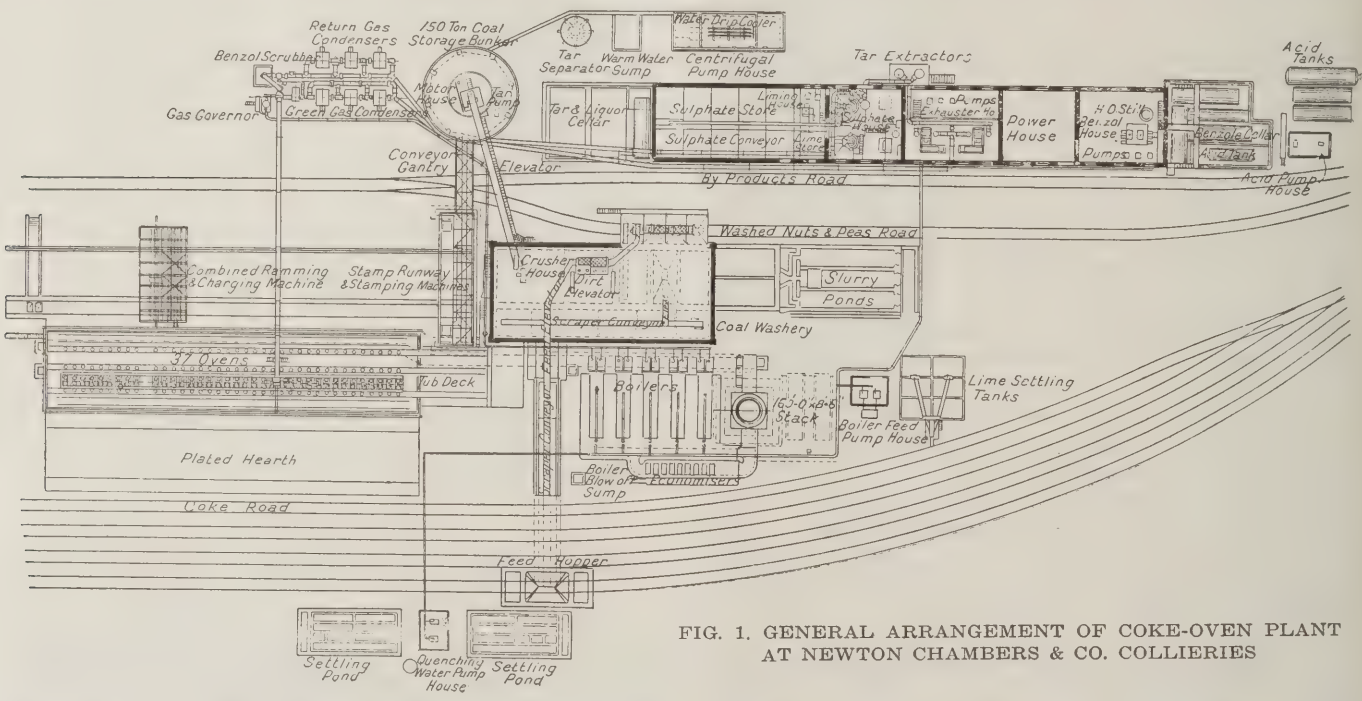


FIG. 1. GENERAL ARRANGEMENT OF COKE-OVEN PLANT AT NEWTON CHAMBERS & CO. COLLIERIES

*The third article of this series was published in *Coal Age*, Nov. 21, 1918.

As an example of this, the best hardness test obtained in the series quoted above corresponded to an average volatile test of 19.60 per cent. Another mixture of Durham and Cardiff coal, however, has given a maximum hardness test for the coke of 1000 lb. per sq.in. with proportions representing only 16 per cent. of volatile matter in the mixture; and when this content was raised to 19 per cent. the coke lost all cohesive properties, and its resistance to crushing fell to zero.

Charpy and Godchot have also investigated the effect of using resins and tar as substitutes for volatile matter, in order to improve the coking properties of

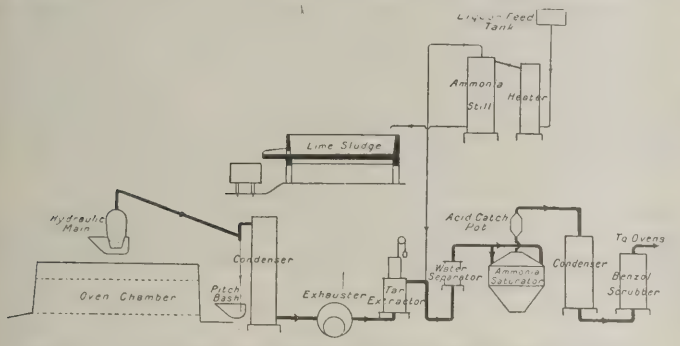

FIG. 2. LAYOUT OF BYPRODUCT RECOVERY PLANT

lean coals. They have found that in both cases remarkable increases in the hardness of the coke can be attained when the correct proportion of the volatile bituminous matter has been ascertained by laboratory trials.

For example, the de Brassac coal referred to above, containing only 11 per cent. of volatile matter, when carbonized with sufficient resinous matter to raise the percentage of volatile in the mixture to 14 per cent., showed a gradually increasing hardness. When the volatile matter reached 28.8 per cent., the hardness test showed 1842 lb. per sq.in. Similar results were obtained by using tar in the carbonizing apparatus.

Finally, Charpy and Godchot investigated the effects of carrying out the carbonization of highly bituminous coals in two stages, the Durham coal used for these tests containing 28.1 per cent. of volatile matter. The first heating was carried out at 450 deg. C. (842 deg. F.) and covered various periods of time. The carbonization was then completed at 700 deg. C. (1292 deg. F.). The results obtained are given in Table II.

The results in Table II prove that a coal which in the natural state is quite useless for producing hard coke, by means of a preliminary heating at 450 deg. C. can be converted into one which will yield a coke of normal quality and hardness.

The importance, therefore, of carrying out preliminary trials with various coals and mixtures, in order to ascertain the best conditions and proportions for carbonization, is emphasized by these tests. The authors claim thus to have indicated a simple and easy method for this purpose. The full text of this valuable

TABLE I. TESTS WITH "DE BRASSAC" AND DURHAM COALS

TABLE II. CARBONIZATION TESTS OF DURHAM COAL

Preliminary Distillation at 450 Deg. C. Duration, Minutes	Per Cent. Volatile in Residue	Quality and Hardness of Coke Obtained After Final Carbonization at 700 Deg. C.
0	28.1	Coke porous and very friable
30	23.5	Coke porous and very friable
60	22.2	Coke porous and very friable
90	21.4	Coke porous and very friable
105	20.0	Coke hard; mean of 3 tests 583 lb. per sq.in.
120	18.1	Coke hard; mean of 3 tests 1387 lb. per sq.in.
150	16.6	Coke hard; mean of 3 tests 356 lb. per sq.in.
165	14.8	Coke powdery

contribution to the scientific side of coking practice will be found in *Comptes Rendus*, 167 (Aug. 26, 1918), pp. 322-324.

Newton Chambers & Co. has erected recently a battery of 37 coke ovens and a byproduct recovery plant in connection with a blast-furnace installation. As this new equipment embodies many of the latest improvements in the Semet-Solvay type of regenerative byproduct coke oven, it appears worthy of a description.

Fig. 1 shows the general arrangement of the coke-oven plant and Fig. 2 that of the recovery plant. Fig. 3 shows sectional elevations of the oven, both longitudinal and transverse.

The slack used is brought from the firm's own colliery by rail and is dumped into an elevator serving a Baum type of coal washery. This washery separates it into nuts, beans, peas and fine coal, the respective sizes and percentages of these grades, obtained from the unwashed slack, being as follows:

Name	Size, In.	Percentage
Nuts	2 to 1¼	15
Beans	1¼ to ¾	10
Peas	¾ to ⅜	10½
Fine	⅜ to 0	57
Dirt		7½

The washed and graded nuts, beans and peas are delivered into separate bunkers and thence discharged into railroad cars and sold, while the fine coal, amounting to 57 per cent. of the total, is passed on to drainers, then to crushers, and finally arrives at the service bunker of the coke-oven battery. This holds 750 tons, or over two days' supply. This bunker is built of

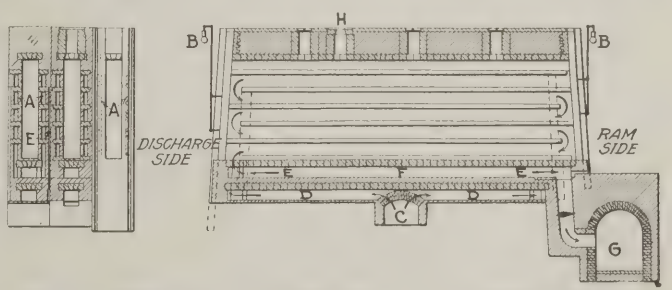

FIG. 3. SECTIONAL ELEVATION OF LATEST TYPE OF SEMET-SOLVAY COKE OVEN

reinforced concrete and is of tank form, with one hoppered outlet.

The washed and disintegrated crushed coal is delivered from this hoppered outlet onto a revolving feed table, from which it is passed by a Robin's belt conveyor to the compression box of the oven-charging machine. This machine is of the combined ramming and charging type and is strongly built, as the ovens are of 12-ton capacity and thus take 50 per cent. larger charges than has been customary hitherto with Semet-Solvay ovens in the United Kingdom. Two stamping machines compress the charge in the box; and by means of an automatic reversing distributor the belt conveyor is

made to deliver its charge over the whole length of the compression box, and thus to promote uniformity in the quality and density of the coke produced.

The ovens are 9 ft. 10 in. high by 36 ft. long, and are of the horizontal flue type, as shown in the sectional elevation, Fig. 3. The air for combustion is preheated to about 300 deg. C. (572 deg. F.) by circulation under the bench of ovens in the flue *C;* and the waste gases from the ovens, with a temperature of 850 to 900 deg. C. (1562 to 1652 deg. F.), are drawn off by the main collecting flue *G* and are used for steam raising, together with the surplus gas from the ovens not required for heating the battery.

The quantity of air supplied to the top burner is greatly in excess of the theoretical quantity required for complete combustion, and this excess is heated in its passage along the flue to a temperature of about 1000 deg. C. (1832 deg. F.) and passes with the burned products into the next flue. Here it provides the free oxygen to burn the gas admitted into the second flue. The excess of air in the burned products from the flue above is such that even in the third and any subsequent burners little additional air is necessary to complete combustion. It is gradually consumed in its second and later traverses, without exceeding in total the theoretical quantity. The burned products make five successive traverses in the heating flues, and as they sweep through the flues, increasing in volume and velocity, combustion is gradually completed, with a minimum of burned products, and with what is claimed to be a very perfect distribution of the heat over the whole surface of the wall.

The gases evolved from the coal in the process of carbonization pass through the outlet in the roof of the oven into the hydraulic main, from which they are drawn, under the influence of an exhauster, through condensers and washing or absorbing apparatus, in which they are deprived of the ammonia, tar and light oils which they contain. Thus dried and purified, the gases are returned by the exhauster to the distributing main *B* to be burned—the main part in the heating flues and the surplus at the boilers.

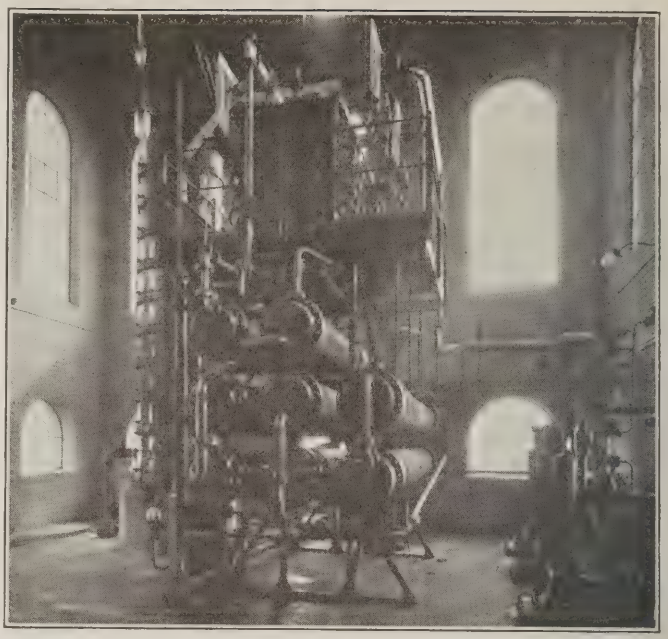

FIG. 4. INTERIOR OF BENZOL RECOVERY PLANT

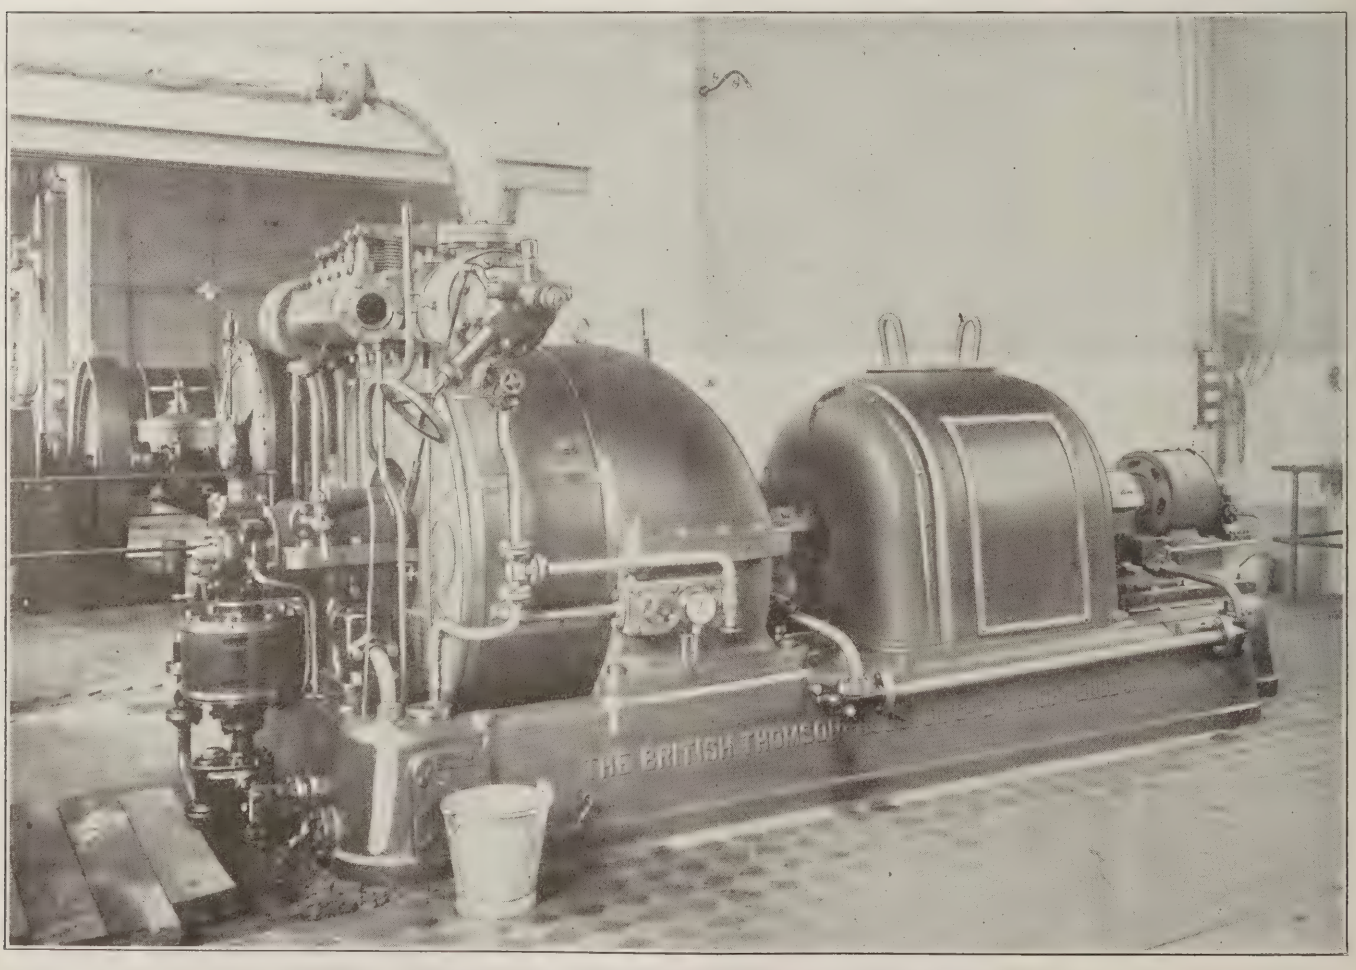

FIG. 5. TURBO-GENERATOR USED AT NEWTON CHAMBERS & CO. PLANT

As regards the capacity of the new plant, it is estimated that as the ovens are of 12 tons capacity and the coking period 34 hours, the output will be 220 tons of coke per day, with corresponding amounts of benzol, ammonium sulphate and other byproducts. The battery of 37 ovens should therefore serve to coke 2200 tons of coal per week (calculated on a dry basis) and the waste gases should raise 26,000 lb. of steam per hour, in the waste-heat utilization portion of the plant. This consists of five double-flued Lancashire boilers equipped with brick-lined fronts and Terbeck burners, and a Green economizer, by which the feed water is raised to 265 deg. F.

Turning now to the arrangement of the recovery plant as shown in Fig. 2—the coke-oven gases are drawn by the exhauster from the hydraulic main, through a series of condensers equipped with horizontal water-cooled tubes, in which they are cooled, and much of the tar and tar water is condensed to liquid form. Only one condenser of the group is shown in the diagram, and only one exhauster. Several condensers and two exhausters are provided, the latter being both steam-driven, although most of the other power required about the plant is provided by an electric generating station.

At this stage the gases are passed through Pelouze and Andouin extractors to remove the last traces of tar mist, and on issuing from these they possess a temperature of about 30 deg. C. (87 deg. F.), and still contain about one-fourth of their original ammonia, the other three-fourths being found in the tar water and liquor. The ammonia is separated from this liquor by distillation with lime. The combined gases, after cooling and equalization of temperature, are passed through a "separator," in order to extract some of the water vapor, and are then bubbled through sulphuric acid in the saturator in order to obtain ammonium sulphate. The crystals of this salt are removed as they are formed, by an air ejector, and after draining are dried by centrifugal action.

The lime liquor that flows from the ammonia stills is allowed to settle in large tanks. The clear liquid is used for quenching the coke while the lime sludge is discharged into wagons and is sold to farmers for agricultural use.

The gases that escape from the saturator, carrying the benzol vapor, have first to be recooled. For this purpose they are passed through a series of six Reutter condensers, equipped in such a way that the cooling water can be used either in parallel or in series. The cooling effect can thus be varied effectively, according to the temperature at which the gases enter the condensers.

The cooled gases are then passed through a Solvay type of benzol scrubber, consisting of a number of tray compartments, the adsorbing oil being fed in at the top and the gases entering the scrubber at the bottom. The effectiveness of this "stripping" operation depends upon the temperature at which the gases enter the scrubber, upon the quality of the wash oil used, and upon the number of tray compartments with which the apparatus is equipped. Good design and management are also necessary to obtain the best results. The benzol is finally separated from the oil in a Solvay type of still, from which oil is returned to the scrubber for further use.

The electrical apparatus that provides all the power and light required consists of a 500-kw. steam turbo-alternator, the turbine being of the three-stage, high-pressure Curtis type, running at 3000 r.p.m. and consuming 20.2 lb. of steam per kilowatt-hour. This figure covers all losses in the generating plant. The

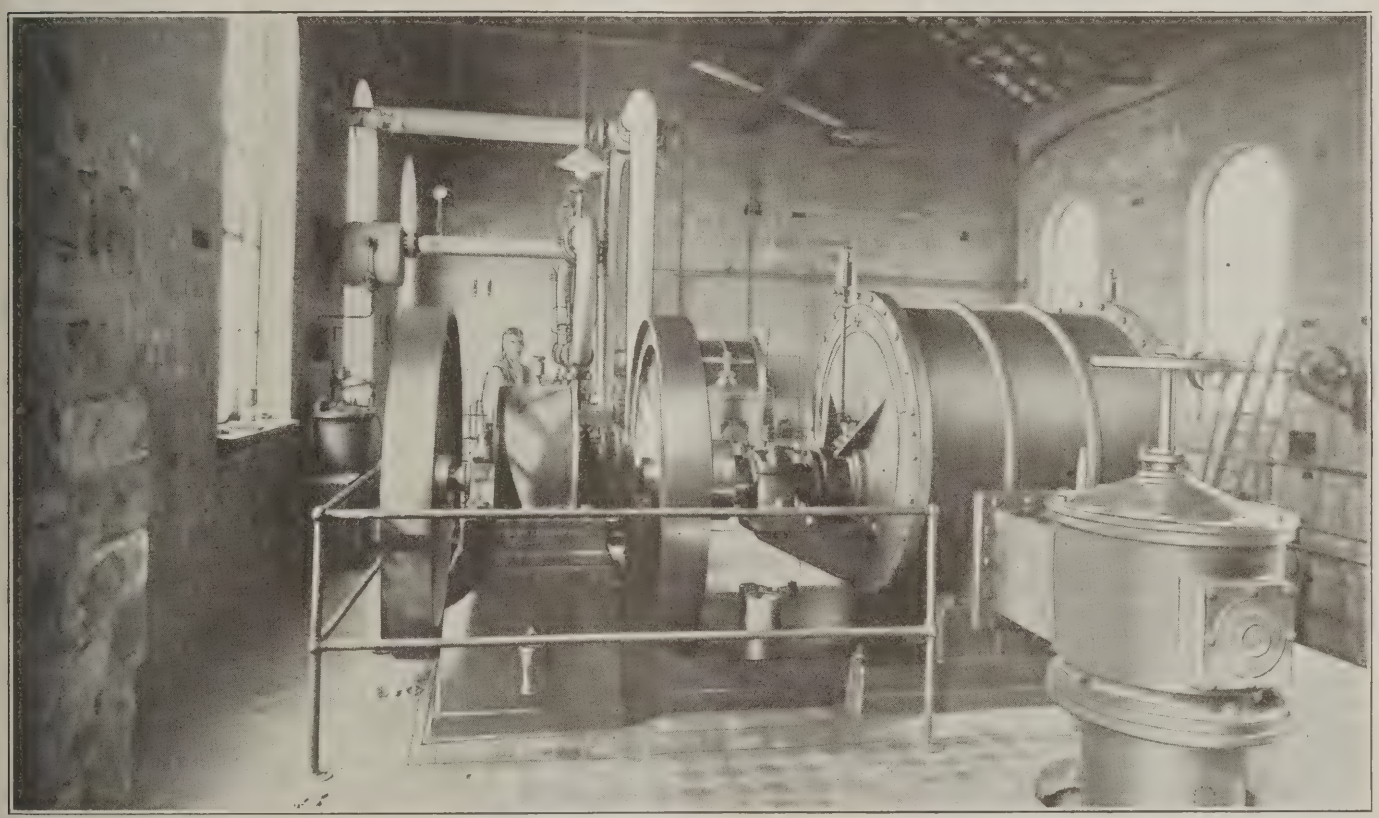

FIG. 6. VIEW OF THE INTERIOR OF THE EXHAUSTER HOUSE

three-phase current is generated at 3300 volts pressure, and is transformed to 550 volts for use in driving the machinery used in the washery and coke-oven plant. Fig. 4 shows the benzol recovery plant, Fig. 5 the turbo-generator and Fig. 6 the exhauster.

The fact that a washed fuel that has been stocked for some time in the open, and thus exposed to atmospheric influences, loses some of its coking qualities has been long known in the coking world. Should the use of stocked coal be necessary, in order to keep any byproduct coke-oven plant in operation, it is better to employ a coal that has not been submitted to a preliminary washing.

The Influence of Moisture upon Byproduct Coking Results

The cause of the greater loss of coking qualities which a washed coal undergoes by storage is the more rapid oxidation change which occurs when the coal is moist, this acceleration of oxidation being caused partly by the higher temperature which reigns in the interior of the stocked heap of coal, and partly by the action of the water in penetrating cracks and crevices of the coal, thus exposing fresh surfaces of the lumps to the action of the air, as the moisture evaporates and the coal breaks into smaller pieces by disintegration.

For immediate use, however, washed coal is better than unwashed for coking purposes, since not only is it possible to reduce the ash and dirt considerably by the process of washing, but this process enables the coke-oven manager to introduce the coal into the coking ovens with the most advantageous amount of water—namely, 9 to 12 per cent. Below 9 per cent., the yield of byproducts is reduced considerably, while above 12 per cent. the loss of heat and damage to the walls of the coke oven are excessive. Coal in its natural condition seldom contains more than 5 per cent. of moisture when delivered to the consumer (unless it happens to come from a very wet mine). It follows that the best percentage of moisture in coal intended for coking purposes, can only be attained by artificial means. A washing plant is therefore a necessary adjunct to the modern coke-oven installation, for in such a case the percentage of moisture in the washed coal is under the control of the coke-oven manager, and by good plant design and management it is possible to have always a good supply of washed coal on hand testing between 9 and 12 per cent. of moisture.

If coal is left too long after washing the moisture will drain away and the washed fuel will show only 5 per cent. or less of water, so that care and organization are required if the coal when charged into the ovens is to test within the limits named above. As proof that a washed slack, if left to drain, will dry down to quite a low percentage of moisture, the following tests made in my own laboratory, upon washed fuels from the South Yorkshire coal field may be quoted:

No. of Sample	Percentage of Moisture	Percentage of Ash	Calorific Values of Dry Fuel
1	4.70	3.30	14,787
2	2.05	5.50	14,626
3	1.83	4.85	14,637
4	2.75	3.25	15,048
5	5.73	5.80	14,387
6	5.10	5.70	14,385

With regard to the effects of moisture upon the yield of byproducts, the explanation for a higher yield of ammonia appears to be that the larger amount of moisture to be evaporated keeps down the oven temperature and thus prevents decomposition of the ammonia by heat; and that the moisture evaporated condenses with the tar and washes the ammonia salts out of it during its condensation to liquid form.

Two other advantages of charging into the ovens coal containing from 9 to 12 per cent. of moisture are that it is then easier to obtain compressed cakes or blocks of sufficient strength to resist the mechanical stresses of charging; and also that the heat of the oven during the charging operation is expended in drying the outer layers of the block, and there is consequently less escape and loss of gas than when a drier coal is employed for charging the ovens.

As regards the best method of sampling and testing the coal for moisture, it is necessary to point out that to obtain an accurate sample of a large heap of wet fuel is not at all an easy matter, and that the results of the test when obtained are only approximate. The most reliable sample can of course be obtained when the coal is being stamped into the box of the charging machine.

If the coal is sampled from the heap or from storage bunkers, it will be necessary to take quite a large number of shovelfuls from various parts of the heap or bunker, and to follow in general the plan of sampling, described in the Bureau of Mines Bulletin No. 116, on this subject.

It will also be necessary to quickly crush the sample of the fuel so obtained down to pea size. One pound of this rough sample should then be weighed out upon a tarred soup plate or other container and be placed under cover in some warm place such as upon some part of the brickwork of a boiler setting, where the plate and its contents will attain a temperature of 110 deg. C. (230 deg. F.) and with frequent turning over of the fuel kept at that temperature for 2 hours. The loss of weight in grams, divided by the factor 4.54, will give the percentage of moisture yet remaining in the sample being tested.

After some experience in the rate at which the stock of each class of washed fuel drains and dries, the coke-oven manager will be able to tell, to within 1 to 2 per cent., when the coal is ready for use. The appearance of wetness varies greatly with different coals, and a determination of the moisture (as described above) is the only really safe indication of the amount of water actually present in the fuel at the time of charging.

Large Tonnage of Pyrite Available

A production of 1,456,000 tons of coal pyrite could be made available in the East and Middle West if a price of 20c. per unit could be obtained for the material f.o.b. at the mines. The estimate, made by the Bureau of Mines, covers only recoverable pyrite with a sulphur content of more than 40 per cent. and includes only those mines that could produce 1 per cent. or more of their coal production as coal pyrite. The estimate is divided as follows:

	Tons per Year
Kansas	125,000
Missouri	175,000
Iowa	140,000
Illinois	238,000
Indiana	250,000
Kentucky	25,000
Tennessee	56,000
Michigan	12,000
Ohio	235,000
Pennsylvania	200,000
Total	1,456,000

Comparison of Bituminous and Anthracite Statistics for Pennsylvania—1918

By R. Dawson Hall
Associate Editor, *Coal Age*

A COMPARISON of the anthracite and bituminous coal industries in the State of Pennsylvania will possibly remove many misconceptions. It will be noticed from the table that the bituminous production in that state alone is 78 per cent. larger than the output of the anthracite mines. The amount of bituminous fuel shipped as coal is not in equal proportion because a large amount of the bituminous coal—18.24 per cent., to be exact—was used in 1918 for the manufacture of coke. However, the bituminous coal shipments exceeded the shipments of anthracite coal by 60 per cent.

The anthracite region has nevertheless some figures larger than any the bituminous region can advance. Though the bituminous field produces 78 per cent. more coal, the anthracite field uses 2.5 times as much coal in securing its quota. This important fact may be put more plainly as follows: The anthracite mines use 0.103 tons, or 205.4 lb., of coal per ton produced for power purposes. The bituminous mines use only 0.023 tons, or 46 lb., per ton of output. Thus the bituminous mines are 4.46 times as sparing in the use of coal for power as the anthracite mines.

Probably much of the difference cannot be avoided, for the amount of water to be pumped, the height of the lift, the length of the hauls, the hoisting and preparation costs are all against the anthracite region. But in this connection it must be remembered that the bituminous mines do much of their cutting by machine, whereas only a comparatively small amount of anthracite is thus cut. However, the coal used for power at the coke ovens in the bituminous regions in a degree balances the use of anthracite for fuel preparation in the hard-coal region.

In both the anthracite and bituminous regions the poorer coal is supposed to be used exclusively for steam-raising, but at most of those mines which do not have automatic stokers the better coal is used quite frequently; and the higher officers of the company do not really know in most cases what kind of coal is actually used in the raising of the steam. In both bituminous and anthracite mines the boiler equipment is usually out of date, though nowhere is that equipment as ancient as in standby plants of the latter region.

It may well be surmised that the large amount of coal used in the anthracite region arises in part from incomplete electrification. Long, improperly protected steam lines waste large quantities of good fuel. In many cases coal has to be hauled long distances on the surface to reach the breaker, and haulage of this kind when not electrical involves the use of much coal of good quality. The anthracite region needs to transmit its power electrically. The record suggests, if it does not prove, that the need is urgent for further electrification. Certainly efficiency has plenty of ground to work on at mines where one ton in ten is used for power purposes.

The tonnage of coal per employee in the bituminous region during 1913 was 837 tons, but the number of days worked was only 232. It is a big improvement when, as in 1918, the average man puts out 1296 tons even though he has the advantage of steadier work. The anthracite region during 1913 put out 520 tons per man, the number of working days being larger; namely, 257 as against 232 in the bituminous region. During 1918, with the impetus resulting from the war, the production per man rose to 974 tons.

Do these facts taken by themselves give a true index of patriotism? In 1918 the bituminous region bettered the record per man of 1913 by 54.8 per cent. The anthracite region improved its record 87.3 per cent. and did it with apparently less increase of time.

However, till we know how steadily each section had an opportunity to work, comparisons are unfair. It is well known that in the early part of 1918 the car supply in the bituminous region did not compare with that of the anthracite region.

COAL PRODUCTION, LABOR AND FATALITY STATISTICS OF PENNSYLVANIA, 1918

* Percentage of coke to coal used for coking.

Coal Industry Would Be Hampered by Continued Federal Control

Discussion of continued Federal control of the coal industry leads George H. Cushing, the secretary of the American Wholesale Coal Association, to outline a course which he thinks should be pursued in this matter. He says:

The coal industry is divided into three parts—production, wholesaling and retailing. While each is distinct from the other two, they are as inseparably parts of a common enterprise as are the head, arms and feet of the body. They are one in objective and obligation. Therefore, no safe program for coal can be devised which does not rest upon the sanction and approval of all three.

Our civilization is built around the use of power. The generation of power demands the consumption of coal. Coal is the one dependable and essential fuel. Therefore, the immediate safety of our civilization depends upon an adequate production of coal. Our future safety depends upon the careful use—and hence conservation—of our coal today.

For these reasons the public has deep interest in coal. No program can be adopted safely which leaves the people in ignorance. Therefore, a necessary preliminary to any program is an elaborate publicity campaign. Without it coal is in danger of being misunderstood.

The most potent cause of waste in coal-mine operation is the fact that each existing mine must compete not only with all other existing mines but, potentially at least, with all the mines which can be opened into all the coal lands in the United States. That is, so soon as coal mines become uniformly profitable, enough new mines can be opened into the reserve coal land to throw the industry into practical insolvency. This degree of competition is wasteful of our coal measures because it compels the operator to take only the cream of his coal, leaving unrecovered and unrecoverable in the ground a percentage of his precious deposit.

Such intensely competitive and wasteful practices in production induce equally intensive and wasteful measures in wholesale and retail distribution. Thus the public and the industry suffer together. This practice cannot long endure.

To the end that competition may be kept in limits comparable to those in other industries, I believe:

First, that the Congress of the United States should declare by resolution that, for the purpose of legislation, the extractive industries should be put in a class by themselves.

Second, that, to ascertain what other helpful measures are needed at once in the coal industry, the Congress of the United States should at once provide for an inquiry into the economics of the coal industry; should provide money to defray the necessary expenses of such an inquiry; and should empower the President of the United States to appoint a commission—nominated to the President by the various interests concerned—representing the public, the users of steam coal, the operators, the wholesalers, the retailers and the miners.

It has been fully demonstrated in this and other nations that Federal control or detailed Federal supervision of an industry results in the dwarfing of the economic development of the controlled industry.

The coal industry of the United States is not, in the matter of efficiency, developed to the point where its growth can safely be checked. For years to come, it must be left free to develop and expand into a truly efficient industry through the operation of that kind of moderated competition practiced in all other industries.

Therefore, I believe:

First, that it should be the announced policy of the people of the United States to leave the coal industry free from detailed control or restraint until moderated competition operated upon by enlightened self-interest has developed an efficient industry.

Second, that it should be the announced policy of the Federal Government to build up an educational organization within one of its departments which should study to improve the business methods employed by the coal industry and to encourage the use of these improved methods by the coal companies.

New Contingent Fee Clause Part of All Railroad Administration Contracts

A new contingent fee clause is being inserted in all Railroad Administration contracts. This is the result of opposition to the old clause. The coal industry was importantly represented in this opposition. The official statement issued in this connection reads as follows:

Walker D. Hines, Director General of Railroads, announces that, with the approval of Attorney General A. Mitchell Palmer, he has consented to a modification of the covenant inserted in purchase contracts under the direction of the Department of Justice issued June 18, 1918, prohibiting the payment to agents of fees contingent upon the procuring of contracts with the Government in so far as it relates to railroad contracts.

Since this order was promulgated by the Attorney General there has been a good deal of complaint from railway supply houses that its provisions were working a hardship upon them and that the Government itself was losing the benefits of a system which, previously, had proven both economical and satisfactory in every particular.

Hereafter the Attorney General's order will not affect contracts made between the Railroad Administration and supply houses which, previous to Government control, carried on their business through bona fide selling agencies.

At the suggestion of John Barton Payne, general counsel for the Railroad Administration, the following clause will be inserted in appropriate cases in future contracts:

"Provided, however, that this covenant shall not invalidate a contract obtained through a bona fide commercial representative employed under a general contract covering designated territory and shall not prohibit or penalize the employment of the same agencies, rates and methods of compensation in dealing with the United States heretofore customarily employed by the contractor in the regular course of his business in similar dealings with the railroad corporations."

Government Interested in Development of Inland Waterways

Extensive use of the inland waterways of the country in coöperation with the railroads is urged by the Director General of Railroads in outlining his waterways policy. He believes joint rates should be made and through bills of lading issued. If the railroads are turned back to their owners, Director General Hines favors the continuance of Government operation of the lines established by the Government on inland waterways. He tells what the Government has done in this connection. With regard to the coal-carrying barge line on the Warrior River, he says:

Service on the Warrior River was delayed because of the difficulty in obtaining and equipping available craft. This service was inaugurated December last, chiefly for the transportation of coal. Joint through rates on coal, in connection with the rail carriers in that district, are being actively considered. The present service provides ample outlet for mines directly on the banks of the Warrior River and without rail connection. Equipment to make practicable the carriage of general merchandise by existing craft is now being designed. This will link the water service on the Warrior River with that on the lower Mississippi, and a comprehensive system of joint water, as well as water-and-rail rates between these two water projects is being developed.

For the Warrior River $698,241 has been expended for the purchase of three wooden towboats, twenty-three 500-ton wooden coal barges, three harbor transfer coal barges and six self-propelled steel barges of an average capacity of 825 tons each. Contracts have been awarded for the construction of four self-propelled steel barges, with a capacity of 1800 tons for coal loading, but equipped to load up to 400 tons each of merchandise provided the coal loading is correspondingly decreased. These barges are for service between Cordova and New Orleans.

Bids have been received and contracts are about to be let for three steel towboats for service between Cordova and Mobile.

Contracts have been let for twenty 500-ton wooden coal barges for service between Cordova and Mobile. The aggregate contract price under these contracts for Warrior River equipment is $1,508,300.

Most of the old equipment purchased as above stated, for use on the Warrior River, is now in operation.

The four self-propelled barges for which contract has been let are expected to be completed early in the fall. The three twin-screw towboats for which contracts are about to be let are expected to be completed about the same time. The twenty wooden barges will be completed between Apr. 1 and June 1, and, pending the completion of the towboats above referred to, towboats will be leased to propel these barges.

With regard to the Chesapeake and Ohio canal, Mr. Hines says:

The Chesapeake and Ohio canal was never operated by the Railroad Administration. At the beginning of the season of 1918, on account of increase made by the canal trustees in toll rates and the increases in operating expenses, the Canal Towage Co., which was the only company operating boats on this canal, announced that it proposed to discontinue operations, as it could not pay operating expenses.

In order to avoid the loss of this means of transportation of coal to Washington and vicinity during the acute congestion which then existed on the railroads and the shortage of coal which then appeared imminent if war conditions continued, the Director General of Railroads at first made an arrangement whereby he assumed payment of the canal tolls on coal traffic on the Chesapeake and Ohio canal. Later in the season, in connection with the increases made in rail freight rates on coal, this arrangement was revised so that for the balance of the season the Director General of Railroads assumed the actual deficit of the Canal Towage Co. in operating its boats. This was substantially less per ton than the canal trustees charged for tolls, the Canal Towage Co. under this arrangement paying such tolls.

For the same reasons which led it to pay part of the expense of operating the canal, the Railroad Administration constructed ten new canalboats to increase the tonnage transported via this canal, these boats being leased to the Canal Towage Co. for operation.

The Railroad Administration has made no arrangement with the Canal Towage Co. to pay any part of its operating expenses for the present year. The same emergency does not exist as obtained last year. Arrangements, however, have been made for divisions between the railroad and the canal of the freight charges from the mines to destination which will make it possible for the Canal Towage Co. to operate its boats on the canal during the coming season as heretofore, and the boats built by the Railroad Administration will be operated by the Canal Towage Co. on a rental basis.

Railroads Will Make Public All Details Concerning Coal Contracts

The National Coal Association feels that its contention with the Railroad Administration is more than half won as a result of the following order which has been issued by the Director General of Railroads:

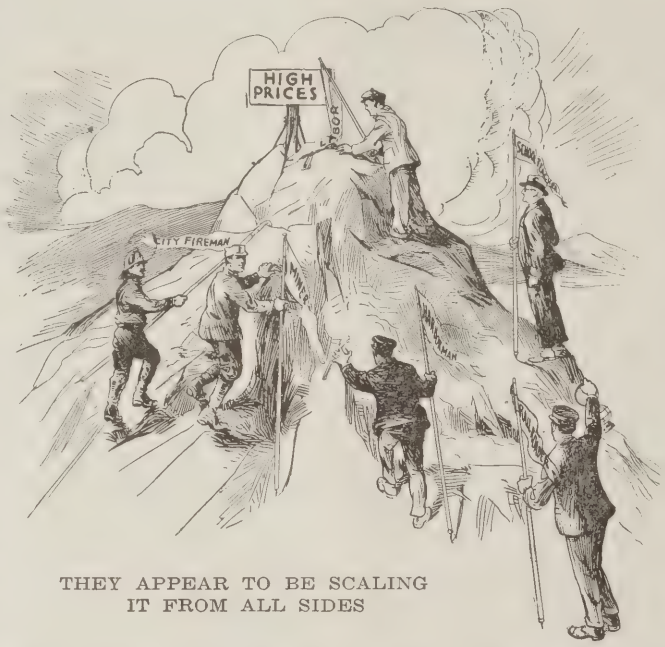
In order to make effective the policy already announced as to publicity in connection with railroad fuel contracts, it has been decided to post on all bulletin boards or in a record book open to the public at the headquarters of the purchasing agent of each railroad under Government operation the following facts: The name of the coal company or coal operator to whom a contract for railroad coal has been allotted by the railroad in question, the price of the coal contained in the contract, the tonnage involved in the contract, the duration of the contract. Through this method the information listed above will be made available not only to coal miners and coal operators, but the public generally.

Government Fuel Yard Soon To Operate

Director Van H. Manning, of the Bureau of Mines, is authority for the statement that the Government coal yard in Washington will begin operations about May 1. When completed this yard, which is located at the New Jersey Avenue freight yard, will be the largest plant of its kind in the United States. It will furnish coal to the Government and municipal departments in the District of Columbia.

The yard covers approximately three acres and will handle about 400,000 tons of coal a year. It has a daily capacity of 1200 tons and storage space for 30,000 tons. The yard will in no way interfere with the local coal dealers, and is solely for Government use. For years the local dealers handled the Government coal, and last year the Department of the Interior thought it could institute economies in coal purchases by handling its own coal, and accordingly did so.

So successful did this coal-handling department prove during the coal shortage in the winter of 1917-1918, that Congress appropriated $432,300 for the establishment and operation of a Government coal yard. George S. Pope is chief engineer of the fuel yard and R. A. Dye chief clerk.



June 3 has been chosen as the date for the annual meeting of the American Wholesale Coal Association. The meeting will be held in Cleveland.

Buyers Have Duties But No Consciences

AWAY WITH double standards! If it is wrong for a seller to "bull" prices by refusing to sell at reasonable figures, it is wrong for the buyer to seek to "bear" prices by declining to buy when a reasonable offer is made. The buyer is the most unconscionable rascal in the body politic, but he does not know it. He ties up business at will, lays workmen idle, evicts the poor, lowers the productive capacity of the world, and inflicts endless misery in the hope of decreasing wages.

A sorry person he is indeed. He has unconsciously bought up the daily press, for the buyers of the country are the readers of the daily papers and the advertisers in daily periodicals. The daily press should be the buyer's father confessor instead of his press agent and confederate. As it is, it keeps his eye closed to the criminality and insensate folly of his way, and spends its unprofitable time inventing stories reflecting on the morality of the producer.

THEY APPEAR TO BE SCALING IT FROM ALL SIDES

As many as 5000 automatic stokers have been installed on American railroad locomotives. It is therefore important that fine coal delivered to the railroads be free from steel couplings, pieces of wood or chunks of slate, which can do as much harm if thrown into such machinery as if dropped into a reciprocating engine.

Labor Still Climbing a Hill of High Prices

REACTIONARIES may be confident—it is an uncomfortable way they have—that prices are going to come down, but prices will keep on soaring just the same. Certain kinds of labor did so much climbing during the war that "alpinism" has become a habit if not a disease. The hill of high prices is being scaled from all sides. Some working men are finding it necessary to get increases to meet the raised cost of living, and some people are still seeking advances in wages for no better reason than because they find it mighty pleasant to receive them.

As a result of the energetic footwork of the laboring classes and their skill with the alpenstock, prices are going to go up, not down. The hill of high prices has been found scalable from all points of the compass. Though steep as the Matterhorn, the veriest of tyros find it easy climbing.

How can prices do otherwise than rise with the prospect of higher freight rates in view, the outcome in part of a $65,000,000 increase granted to railroad labor, which, if the presumably well informed are correct in their surmises, is but a forerunner of another advance that is already under official consideration? The harbormen have been granted a ten-hour day to replace the present day of 12 hours, and they also seek more pay into the bargain. The mine workers, as everyone knows, are agitating energetically for more pay with less work, despite all their many and recent increases in scale. No one expects them to get what they want, but they are seeking it nevertheless. The city firemen, the school teachers and other civil-service employees are looking anxiously for more compensation for their important labors, and in justice to them and to us we must all wish them luck. They will get their increased pay from the taxes, and the taxpayers must get their money from the public, which means, of course, higher prices.

Look where we will we face higher charges for everything. The best way to meet the situation is to buy now before they go higher and buy even if an immediate profit in the use of the thing purchased seems doubtful or entirely unlikely. For instance, now is the time to erect a factory or a house if one will be needed shortly. It may not be possible to rent out either at a profit. To charge a rent commensurate with cost may subject one to all manner of animadversion as an unconscionable profiteer, but one may be sure that rents will be high enough ultimately to more than justify the premature erection.

All kinds of expenditures for materials and construction for which there is prospective use are justifiable and profitable. "Buy it now" is not so much patriotism as hard-headed sense. "Business as usual" and "Let's go" have been suggested as slogans, but good as they are they fail to recognize the situation as it exists. Perhaps a better legend for reviving business would be "Go while the going is good." Today we can buy more cheaply, more readily and more autocratically from the seller than in the near future. Let us beware of delaying our purchases till prices are up. Everybody will soon be regretting that he did not buy in this, the spring of 1919, and will be recalling that prices sagged a trifle at that time preparatory to a well defined, even if not steep, ascent thereafter.

"If We Break Faith with Them Who Die"

OUR SACRIFICE of human lives is over. Some few have paid the debt in the best they had—in human life and limb. There remains only to be paid the more trifling debt in dollars—bills for contracted material and the cost of maintaining the troops still unmobilized. Most of us wish that we could add some small additional amount to the loan for the purpose of making certain that the discharged soldier would get immediate work without the degradation of pleading for it from door to door, without the uncertainty due to the slackness of employment. But the Government is distressingly inactive this year in building, dredging, railroad and highroad making, and in irrigation activities. It appears to be unusually penurious, though in this, of all years, it should be most energetic.

However, we have the war to pay for and the war to finish. The least, we civilians, can give is our money, and that we are only asked to lend. We must not break faith with those who have died. They fell on the field of carnage to maintain our honor, and we are asked merely to lend our money to maintain it. It is a small service, but unfortunately the smaller the service the harder it is to get it accomplished. It is necessary to bribe the people with a promise to pay 4¾ per cent., or 3¾ per cent. without taxation, when the public should be willing to lend its resources gratis seeing that the loan goes to pay for the arms, forged to support those who not only *lent*, but *gave*, their lives in battle.

A little service, this purchasing of the Victory Liberty Loan, but it falls to us and we must meet it. *Coal Age* prints a poster today as a loose-leaf insert showing the appeal of Columbia as the representative of those who sleep in Flanders field, at Chateau Thierry, along the Ourcq and the Vesle, along the slopes of the St. Mihiel salient and in other parts of the Argonne. Quoting (with some changes in personal pronouns) Captain John McRae, of Guelph, Can., who gave his life for our common cause, we may well say: To us

> " . . . from falling hands they throw
> The Torch—be ours to hold it high.
> If we break faith with those who die,
> They will not sleep tho' poppies grow
> In Flanders' fields."

A hundred million people are loudly acclaiming the United States. Let not one of them be found so mean as to fail to give her a full meed of support.

Redfield says prices will fall, but only slowly. Prosperity seekers on the other hand declare that we are due for a long period of stable prices. If either is true why should anyone buy? Rather let us see the facts as they are. Prices are bound to rise, and buying the needful is merely self-defense.

What Is Fuelless in Fuel?

ASKED what are the impurities in coal, we usually say slate, clay, bone and pyrite. This enumeration covers those impurities generally regarded as extraneous, though bone is at least partly intrinsic, and pyrite is possibly rather a segregation from the seam than really extraneous matter. But there are intrinsic impurities—namely, moisture and the incombustible volatile material. The latter is important, for much of the volatile content is really not at all combustible though many widely known authorities still often term all of it "volatile combustible matter," despite the fact that they know much of it has no heat value. Where the volatile matter is large, it is a sure guess that much of it cannot be burned; for in a chemical sense it has been burned already.

Whether impurities are extraneous or intrinsic, whether they are volatile or incapable of distillation, makes no difference; so long as they are unburnable they are useless for heat raising. They will not pay their freight charges, and coal containing them in excessive quantity must be consumed at or near the point of production and cannot enter into international trade.

Sulphur, however, is burnable. It is only partly to be regarded as an impurity, seeing it has a fuel value. Similarly there probably are some hydrocarbons of low hydrogen content which burn with less heat than is given out by those having a high hydrogen content, and so do not have full heat value. The presence of many of these would lower the heating value of the fuel.

Deductions are inevitably made for slate, clay, bone, pyrite, moisture and incombustible volatile matter in the selling price of the coal. Should deductions also be made in the freight rate, which is somewhat absurd, but not by any means unknown, they still would be objectionable for transportation, because the coal which is admixed with these neutral substances does not burn efficiently; and furthermore, the worthless part of the coal just as much as the better material has to be handled and its ashes have to be removed.

It is for these reasons that only the best coal is welcomed abroad. The man who would buy fuel does not want silicate of alumina, pyrite, moisture or carbon dioxide or, possibly, carbon monoxide. Even washed coal with a 5 per cent. ash that has excessive moisture and much oxygenated carbon is not a desirable fuel. It is good enough within a certain radius of its point of production, but it will not serve for an international fuel.

Walter Hines seems to think that wages are too high for him to furnish the soldier boys with employment. He needs to read the slogan "After the war, a job."

Too Great a Levity Among the Augurs

IT IS SAID that the Roman augurs were wont to wink at each other as they passed. So likewise the prognosticating and directing augurs at Washington. The Fuel Administrator threatened a coal shortage next winter, and the Railroad Administrator favored Mr. Garfield with a wink, which later broke into a broad smile. They do not take one another seriously in Washington; but, at that, Garfield was not winking. Neale may yet be stumping the country again in the interest of coal production if labor trouble supervenes or Hines delays any longer his coal purchases.

It was loudly heralded that the Administration was going to see that during the reconstruction or readjustment period there would be work for everyone. The nation fearfully expected the launching of chimerical projects. We heard of them, it is true, but that is all. Now we have to complain that even obvious and needful purchases and projects have been wilfully, or should it be said, ruthlessly delayed.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

American mine workers seem to be taking on a new point of view. In the anthracite region slackness of work has given place to something akin to activity, and the mine workers are better satisfied. In the bituminous region a sort of mental depression in the minds of the employees has resulted from their continued idleness. At first the slackness goaded them into something like defiance. Their complaints were denunciatory in character. The men wanted shorter hours and more pay for the lessened service.

They seemed to believe that all that was needed was that the would-be recipient should ask and he would receive. Now it has dawned on the mine worker that all is not "cakes and ale." He now has taken up the defense instead of the attack. Instead of demanding an increase, he is declaring that he will not stand for a cut.

This is a better attitude. So long as he stands on it he has almost everyone's sympathy except apparently that of the Railroad Administration. A cut in mine labor would open up vistas of possible reductions in all wages. The wage reductionists would hail "the day" which they have been anticipating and toasting. There would be a further period of waiting; business would continue to stand still till everybody had arrived at the conclusion that wage reduction had reached its end.

Wages cannot be much reduced till food comes down in cost. Just now the cost of food is rising. It was 2 per cent. higher in March than in February.

Suppose we had a reduction of mine wages. People might wait a whole year anticipating the fall of more such juicy apples from the tree of present wages, and when they had concluded that no more reductions could come from complaisance on the part of the worker they would then look for further reductions on the ground of a lowering of food prices consequent on the ending of the Government guarantee on wheat. Thus we would have one wait followed by another. It is far better for all concerned to keep wages where they are, for conditions are already shaping themselves to meet them.

Strike To Settle a Long Unsettled Issue

More than 1500 coal miners employed in Arkansas by the Central Coal and Coke Co. of Kansas have struck to compel the company to settle the grievances of its employees at Calhoun, Okla., and in Kansas. An order was issued by Harry A. Garfield, United States Fuel Administrator, directing the men to return to work. Dr. Garfield sent word to John Wilkinson, president of District No. 21, asking him to rescind the order which called out all the 4300 mine workers employed in the Southwest plants of the Central Coal and Coke Company.

Mr. Wilkinson declined to execute the order and said that the strike would continue until a satisfactory settlement had been reached. Dr. Garfield asked that the men submit their grievances for mediation to the labor division of the Administration, under the agreement of July 23, 1917. Mr. Wilkinson replied that the dispute was over machine crews' starting time, that it arose before the inauguration of the Fuel Administration, that it was a question left unsettled by the machine commission designated to make a machine scale and that he "respectfully declined" to rescind the order.

He called Dr. Garfield's attention to the stand of the latter in regard to the McAlester-Edwards Coal Co. dispute at Pittsburg, Okla., where there has been a strike for many months. When the Fuel Administration was asked to interfere in this case, Mr. Wilkinson alleges that it replied that, after investigation, it had found that it had no authority to force the company's compliance with its orders, because the dispute arose before the inauguration of the Fuel Administration.

All of the mines of the Central Coal and Coke Co. at Pittsburg, Kan., are idle, the 1200 miners of the company not reporting for work Apr. 16, following the strike order issued by President Alexander Howat of District 14.

On Apr. 20 H. A. Garfield, in a message to Alexander Howat threatened to revoke the provision of the agreement of November, 1917, between the coal miners and the coal operators, which gave the miners an increase of $1.40 a day, unless Howat ordered the striking miners of the Central Coal and Coke Co. to return to work.

Howat in answer wired to Garfield that he rejected "with contempt the cowardly proposition submitted." The miners, Howat wired, are prepared to fight to the last ditch against the automatic penalty clause, which he denounces as "infamous."

Labor Affairs Across the Sea

The mine workers of the United Kingdom of Great Britain and Ireland have approved by a large majority the report of the Sankey Commission. When the Miners' Federation met in conference, on Apr. 16, it was announced that the ballot on the report had resulted as follows: For acceptance, 693,004; against acceptance, 76,992. The conference decided unanimously in favor of the government's terms, which are the same as those put forward in the majority report of the Sankey Commission.

The British mine workers complaint about housing is amply justified. The Sankey report says the houses are "a reproach to our civilization. No judicial language is sufficiently strong or sufficiently severe to apply in their condemnation."

It was stated in one mining district alone there were 2768 persons living more than five to a single room, 1237 more than six to a room, 510 more than seven to a room and 190 more than eight to a room.

The coal-mine workers of Australia are to receive an increase of 22½ per cent. and the price of coal is to be increased concurrently by the sanction of the government. The premier of New South Wales objects vigorously to the change, saying it would increase the fuel bill of that province a half million of dollars a year. Acting Premier Watt of Australia declares the coal shortage grave and likely to close down industry.

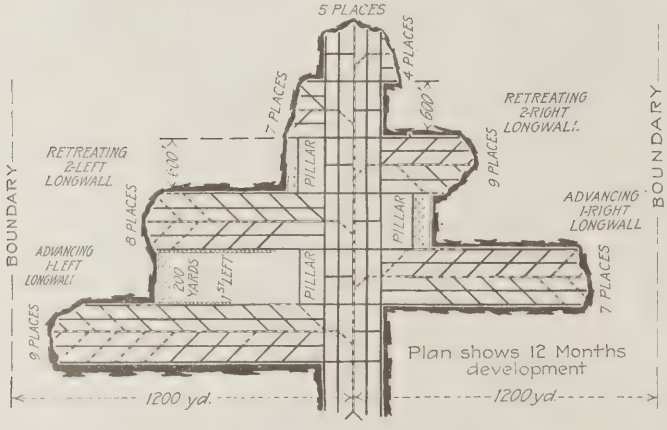
On Apr. 16 it was reported that the railroads, short of coal, had taken off the express trains running from Frankfort and Leipsic to Berlin among many others. The strike, however, was dwindling.

An expert coal council has been created to coöperate with the Economic Ministry in matters of coal production and supply. The council will consist of workmen, producers, consumers, scientists and mine directors and will formulate new laws relating to coal production.

The executive board of District No. 11, which includes most of the Indiana coal field, has protested against a cut in the price of coal, declaring that it would result in a lowering of the mine workers' wage scale. The board sent a communication to W. D. Hines, director-general of railroads, protesting against the proposed reduction in the price of coal to railroads. The miners' officials say that if the railroads are allowed a lower price it would result in the public in general demanding a lower coal rate. At a meeting held in Moose Hall, Clinton, Ind., Apr. 13, the workers of the Clinton coal field showed their approval of the attitude of their chiefs.

Wait Your Turn at the Window, Please

DISCUSSION BY READERS



EDITED BY JAMES T. BEARD

A Modified Longwall System

Letter No. 1—The article of F. A. Pocock, *Coal Age*, Feb. 27, p. 395, describes an interesting modification of longwall mining that appears to have for its chief object the extraction of a larger percentage of coal than is possible by any other method, in my knowledge. The article describes this method as applied to the working of a 3-ft. seam of coal under 80 ft. of cover, which is a shallow depth for longwall working.

While the general plan presented appeals to me as well adapted to the mining of 3-ft. coal, there are some changes or modifications that I would make and which seem to me to be very necessary, in this particular case, owing to the tender roof, which it is said will not support itself over any considerable area. I would suggest that, instead of driving the entries 20 ft. wide, the width should be reduced to as near 12 ft. as is possible and avoid paying yardage. This width would still give ample room for the stowage of the waste due to brushing top or lifting bottom on the roads.

In the plan presented by Mr. Pocock, let me say I can see no advantage in driving the diagonal crosscuts shown in the 5-entry side headings, unless the purpose

PROPOSED LONGWALL PANEL SYSTEM

is to preserve the general plan of the diagonal roads common in longwall workings. No line of dip is shown on the plan, and it is only fair to assume that this is a level seam. In the drawing back of pillars, it is found generally better to cross an old place, as I would say "in parallel," rather than otherwise, and then open up a new face on a new set of pillars.

Now, it is a question in my mind whether it is possible to obtain an output of 3000 tons of coal a day, as is claimed for this system. Let me say I would never figure on cutting 10 ft. deep on a conveyor face, as Mr. Pocock proposes to do with the arcwall machine he uses. It may do for the fast places, but I think it will not answer in a longwall face, using a face conveyor.

Allow me, then, to make a brief estimate of what would be the possible output of the mine, in this case, as based on the development, after 12 months. The dotted line showing the working face at this period, in the plan given by Mr. Pocock, page 395, is, of course, only an approximate line. In the accompanying figure, I have attempted to show what may be taken as a more exact delineation of the work in progress at the end of this 12-months' period.

My plan is drawn to embrace only that portion of the development up to the time mentioned and includes the first, second and third left and right branches, embracing the longwall conveyor faces of the first and second left and the first right. The second right longwall face has not, apparently, been opened at this time, because the third right branch has not been extended far enough to include the 300-ft. pillar protecting the main headings.

ESTIMATED TONNAGE DURING THE FIRST TWELVE-MONTHS' DEVELOPMENT

Now, estimating the output on the assumed basis of Mr. Pocock's figures, with the exception of allowing only a 6-ft. cut on each longwall conveyor face, instead of 10 ft. as he suggests, and counting the number of places in each branch as marked on the plan, taking a cubic yard of coal in place as producing 1 ton of output, gives the following results:

First left branch...	$9(3 \times 20 \times 10) \div 27$	= 200 tons
First left longwall..	$(3 \times 600 \times 6) \div 27$	= 400 tons
Second left branch..	$8(3 \times 20 \times 10) \div 27$	= 177 tons
Second left longwall.	$(3 \times 20 \times 6) \div 27$	= 400 tons
Third left branch...	$7(3 \times 20 \times 10) \div 27$	= 155 tons
Main headings	$5(3 \times 20 \times 10) \div 27$	= 111 tons
Third right branch.	$4(3 \times 20 \times 10) \div 27$	= 88 tons
Second right branch	$9(3 \times 20 \times 10) \div 27$	= 200 tons
First right longwall.	$(3 \times 600 \times 6) \div 27$	= 400 tons
First right branch..	$7(3 \times 20 \times 10) \div 27$	= 155 tons
Total		2286 tons

This shows a total output, at the end of a 12-month development, of 2286 tons. In his estimate, page 396, Mr. Pocock has only included the first and second left and right branch headings, and the first left and first right longwall faces, basing this estimate on a 6-month development. By estimating on three shifts a day, he obtains a total of 3322 tons as the possible output at the end of the first six months. In my opinion, this is overestimating the actual possibilities in practice. I have therefore based my estimate on a single shift and limited the undercut to 6 ft. on the longwall faces, while allowing a 10-ft. cut in the headings.

It occurs to me, after a little further study of this plan, that it proposes to work each alternate longwall face on the retreating system. In that case, the first-left and first-right longwall faces would be worked advancing, while the second-left-and-right longwall faces would be worked retreating. That being the case, my estimate should be 400 tons less than that shown above. However, in practice, it is my belief that two-thirds of this estimated amount, or say 1500 to 1800 tons a day, would be all that it would be safe to expect at the end of a 12-month period.

I am pleased to state that the general proposition appeals to me as being well adapted to give a rapid development in the working of a thin seam of coal. But I would suggest that the depth of cover should not be less than 200 ft. to obtain the best results in longwall working. I believe the principles involved in this method are those that must ultimately be applied to work such seams. W. H. LUXTON.

Linton, Ind.

Perpetuating the Thrift Habit

Letter No. 1—The Foreword in the issue of *Coal Age*, Feb. 6, is a timely presentation of the need of perpetuating the thrift habit. Until recently, it cannot be said that thrift has been a particularly American characteristic. The average American has not chosen to look far enough ahead to create in his mind a desire to save. There are notable exceptions to this rule, however, and the difference between those who have and those who have not formed the habit has proved clearly that thrift is one of the fundamental principles of wealth and independence.

It requires an extraordinary occurrence to revolutionize a fixed habit; and, perhaps, no habit is more fixed among Americans than that of extravagance. Our thrift has been appealed to through our patriotism, in the hour of the country's need. Today, 25 million Americans are feeling a thrill of security through having invested in Government Bonds and War Savings Stamps, while the little Thrift Stamps have made it possible to develop in the youngest child this much-to-be-desired habit.

Could the same noble ideals dominate us, without a recurrence of the world's tragedy, thrift would soon become a characteristic of the average American. No greater blessing could grow out of our overwhelming desire to see the world safe for democracy.

Now that the war is over and there is a tendency on our part to fall back into the old habit of extravagance, the question arises, Is the thrift habit here to stay? No stronger arguments can be presented than those offered in the Foreword to justify the contention that thrift among employees is as good for the employer as for the employed. The man who owns his own home or has his savings invested in Liberty Bonds will not lend an ear to the destructive theories of Bolshevism. On the contrary, the tendency is to make him conservative, loyal to his country and a good citizen.

PROHIBITION A FACTOR IN ADVANCING THRIFT

One of the avenues that has been open, heretofore, to the foolish expenditure of money has been the uncontrolled desire for drink; but the National Congress has now passed the Prohibition Amendment, and we are anxiously watching and waiting to see if it will effectually block this road to extravagance. Experience in the bone dry districts of the past and the failure of local prohibition in places is no proof that nation-wide prohibition will likewise fail. The country is hoping and praying that this will prove an adequate barrier to the great evil of drink.

We must remember, however, that men cannot be forced to save. The appeal to the man must be made through some great channel as that of patriotism to his country, loyalty to his family, and the creation and building up of a strong national characteristic that will be manifest in the thrift of our people. Even great financial panics have not stimulated men to save against the proverbial "rainy day." The present lull in the country's prosperity has made many a person do some hard thinking of how he could have saved money in the past. Let us hope that the lesson taught will be a lasting one and coming prosperity be attended with the growth of thrift everywhere.

Many communities have started plans tending to induce the thrift habit, by making it possible for a man to purchase a home on practically the same plans that he can rent a house. The incentive of ownership of property is a strong factor in perpetuating thrift. The Carnegie Steel Co., recognizing that fact, has sold stock to its employees, on easy terms, and there are doubtless many other ways of appealing to the self-interest of the individual and thereby nursing the thrift habit. The present bond issue offers another opportunity for the investment of savings that engenders citizenship and creates industrious workers and community builders.

THRIFT ENFORCED IN GERMANY MADE THE WORLD WAR POSSIBLE

Notwithstanding all the evil that has been brought to light by the war, as existing in the German nation, we can afford to take one lesson from that people—it is the lesson of *thrift*. It was the thrift habit enforced on the German people that made the undertaking of a war on such gigantic proportions possible. If the same habit of thrift can be united with our other virtues, which the German people did not possess, we may well feel secure as a nation, for all time to come.

In closing, let me say that the perpetuation of the thrift habit among our people will build for this country an enduring prosperity, but we can do it neither by spending money nor by hoarding money, but only by investing our savings. In this regard much depends on mine managers and leaders of our industries.

Thomas, W. Va. W. H. NOONE.

To Abolish Illiteracy

Letter No. 1—I was greatly pleased a short time ago to read the editorial in *Coal Age*, Feb. 20, p. 368, bearing on the subject of the widespread illiteracy in this country. The importance of greater efforts being made to wipe out this condition has been brought to light by the facts recorded in the registry of men in the late war. The records show that the large majority of our alien population are unable to read or write the English language, and a good portion of them are no better equipped in respect to their own language.

As stated in the editorial, Senator Hoke Smith, of Georgia, introduced a bill in the last Congress, calling for the appropriation of twelve and one-half million dollars a year, for four years, for the purpose of overcoming this evil. Let us hope that this bill will be amended, before it is passed, making it compulsory for adult illiterates to attend some kind of a school where they can be taught to read and write the English language, and be made acquainted with the principles of American citizenship and American ideals.

The opportunities offered aliens, through the medium of our institutions, to enable them to acquire knowledge were never better than they are at the present time. The requirements are such that there is no man, however humble, who is unable to avail himself of these op-

portunities and privileges. In every community, this work is being conducted by the Y. M. C. A. and other organizations.

In many coal-mining districts, the larger companies have provided buildings, and teachers to give instruction to all employees who can be induced to attend; and mine officials, almost without exception, have shown deep interest in the work, realizing that the more intelligent their employees become, the more efficient results are produced by their labor.

Need of a Law Fixing a Standard of Learning Among Aliens

It is a matter of regret that so large a portion of these alien employees look with suspicion on any effort put forth by the operators, thinking that their employer's chief object is to rob them. To overcome this difficulty it seems absolutely necessary that a law should be passed that would compel not only aliens, but also home-born adults to acquire a certain standard of learning and knowledge. The present state of Russia today is due to the illiteracy of its people, 90 per cent. of whom are said to be unable to read or write.

It is worthy of note, in this connection, that the Naturalization Court of Luzerne County, Penn., has decided that no applicant will be given his citizen papers before he can read and write the English language, or is making reasonable effort to acquire that ability. If the judges in other counties would take the same stand, it would go far toward inducing aliens to attend the night schools provided for their benefit.

The success and prosperity of every operation is largely measured by the standard of learning among its operatives. In order that everything shall work to the best advantage, each employee must be able to think and act for himself. Men that cannot read must depend on what is told them by those who can, and they naturally become the tools of their informants. It is safe to say that this condition is the primary cause of a majority of our strikes and disputes in mines and factories. A large portion of the workers are unable to read and think for themselves, and fall under the influence of agitators who can see but one side of the question.

Our thanks are due to Senator Hoke Smith for his efforts to wipe out illiteracy from the country. Twelve and a half million dollars spent annually for this purpose cannot fail to bring results in time. Money spent to uplift and educate citizens is money well invested, both from a humane and an economic standpoint. Let us do what we can to advance the cause.

West Pittston, Penn. Richard Bowen.

Certification and Safety

Letter No. 3—I wish to refer to the excellent letter of James Touhey, *Coal Age*, Feb. 20, p. 374, in which he has emphasized the need of arriving at a definite answer to the question of certification of mine officials, which was recently discussed by the Coal Mining Institute of America, in their meeting at Pittsburgh. It certainly is disappointing, to say the least, that no conclusion was reached in that discussion; but, on the contrary, there developed a wide diversity of opinion.

While it is possible that the discussion of the question in *Coal Age* will reveal some differences of opinion, I am sure that, in this as well as in other important discussions relating to coal mining, facts and principles will be spoken that will be a benefit to the coal industry. The suggestions offered may not always prove alike applicable, but it still remains true that the difficulties of coal mining are brought more into subjection through the knowledge gained by discussion.

Referring to the question of the uncertification of mine officials, which was made legal by an enactment of the Pennsylvania Legislature, the action of the lawmakers seems to have been founded on the theory that a man, thoroughly tried in the mining game and found to be efficient and reliable, should be permitted to assume the duties and responsibilities of the office of mine foreman, whether or not he has been able to secure the certificate of the State Mining Board.

Results Realized the Best Guide for the Future

In questioning the wisdom of this act, we must be guided by the results that follow in its wake. If the statement is true, as reported made at the Pittsburgh meeting, that "the employment of 28 uncertified men, in one inspection district alone, was largely responsible for the increase in the number of mine accidents in that district," it would seem to call for an investigation.

It seems incredible that any operator would continue to countenance incompetency on the part of a foreman in his employ; nor can we understand that the state would permit an attitude of neglect or indifference in respect to the safety of mine workers. While I believe that no operator would knowingly favor practices that are unsafe, it is frequently possible for such practices to be followed in a mine, before they are discovered by the higher officials.

A Plea for Service Certification

Personally, I can conceive of no reason why there should be an uncertified official placed in charge of a mine; or, in other words, why a competent official should not possess a certificate, except by reason of illiteracy. However, if such a one has been able, by service, to prove his competency and responsibility, in the management of a mine, and has shown that he is thoroughly practical, though unable to pass the examination before the state board, it appears to me that there is no valid reason why an operator should not be permitted to place him in charge of the property in which the operator's capital is invested.

No one, it seems to me, will deny that it is better that such a man shall be given charge of a mine, than one who possesses a certificate but has little practical experience in underground work and conditions. It is my opinion, that the thoroughly practical man, though illiterate, should not be denied his place of service in a mine where the company or the operator has confidence in his ability to safely control the operations underground. There is no doubt that the repeal of the present revised law, in Pennsylvania, would eliminate a number of these men and prove a hardship to them.

Where *A* Certificate Should Be Demanded

There is, however, another type of uncertified mine official. It is the man who might easily procure a certificate if he so desired. He has all the advantages of a common-school education and may have passed through the high school. His long experience as a competent mine foreman has, perhaps, given him a high regard for his own ability and inculcated in him a certain con-

tempt for the examination proceedings. This man will often excuse his neglect to enter the examination by stating that he has not the time or inclination to prepare himself for the technical work.

In my opinion, the type of man last mentioned should be legally bound to take the examination and should not be employed as mine foreman until he has secured a certificate. It may happen that the examination of this man, so high-minded in his own esteem, will prove that there are one or more points bearing on the welfare and safety of the men in respect to which his knowledge is deficient, which should cure the man of his egotism.

State Law Must Regard Public Welfare

Not to be misunderstood in regard to this important question, let me say that the state should compel compliance with any law intended for the general good of an industry. I will say that the fact that mine accidents increased in one district, owing to the employment of 28 uncertified men as foremen, should prove sufficient evidence that the repeal of the law that made such employment possible is the only remedy, unless it is shown that the incompetency of these uncertified men reflects on the mine inspectors of the district, who should then be held responsible for their lax interpretation of the law.

It may be that the examination for mine foremen and firebosses' certificates, in Pennsylvania, is a little stiff, in respect to the mathematical requirements. If so, it should be possible to modify the examination in such a way that illiterate or practical men will be able to prove their competency and secure a certificate. I feel that the law should protect the illiterate man who has qualified himself in a practical manner for holding the position of foreman in a mine. It may be that an oral, instead of a written examination, would be better adapted to determine the man's competency in such a case. It is my belief that practical men who can prove their qualifications for the position should receive the state's approval to act as foremen and firebosses in mines. This, however, is a question for the state.

Thomas, W. Va. ESSEX.

Efficiency in Firebossing

Letter No. 12—There is much to be said in regard to securing the highest efficiency in a fireboss's work; it is a question of great importance and should be given careful consideration. However, few realize what an unpleasant and dangerous task a fireboss must perform, until they have had the actual experience themselves.

Where the territory to be examined is large a fireboss comes pretty near to having done a day's work when he has completed the morning examination of his district and has traveled the rough roads, climbed over falls and crawled through small openings on his hands and knees, all the time searching for the dangers that lurk on every hand.

The Firebosses' Time Is Never His Own

The duties of this position are such that a faithful fireboss can seldom call the time his own. His evenings are cut short, because he must go to bed at an early hour, so that he will be ready and fit for work when the time comes to enter the mine in the morning. Should he oversleep, his chances are slim for holding his job, as such neglect on his part would throw the mine idle for the day.

Mention has been made of mine foremen's proneness to look upon the fireboss as "a necessary evil." I must admit that this may be true in some parts of the country, and that the fireboss is not always given credit for the work he has to perform, in the same manner that a good coal hauler or a motorman receives credit for what he accomplishes. Such feelings toward a fireboss only exist where mine foremen and superintendents have never performed the same work themselves and do not realize the real nature of the task.

No superintendent or foreman who has climbed the ladder from firebossing in the mine to his present position fails to recognize that he is *not* securing the greatest efficiency in his fireboss by giving him such work as timbering or tracklaying. There should be, in every mine, sufficient work for a good fireboss to perform and keep him busy during a full shift without going outside of his own routine of business.

The Kind of Work That Should Fall to the Lot of a Competent Fireboss

In a newly developed mine, where there is not much area for a fireboss to cover, I should expect him to perform some other labor after he has completed his examination of the working places. But the kind of work that would naturally fall to him is bratticing, clearing gas from the working faces where it may have accumulated since he made his round in the morning, marking off cross-cuts in rooms and entries and similar tasks.

All matters pertaining to safety and first-aid work should be attended to by the fireboss. He should keep the fire extinguishers in good condition, see that the first-aid supplies are on hand and available for use when needed, and give any needed instructions to the men in their working places.

In concluding, let me suggest that those who would have firebosses do work of timbering, tracklaying, etc., set their alarm clocks and follow the fireboss, some morning when he makes his rounds in the mine. If they would do this for a few months, or even a few days, they would soon become aware of how the work tests a man's physical ability. They would know better, then, what the faithful fireboss undergoes, for which, too often, he receives little credit.

Poston, Ohio. JAMES H. TAYLOR.

Letter No. 13—I too have had a few years' experience in the work of firebossing, and it has forced me to the conclusion that every mining company ought to give all the encouragement possible to this class of their employees. They should be given the incentive of promotion, and made to feel that this will be their lot as often as vacancies occur, providing that they prove to be faithful, sober and reliable men and are capable of filling a higher position.

Kindly permit me to refer to the letter of F. G. J., *Coal Age*, Dec. 19, p. 1133, and say that I fail to agree with his idea that the foreman who puts his fireboss to work digging coal and laying tracks or switches is not developing the highest efficiency of that official, in his own particular line. In another place, the same correspondent says that when a foreman does this he "is off the track, all wheels."

It is my opinion that the fireboss should not be set to work to dig coal; but if the mine is running short-handed any time, I think that a foreman is fully justified in giving his fireboss some work that will employ him during his full shift. I feel that a fireboss, under

such circumstances, should be willng to perform work that is important, after his examination of the mine is completed and, in answer to the question doubtfully asked, "Is the foreman doing his duty to the company or the fireboss?" I would say, Yes!

Let me suggest, here, How can a fireboss expect to become an efficient mine foreman if he does not know how to lay tracks, set timber and perform other work that is necessary to be done in the operation of a mine. In doing this, I do not think that a foreman is lowering the standard of firebossing. On the contrary, he is increasing the general efficiency of the mine by training the next man under him so that he will be able to perform his duties in his (the foreman's) absence from the mine.

The Training a Good Fireboss Needs

The fireboss who has had such training will be better prepared for promotion, because of his ability to perform other work than that in his own particular line of duties. It is important that he should know, from his own experience, how long a time is required for a man to lay a switch, set a timber, or do any other work that may be required of him.

In my own experience of six years of firebossing, let me say that when I had completed my morning inspection I have often acted as roperider, mule driver, tracklayer, machine runner and timberman. But, in all that time, I have never been asked by my foreman to do anything contrary to the state law. Had he made such a request, my answer would have been, "No, I would rather give up my place than to be unjust in my duty to the state and to the miners in my charge." I want to add that, in my opinion, every mine foreman should have come into his position only after five years of practical experience underground and by the fireboss route.

Utah.

Carbon County, Utah.

Lubricating Mine Cars

Letter No. 1—In response to the request for an expression of opinion, from mining men, as to the cost of lubricating mine cars equipped with the average type of plain-bearing wheels, a comparative reference being made to the cost when cars are equipped with roller bearings, I am pleased to submit the following data, hoping to let light in on a subject that has frequently been in dispute:

We operate a drift mine and have in use 420 mine cars equipped with plain bearings. These cars will average 12 mi., each, per day. Our records show that we purchased, during 1918, 6204 gal. of blackstrap oil. Of this amount 1034 gal. were used on the mining machines, which supply was kept at a point nearly a mile from our mine-car oiling station. This fact precludes the idea that any of the oil supply for mining machines could, by any mischance, be included in that used on the mine cars. The balance of oil used for lubricating the cars was 6204 — 1034 = 5170 gal. Our oil contract, for 1918, was 11.5c. per gal. The average cost of lubricating each car, for that year, therefore, was (5170 ÷ 420) × 0.115 = $1.415.

During the year 1918 we worked a total of 240 days, and paid our oiler $4.18 per day, which made a total of $1003.20, and the cost of labor for oiling each car was 1003.20 ÷ 420 = $2.389 per year, which, added to the cost of the oil, gives 1.415 + 2.389 = $3.804 per car, per year.

Now, for the sake of comparison, let me assume that our cars were equipped with flexible roller bearings, instead of plain bearings. In that case, the cost would have been about as follows: I will take the figures quoted by "Observer," in the inquiry to which I have referred, and assume 16 lb. of grease to be required, per car, per year. The market quotation for flexible-bearing grease, in this vicinity, is 17c. per lb. and not 10c., as stated by "Observer," This would make the cost for grease 16 × 0.17 = $2.72, per car, per year.

Greasing vs. Oiling Mine Cars

It takes much longer to grease cars than to oil them, and "Observer's" estimate of 40 days, for greasing the cars, is probably correct. We pay for this work $4.18 a day, which would make the cost of greasing 420 cars, 40 × 4.18 = $167.20, per year, or 167.20 ÷ 420 = $0.398, per car, per year. The total cost for grease and labor is, therefore, 2.72 + 0.398 = $3.118, per car, per year.

Now, the apparent saving by greasing, instead of oiling the cars, is 3.804 — 3.118 = $0.686 per car, per year. In our case, the saving for greasing 420 cars would be 420 × 0.686 = $288.12, per year. Comparing this small saving with "Observer's" estimated saving of $6530, per year, for greasing 500 cars, I might ask, in the language of the street, "Where does he get that stuff?"

View of a Prejudiced Salesman

Quite recently, a demonstrator who represented one of the largest grease companies in the United States called at my office on business. While we were conversing, the mail was brought in, and the issue of *Coal Age*, for February 20, was laid on my desk. I am always especially interested in the *Coal Age* discussions, and my eyes quickly caught this inquiry of "Observer," to which I have referred.

After a cursory glance through the article, I handed it to my visitor and asked for his opinion, it being in his direct line. Taking a few moments to glance through the article, he replied, "Obviously inspired." Such also is my opinion. My visitor was especially interested in the price of 10c. for grease, and informed me that flexible-bearing grease was then selling for 17c., with a possibility of its going higher in a few days.

I frankly admit that our cost of lubrication is low, as compared with many mines that I have visited. However, we hire a competent man and give him the best oil we can buy. He has other duties to perform besides oiling the cars. We have very few complaints from drivers and other men, in regard to stiff running cars, although we occasionally find a dry wheel.

Our practice of oiling cars in broad daylight is a distinct advantage over the practice of performing this work in the dim light of a shaft bottom. I too have seen mines where much oil is wasted; but, in every case, the oiling was being done by a young irresponsible boy. In a mine where haulage is performed over a good track and roadbed, and the rolling stock is kept in good condition, there is little cause for low production owing to delays on the road. Let me close with the remark that it would be interesting to get actual figures on the cost of lubricating flexible-bearing mine cars.

J. S. Gelston, Supt.,

Noblestown, Penn. Fayette Coal Co.

INQUIRIES OF GENERAL INTEREST

EDITED BY JAMES T. BEARD

Surveying in an Inclined Seam

I beg to submit the following question for solution in *Coal Age*. As it is worded it is difficult to understand:

A vein dips 60 deg. to the south and strikes N 70° E. Consider the outcrop of the vein as having an elevation of 3650 ft. At a distance of 500 ft. from the outcrop, a vertical shaft is sunk to intersect the vein, the elevation of the surface at this point being 3601. From this shaft, the mouth of a crosscut tunnel bears S 60° E, 2000 ft., on a vertical angle of —30 deg. This tunnel is driven N 33° W, on a 2 per cent. grade, to intersect the vein. It is required, now, to find the length of a slope driven on the vein, from the foot of the shaft to the head of the tunnel. STUDENT.

Shamokin, Penn.

We believe the accompanying sketch, which approaches an isometric perspective, will make the probable meaning of this question clear. Assume two vertical planes, as indicated by the fine dotted lines in the figure, are passed through the outcrop and the shaft, respectively, and parallel to the strike of the seam, which is N 70° E. This seam dips to the south and the direction of the dip, which is at right angles to the strike, is therefore S 20° E. The inclination of the seam is given as 60 deg.

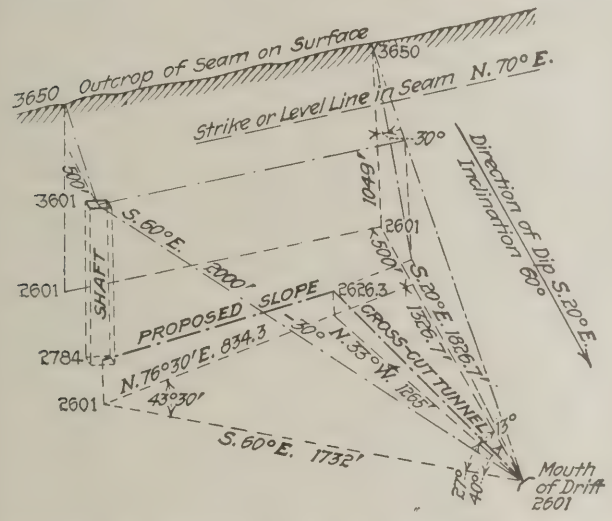


DIAGRAM OF OUTCROP, SHAFT, TUNNEL AND SLOPE

In the space at our disposal, it is only possible to give, in their order and briefly, the successive steps in this problem. The first step is the calculation of the horizontal triangle underlying the crosscut tunnel, the proposed slope and the line joining the top of the shaft with the mouth of the drift. All that is known in this triangle is the direction of two of its sides, as given by the bearing of the mouth of the crosscut tunnel from the shaft, S 60° E, and the direction of the crosscut tunnel itself, N 33° W, respectively. The difference between these two bearings is 60 — 33 = 27 deg., which is therefore the angle included between the two sides of the triangle mentioned. It is necessary, now, to calculate the lengths of these two sides. The first side is the horizontal projection of the line joining the top of the shaft and the mouth of the tunnel and its length is found as follows:

From the reading of the question, the 2000 ft., from the top of the shaft to the mouth of the drift, is to be taken as pitch measurement, on an inclination of —30 deg. This corresponds to a horizontal measurement of 2000 × cos 30 deg., or 2000 × 0.866 = 1732 ft. Likewise, the mouth of the drift is 2000 × sin 30 deg., or 2000 × 0.5 = 1000 ft. below the top of the shaft, making its elevation 2601.

The second side of the triangle is the horizontal projection of the crosscut tunnel. In order to calculate its length, assume a vertical plane is passed through the mouth of the drift and parallel to the full dip of the seam. Projecting the line S 60° E, 1732 ft. onto this vertical plane gives, for its corresponding length, 1732 × cos 40 deg., or 1732 × 0.766 = 1326.7 ft. Adding to this the distance from the outcrop to the shaft, 500 ft., gives 1826.7 ft. for the horizontal distance the mouth of the drift is from the outcrop. The vertical height of the outcrop above the drift mouth is 3650 — 2601 = 1049 ft.

Now, in order to determine the point where the crosscut tunnel intersects the seam, it is necessary to project the line of the tunnel on the vertical plane passing through the mouth of the drift and parallel to the full dip of the seam. This projected line will have a slightly greater grade than that of the tunnel. The increased grade is found by dividing the grade of 2 per cent. by the cosine of the angle between the cross-tunnel and the plane of projection, which is 13 deg. Thus, 0.02 ÷ 0.974 = 0.0205, which is the tangent of the grade angle of the projected line. Then, calling the rise of this projected line at the point where it intersects the seam x, we have

$$\frac{x}{0.0205} + (1049 - x) \tan 30^\circ = 1826.7$$

$$x = 25.3 \text{ ft.}$$

The elevation at the head of the crosscut tunnel is, therefore, 2601 + 25.3 = 2626.3 ft. Now, dividing the given rise, by the percentage of grade of the tunnel gives, for the horizontal length of the tunnel, 25.3 ÷ 0.02 = 1265 feet.

In the horizontal triangle previously mentioned, there are now known two sides and their included angle. The lengths of these sides are 1732 and 1265 ft., respectively, and the included angle is 27 deg. Then, calling the angle that the proposed slope makes with the line joining the foot of the shaft and the mouth of the drift A, it is found thus

$$Tan\, A = \frac{1265\ sin\ 27^\circ}{1732 - 1265\ cos\ 27^\circ} = \frac{1265 \times 0.454}{1732 - 1265 \times 0.891} = 0.949$$

The angle A is, therefore, 43° 30′, which makes the bearing of the proposed slope N 76° 30′ E. The horizontal length of this slope in 1265 × sin 27 deg. ÷ sin 43° 30′ = (1265 × 0.454) ÷ 0.688 = 834.3 ft.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Hoisting Engineers' Examination, Springfield, Ill., Dec. 18, 1918

(*Selected Questions*)

Ques.—What is the breaking strain and safe working load for a good steel hoisting rope 1¼ in. in diameter?

Ans.—The breaking strain of a crucible, cast-steel, 6-strand, 19-wire, hoisting rope, 1 in. in diameter, is 39 tons. Then, since the strength of wire rope varies approximately as the square of the diameter of the rope, the breaking strain of this rope, 1¼ in. in diameter, is

$$S = 39d^2 = 39(1\tfrac{1}{4})^2 = 60.9 \text{ tons}$$

For a moderate depth of shaft, say not exceeding 100 yd., the working load on this rope would be taken, commonly as one-fifth of the breaking strain, or in this case, say 12 tons. In deeper shafts and where a high speed of hoisting is employed the safe working load may be estimated as one-eight or even one-tenth of the breaking strain of the rope.

Ques.—(a) What is steam and how is it produced? (b) What is meant by high-pressure and what by low-pressure steam?

Ans.—(a) Steam is the vapor that is produced when the temperature of water is raised above its boiling point, for any given pressure. In steam-engineering practice, steam is produced by the evaporation of water in a boiler constructed for that purpose and provided with a furnace for heating the boiler.

(b) This question cannot be answered intelligently without knowing its application. In steam-heating practice, "low-pressure steam," is generally understood to refer to a steam pressure not exceeding 15 lb. gage. On the other hand, in steam-engine practice, the terms "low pressure" and "high pressure" applied to steam have a purely local designation or meaning. What would be low pressure, in the operation of some types of engines, would be high pressure for engines of another type. In ordinary hoisting practice, where steam engines are employed, the term "low-pressure steam" may be taken, generally, as steam pressure not exceeding 150 lb. gage, and higher pressures than this might be termed "high-pressure steam;" but there is no actual line of demarkation in engine practice.

Ques.—Define a unit of heat.

Ans.—A unit of heat is the quantity of heat required to raise a unit weight of pure water, at its maximum density, 1 deg., in temperature. There are several heat units in common use, depending on the denomination of the unit of weight and the scale of temperature used. For example, the British thermal unit (B.t.u.) is the quantity of heat required to raise the temperature of 1 lb. of water 1 deg. of the Fahrenheit scale. The French unit is the quantity of heat required to raise the temperature of 1 kg. of water 1 deg. of the Centigrade scale. This unit is called a "calorie." Another unit, sometimes used, combines the two units just given and is called the "pound-calorie." It is the quantity of heat required to raise 1 lb. of water 1 deg. of the Centigrade scale. In each case, the water is pure distilled water, at its maximum density (4 deg. Centigrade).

Ques.—What is meant by water line, steam space, and heating surface of a boiler?

Ans.—The water line of a boiler is the mean water level, which is midway between the lower and upper try-cocks of the water column of the boiler.

The steam space of a boiler is all the space above the water line.

The heating surface is the entire surface of the boiler and tubes or flues that is exposed to the hot gases and flame of the furnace.

Ques.—(a) Define the terms "natural draft" and "forced draft." (b) How is the latter produced?

Ans.—(a) Natural draft, in boiler practice, is the ordinary draft produced by the column of heated gases ascending the stack. A forced draft is that produced by a fan or blower.

(b) Mechanical draft is produced in two ways: What is commonly called "forced draft" is caused by blowing air into the ashpit, which is closed, whereby the air is forced up through the fire. An "induced draft" is often produced by a steam jet or exhaust fan in the flue leading to the stack. By this means, air is drawn through the fire and the draft increased. Both of these forms of artificial draft are often styled "forced draft."

Ques.—What thickness of steel plate is required in the shell of a cylindrical boiler 60 in. in diameter, for a safe working pressure of 100 lb. per sq.in., the tensile strain on the boiler plates not to exceed 8000 lb. per sq.in., and no allowance to be made for joints?

Ans.—Let p = safe-working steam pressure (lb. per sq.in.); d = diameter of boiler shell (in.); t = thickness of metal in the shell (in.); S = allowable stress in the steel plates forming the shell (lb. per sq.in.) Then, the required thickness of the shell in the cylindrical boiler is calculated thus:

$$t = \frac{pd}{2S} = \frac{100 \times 60}{2 \times 8000} = \tfrac{3}{8} \text{ in.}$$

Ques.—What pipe fittings, valves and other attachments are used in setting up and connecting a boiler and engine?

Ans.—First, the feed pipe, with its check valve and two stop valves, connecting the feedpump with the boiler. Second, the steam pipe leading from the boiler to the engine, with its globe valve and non-return stop valve. Third, the blowoff pipes, including both the surface blowoff and that from the mud drum with their valves. The attachments that come with every boiler are the water column, with its try-cocks and gage for ascertaining the water level in the boiler; fusible plugs for guarding against the danger of low water in the boiler; the safety valve for relief of any excess boiler pressure. To these attachments will generally be added the feed-water heater and a steam separator for separating the steam from its entrained water, together with a steam trap for draining off the water that collects in the pipe system.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

American vs. English Coal Output and Prices

A situation of extraordinary gravity has developed in England in relation to coal. Unless it is corrected, and at present this appears to be a thing of great difficulty, the British are certain to labor under heavy handicap in manufacturing and in world trade.

Coal sells today in Birmingham, Manchester, Bradford and other big industrial centers at $10 a ton wholesale. That means a long ton of 2240 pounds. The cost of coal at the mouth of the mine has been climbing steadily. In 1913 it was $2.18 a ton. In 1915, $3.11; in 1917, $4.17½; in 1918, $6.20. Now the miners demand a six-hour workday and an increase in wages. If they get them it is estimated the cost of coal at the mine mouth will average $8.25 a ton.

It must be understood British coal is bituminous. It must be understood also that one-third of all the coal mined in England and Wales has been exported, going to Italy, Spain, Norway, Sweden, Africa, South America and to the innumerable coaling stations mentioned along the lanes of the seven seas.

Pocahontas coal, one of the highest grades of bituminous in America, sells at $2.75 a ton at the mines. This is 40 cents a ton higher than the last price set by the fuel administration. Compare that with the British price and you will appreciate the plight of the British coal producer.

British trade has been buttressed by British control of coal. Thousands of ships went out from British ports with coal and came back with freight—raw material, usually, for British manufacturing establishments to turn into finished goods. Cargo each way lessened the freight rates.

Return Cargoes a Stumbling Block

One of the difficulties America labored under in endeavoring to build up a foreign trade has been that usually it was not able to provide freight both ways.

Now it appears as if America is going to win from Great Britain a considerable percentage of the coal trade of the seas. Great Britain's exports normally have been 80,000,000 tons a year. Today America can deliver coal in South America, Spain, Africa or the Mediterranean cheaper than the British.

Appreciating what this portends, the British Government has taken radical action. It has made a thorough investigation of the coal situation. It has discovered that while the price of coal has been vaulting to heights never reached before in England, production has been decreasing not only in gross quantity, but in tons per man employed. From 274,000,000 in 1913 the yield in 1918 in Great Britain dropped to 218,000,000. Nearly 1,000,000 men are employed in coal mining in the British Isles. In America the production has been increasing enormously until now the gross output is more than three times that of Great Britain. But that is only part of the story. The American coal miner produces three times as much coal per day as the British miner.

The investigation of the British Government shows that mine owners have taken advantage of the public in the war period. Their net profits in 1914 on a production of 266,000,000 tons was $75,000,000. In 1918 on a production of 128,000,000 tons it was $195,000,000.

It practically is certain the Government will take over the British coal mines, close all those where the production costs are excessive and do everything possible to increase production in mines where the costs are moderate comparatively.

This will help, but not enough. The chief difficulty is basic. The British mine is not equipped for economical working as is the American mine, and the British miner is not comparable to the American miner in ability.

Nothing that has come out of the war is likely to play a larger part in promoting America's foreign commerce than this revolution in the coal situation.

America's coal exports have been small. They are likely, as soon as sufficient tonnage is available, to reach to tens of millions of tons a year. That will mean much in lessening the ocean freights and drawing raw materials to America for manufacture. The largest single item, however, will be in making it possible for American industrial establishments, through comparatively cheaper fuel, to meet foreign competition in all the broad markets of the world.

Exports of Coal and Coke During February, 1919

BUNKER COAL

Maryland	21,819
New York	209,619
Philadelphia	23,819
Virginia	69,845

The Department of Mines of Australia has been investigating the coal deposits at Leigh Creek in the hope of finding coal suitable for commercial uses, but so far has not met with success. A method is now being sought whereby the low-grade coal found in Southern Australia can be utilized, as all coal used there at present is shipped from Newcastle, England, and the lack of ships is making it difficult to procure ample supplies.

Low Prices Will Help American Coal Exporters

For a number of years before the war the output of coal in the United States was substantially increasing, per unit of labor, while in England the tendency was in the opposite direction. Also, the costs of production in Great Britain were higher than those in the United States. But by reason of geographical and other advantages England kept a long lead in the export of coal.

The demands of the British miners and the continued diminishment in the output of Great Britain's coal mines have made it possible for the United States to enter foreign markets where England had formerly reigned supreme, says an article in a recent issue of the Philadelphia *Public Ledger*. And in this connection it may not be inappropriate to call to attention certain interesting investigations into the general problem of international fuel prices conducted on behalf of the United States Government before the war.

These investigations related, primarily, to the possibility of diverting trade from the old Suez Canal route to the new Panama route by means of cheap coal. When competition between the Suez and Panama routes, and between American and British industries comes into full play, the price of coal will be a dominating factor. In many cases where the distances between western European and eastern American and Canadian ports, on the one hand, and those of the Orient, Australia, New Zealand and South America, on the other, are anything like equal by the rival routes, coal prices will decide which way the vessels will go; and, of course, whether they use British or American coal on their voyages. If coal prices are much lower at stations on the Panama route than at those on the Suez route, the new waterway will attract the most trade and British interests will suffer to that extent.

Government Started Investigation

Our Government recognized the importance of this coal price question as soon as it was seen that there was a good prospect of the Panama Canal being opened to traffic. Experts were set to work on an elaborate investigation. Various classes of coal were tested for their steaming values, their prices at different coaling stations compared, and estimates as to the price at which American coal might be supplied to vessels using the Panama Canal were prepared.

It was laid down that cheap coal would do as much as low tolls to attract traffic to the new canal and build up the industries of the countries whose trade would be tributary to the canal. It was pointed out that the Government would have to maintain coaling stations at the canal to supply the navy, and that the sale of coal to merchant vessels would simply require larger storage. Further, it was insisted that coal should be supplied at or near bare cost. Since then the Government has established huge coaling stations at both ends of the canal, and it has been decided to increase greatly the coaling accommodation at several ports on the Panama route.

It was established as a result of the investigation that New River coal was only 5 per cent. inferior to best Welsh coal in steaming quality, and from a long list of prices given in a Government publication it appeared that even then, before the Government had got its scheme launched, New River coal was being supplied to ships at St. Lucia, Windward Islands, at about $5.50 a ton, while Welsh coal was about $6 at Port Said. It was stated that while Welsh coal was in the neighborhood of $5.75 at Southampton, Morrisdale coal was only $3 at New York.

It was pointed out that the coaling stations along the Suez route obtained their coal mainly from Wales, England and Scotland, and that the prices varied from 21s. for Durham to 26s. for Welsh at Port Said, whereas it was anticipated that New River coal could be supplied at Colon, or Cristobal, Panama, at least as low as $4.43 by

the time the canal was opened and as low as $3.96 eventually. When the war broke out the Panama Railroad Co. was getting its coal for $2.70 Norfolk, plus $1.39 for transportation to Colon.

By way of illustration, a steamer of 4640 tons gross, making a round voyage of ten knots from New York to Manila by way of Suez, coaling at the usual stations, costing $20,868, was assumed to have made the trip via Panama, coaling at New York, Newport News, Colon, San Francisco, Japanese ports, Moji, San Francisco again, and Colon, and the cost was figured at $18,222—a saving of $2646. The saving was found to be due to the lower prices at Panama than in the Mediterranean and at Japanese ports than at Sebang.

Another Coal Field Dispute in Europe

The coal fields of the Teschen district, in dispute between the Czecho-Slovakia and Poland, present one of the most difficult problems before the peace conference. Both nationalities claim the district is essential to their development. Of the total population of 600,000 about one-third are Czecho-Slovaks and the rest Poles, but if the district were divided on racial lines the industrial district and the railways would be split so as to be of little value to either country.

The Teschen mines are declared to provide the only coking coal available for Czecho-Slovakia and consequently her industries cannot live without them. Warsaw is supplied with gas from the Teschen fields and is dependent upon them for the light, heat and power for the city. Poland, it is stated, has other coking coal fields, but has not developed them.

The Peace Conference Commission on Polish Affairs and the Inter-Allied Commission sent to Poland have been working hard in an endeavor to arrange some plan which will make the Teschen coal available for both countries.

Swiss to Get Saar Coal

The Swiss Federal Council has ratified the economic agreement made with France in Paris, on March 25. Under this agreement, the French government will undertake to deliver to Switzerland each month 60,000 tons of coal from the Saar mines situated on Lorraine territory. The convention stipulates that the French government will assure Switzerland of a supply of steel, to the best of its ability. In return Switzerland shall export to France 25,000 head of cattle, of which 15,000 are to be delivered immediately and the remainder during the present year. The convention will be valid until Dec. 31, 1919.

Poland's Coal Deposits

One of Poland's greatest needs is the modern development and full exploitation of its coal mines, says George Fudakowski, manager bf the Commercial and Industrial Bureau of the Polish National Department, at New York.

Poland's coal fields occupy an area of 2048 square miles and are situated in Dombrowa, Cracow and the Silesian Basin. The deposits in this area are estimated at 94.33 billion tons, of which 61 per cent. is in Upper Silesia; 34 per cent. in Galicia and Austrian Silesia, and 5 per cent. in former Russian Poland. The coal is of good quality, produces little ash, but only the coal of Upper and Austrian Silesia can be transformed into coke. The beds are of considerable thickness and are generally found not far from the surface.

In 1911 the coal produced from these three sources amounted to over 52,000,000 tons, exceeding the annual production of France, which was estimated in 1910 at 41,000,000 metric tons, and represents one-third of the production of coal in Germany without Upper Silesia, the total production of Germany in 1913 being 191,500,000 metric tons.

Mr. Fudakowski says that it is the purpose of the Bureau to present to American investors the development of electrical power in the Polish Silesian coal districts, transmitting it to the main industrial centers in the vicinity of Lodz and Warsaw, a carrying distance of between 120 and 180 miles. This, he says, will permit not only the control of electric power distribution in the mining district, with its numerous industrial establishments, but it will also permit supplying other industrial and agricultural establishments throughout the country.

Foreign Coal Trade Opportunities

A firm in Spain desires to get in touch with shippers of gas and steam coal for that market. Quotations should be given f.o.b. port of departure. Reference. Address Bureau of Foreign and Domestic Commerce, Washington, D. C., or any of its branches, and refer to Opportunity No. 29043.

A wholesale coal dealer in Sweden wishes to purchase steam coal for use in smithys, gas, and for briquets, etc. Quotations should be given f.o.b. Cash will be paid. Reference. Address Bureau of Foreign and Domestic Commerce, Washington, D. C., or any of its branches, and refer to Opportunity No. 29044.

Italians in Straits for Coal

Italian public opinion is very much aroused by the apparent indifference of other countries toward the great crisis that Italy is facing. The coal situation is most serious and unless immediate relief is obtained many of the largest industries will be obliged to suspend activity. The attempt to increase the limited English supply sent to Italy with supplies for various other countries has failed. France has promised to ship 80,000 tons of coal monthly, amounting to about one-tenth of the minimum requirements of Italy. America could furnish the difference, but there is not the necessary tonnage available. Transportation from Germany is also difficult.

Will Take Years To Rehabilitate Pas de Calais Mines

While the securing of coal from the Saar valley will permit some activity in the iron industry in Alsace-Lorraine, Westphalian coal must be had if the industry is to be brought to full efficiency. This is the opinion of Frank H. Probert, the dean of the College of Mining of the University of California, who just has returned from a visit to Europe. Professor Probert, who is consulting engineer of the Bureau of Mines, visited the mining areas in the devastated regions as a member of the Bureau of Mines committee, which is studying the problems presented in the rehabilitation of mines there.

The physical damage done to the iron mines in Alsace and Lorraine, says Professor Probert, was not great. The principal damage has been caused by the pursuit of ore extraction without thought of the permanency of the work or advance development. Much time will be required to replace the steel plants. Most of the magnificent plants in this area were subjected to scientifically conducted destruction. Ample proof of the wilful nature of this destruction is in the possession of the allied military authorities.

Such plants as are left must depend on German coal. Professor Probert is hopeful that an arrangement can be made which will permit of the importation of Westphalian coal for these plants. The absolute destruction of the coal mines in the Pas de Calais section makes it necessary to use either the Westphalia or the coal from the Saar valley. The Saar mines, however, produce a poor quality of coking coal. It will not be possible to operate blast furnaces efficiently unless provision is made for the introduction of better coal.

It will be five years, in the opinion of Professor Probert, before it will be possible to dewater and to reopen the mines in the Pas de Calais section. It will be ten to fifteen years, according to his prediction, before they can be brought back to pre-war production. The flooding of the eastern end of the district offers the greatest problem in reclaiming these mines. It will be necessary to remove some 25,000,000 cubic meters of water. While it is not known how much quicksand has come into the mine, Professor Probert believes that it will be possible to reclaim most of the old shafts and laterals.

Prepayment of Charges on Slack Coal Consigned to Canada

Effective Apr. 15, 1919, Canadian railroads will include in their coal tariffs from frontier points to Canadian destinations the following statement: Freight or other charges will not be advanced on shipments of bituminous slack coal from United States points. All charges through to destination must be prepaid or guaranteed.

1. The New York Central R.R. will not itself guarantee to the Canadian lines collection of charges either to or beyond the frontier on bituminous slack coal.

2. Charges must be prepaid through to destination or satisfactorily guaranteed by shippers and prepayment or guarantee will be passed to Canadian carriers by the New York Central R.R.

3. Reconsignments of bituminous slack coal from original destinations in the United States to destinations in Canada, or from one Canadian destination to another to which the rate from the mines is higher, will not be performed by the New York Central R.R. unless the party requesting such reconsignment prepays or makes satisfactory guarantee of all freight or other charges through to such Canadian destinations.

4. When charges are guaranteed, a statement to that effect must be shown on or accompany the original waybills.

Our Coal Wanted by Swiss

The New York *Tribune* reports:

"Charles A. Anderson & Co. have received cable requests to buy up a large tonnage of coal for Swiss consumers. This is said to be the first time that country has sought to buy coal in the American market, as her logical sources of supply are, under ordinary circumstances, Germany, France or England. The labor troubles in England as well as in Germany, and the wrecking of the French mines in the Lens region during the war, are said to have forced the Swiss to seek fuel supplies in this country. The coal will be forwarded as soon as arrangements can be made for transportation.

An order for 25,000 tons of coal for export delivery has been placed in the Fairmont region of West Virginia. This coal will be shipped to a neutral European country by way of Curtis Bay and is regarded as the beginning of the export movement. One of the large companies in Harrison County started to get out this coal on Tuesday, Apr. 8.

There will be no import duties on coal or siderurgical material into Italy until May 1, according to a cablegram received by the Bureau of Foreign and Domestic Commerce of the Department of Commerce. On account of the coal shortage the consumption of gas has been restricted to certain hours each day. The Commissioner of Fuel stated, in an interview, that the fuel products of the country could be developed to meet its requirements. He also stated that he was in a position to supply 800,000 tons of lignite for railway industrial purposes.

COAL AND COKE NEWS

EDITED BY ALEX MOSS

What Happened in March

[The bracketed figures in the text refer to pages in the present volume and should the reader desire further information he can obtain it by reference to the pages indicated.]

Mar. 3—Senator Vardaman declares that high prices of anthracite during the war were the outcome of monopoly, and that royalties in the anthracite region are too high [XV, 451, 496, 497]—Governors of states and mayors of cities meet in conference at the White House, Washington, D. C., with members of Cabinet and others. They discuss means of reviving business.

Mar. 4—About 16,000 harbor workers in New York harbor go on strike against Macy award of 12-hours' pay for 8 hours of labor and other concessions. They demand an increase of 30 per cent. in the wage rate also.—A. L. Dickenson, financial advisor to the Coal Controller of Great Britain, announces that for the first 8 months of 1918 the profit on mining in that country averaged 86c. per ton on coal having an average cost of $6.05, which is 14.2 per cent. profit per ton. This is over three times average profit in the 5 years ending 1913, when the profit was 24.3c. per ton and the price at the pithead $2.13. Some companies in 1918 were making $1.46 per ton—S. D. Warriner makes reply to the Mar. 3 statements of Senator Vardaman [XV, 494].

Mar. 5—Ten men almost overcome fighting "Jersey mine fire" at Chauncy Colliery of George F. Lee Coal Co. [XV, 510]—Governors and Mayors' conference adjourns sine die after recommending Government activity in railroad construction, the ascertainment by Government of fair prices for staples, opposing price fixing, urging further reductions in freight rates for building materials, opposing reductions in wages till prices fall, asking Federal Government to use its influence in favor of higher street-car fares, impressing on Government need for speed in making war contract settlements and announcing its policy as to excess material on hand, recommending inquiries into wastes of natural resources, calling for continuance of public employment agencies, urging the mustering out of soldiers at point of enlistment, advocating suitable memorials to the heroic dead and recommending that the controllers of natural resources who withhold them for speculative profit or visionary future development be compelled to release them.

Mar. 11—Charles P. Neill gives decision in favor of the cranemen, engineers and firemen engaged in steam-shovel work at the Jeddo stripping of G. B. Markle Co. [XV, 541].

Mar 13—Governor W. C. Sproul of Pennsylvania announces that he has asked Attorney-General W. I. Schaffer what powers are vested in the State Government to inquire into the rise in the cost of anthracite [XV, 553]—Mine workers protest against the Girard royalties as excessively large and as operating to close such mines as have to pay them [XV, 542].

Mar. 18—Policy Committee of United Mine Workers of America advocates 6-hour day, 5-day week, substantial increase on tonnage, daywork, yardage and deadwork prices with Government ownership [XV, 541, 583].

Mar. 19—Fuel Administration urges the buying and stocking of coal to avert coal famine next winter [XV, 579]—Dr. H. A. Garfield desires the National Coal Association to submit in a referendum to all its members a plan of governmental cooperation [XV, 580]—Thirteen United Mine Workers' leaders are indicted for being parties to a shooting at the mines of the E. E. White Coal Co. in November, 1917, the Raleigh, W. Va., grand jury returning a true bill [XV, 630]—Mine workers in Essen region, Germany, adopt resolution in favor of 7½-hour day, to be reduced later to 6½ hours [XV, 630].

Mar. 20—Sankey Commission makes interim report on the wage question in Great Britain advocating more wages, shorter time, regulated prices and government to stand some of the losses in production [XV, 585].

Mar. 25—Conferences between Industrial Board of Department of Commerce and the National Coal Association for the stabilization of price open at Washington, D. C.—Bill introduced into Pennsylvania House of Representatives providing for a 1 per cent. tax on all coal produced in the state [XV, 642].

Mar. 26—Conference between National Coal Association and Industrial Board to provide stabilized prices for coal [XV, 625].

Mar. 27—Conference for stabilization of coal prices ends, the National Coal Association declaring that the United States Railroad Administration is not willing to agree to buy coal at the price to be named but desires to get coal below cost at the expense of the smaller consumer.

Mar. 29—30,000 men on strike in the mines around Essen, Germany [XV, 721].

Mar. 31—Explosion at the Aguilar mine of the Empire Coal Co., in Las Animas, Col. Twelve men are entombed [XV, 686].

Harrisburg, Penn.

At present writing it appears probable that the Pennsylvania legislature will pass a resolution which will provide for an inquiry into the possibilities and advantages of health insurance and that it will abandon the proposed industrial accidents commission. Plans for health insurances and old-age pensions have been studied under action taken in 1917, especially in relation to the possibilities of establishing safeguards of this character against poverty and distress in industrial communities.

These inquiries will now be made more extended and, if present plans do not miscarry, the reports will be presented in the session of 1921 when the proposed commission for a revision of the constitution will also report. Those interesting themselves in the proposed legislation are disposed to make haste slowly, feeling that large changes are in the air and that it would be a mistake to enact legislation that would have to be changed in a few years.

Workmen's compensation is likely to occupy much of the attention of the legislature during the concluding weeks of the session of 1919. Efforts were made in the last session to change the law so as to provide for larger allowances, but it was thought best to let the code of 1915 prove its value or its need for revision by a further test of time. This year, however, the trend of public sentiment seems to favor changes, and the experiences of the last year are held to show the need for alterations. There are not lacking those who are vociferously and persistently advocating a larger measure of compensation.

During the week's recess of the legislature amendments have been prepared, for submission to the legislators, which will give the compensation board power to order direct payment to any dependent minor. It is said that this provision will make it unnecessary to appoint guardians where small amounts only are involved.

The problem as to who shall be deemed to be a dependent is to be settled by the provision that "an employee, who has been a member of the household of his parents and who has within the last six months prior to the accident or death contributed any part of his earnings to its maintenance, shall be conclusively presumed to have been a dependent." The bituminous coal interests have for a long time opposed such a definition.

Compensation which was payable before to a widow, widower, parent or grandparent for a period of 300 weeks will now be lengthened to cover 400 weeks, and it is stipulated that if a widow remarries she is to be given a lump payment in lieu of part of the compensation then payable. It is claimed that the insurance companies, which have much experience in these matters, favor this disposition of the problem.

Pittsburgh, Penn.

In order to provide adequate facilities for a large increase expected in the student body of the school, the School of Mines of the University of Pittsburgh this week has moved from State Hall, in which it has been housed for the last ten years, to buildings on the upper part of the University campus.

The National Retail Coal Merchants' Association met at the Fort Pitt, Apr. 12, and resolved to seek representation in any scheme of distribution that the Government may establish during the period of reconstruction and to encourage early buying of coal.

J. L. Lewis, acting president of the United Mine Workers, declared Apr. 11 that the miners' organization would be obliged to take "drastic action" unless there is a change of policy on the part of Director General Hines. "Since I have been in Pittsburgh," said Mr. Lewis, "I have learned that he is making contracts for coal during April. The custom has been to contract for six months' supplies. This means that the Director General will arrange to get coal during May for less than he paid in April."

Charleston, W. Va.

More progress is being made by the coal industry of West Virginia in building up foreign trade than in getting back the trade suddenly cut off when the armistice was signed. The biggest factor in preventing a return to normal conditions insofar as West Virginia is concerned is the pronounced uncertainty as to just what the future holds, an uncertainty which has only been more keenly accentuated because of the destructive policy of the Railroad Administration. The only fly in the ointment in the growing foreign trade is found in the insistence of the foreign buyer that all coal be furnished in special sizes, no slack being acceptable. This entails the screening of the coal and the storing of the slack.

W. J. Heatherman, Chief of the West Virginia Department of Mines, has announced the appointment of four additional mine inspectors under the terms of the Hale bill re-creating the department. This will bring the total number of inspectors up to 19.

The four new inspectors are W. B. Riggleman, of Fairmont, recently in the mine rescue service, for the Fifth district; J. G. Vaughan, of Montgomery, for the Eleventh district; Edward Nicholson, of Thurmond, for the Twelfth district; and L. D. Vaughn, of Jaeger, for the Eighteenth district.

The 15 inspectors reappointed and reassigned are: S. E. Hawkshaw, of Thomas, First district; W. H. Sandridge, of Grafton, Second district; Evan L. Griffiths, of Clarksburg, Third district; James Golden, of Morgantown, Fourth district; M. B. Coulter, of Moundsville, Sixth district; Eli J. Mason, of Charleston, Seventh district; E. L. Brewer, of Charleston, Eighth district; Zach Evans, of Handley, Ninth district; L. B. Holliday, of Whitesville, Tenth district; R. M. Lambie, of Mt. Hope, Thirteenth district; V. E. Sullivan, of Beckley, Fourteenth district; Thomas Stockdale, of Bramwell, Fifteenth district; H. L. Butler, of Welch, Sixteenth district; J. W. P. St. Clair, of Williamson, Seventeenth district; and R. L. Jenkins, of Logan, Nineteenth district.

Fairmont, W. Va.

The opinion is generally prevalent among West Virginia coal operators that there will be no appreciable lake business insofar as this state is concerned until well toward the latter part of May. There is still a large stock of coal on hand in lake territory from last year's shipments, and from all the information lake shippers can gather there will still be between 3,000,000 and 4,000,000 tons on hand after the middle of May. As large Ohio consumers still appear to have much coal stored so, for the time being, there is not much prospect of a good market in Ohio manufacturing centers.

While somewhat puzzled as to the necessity of the recent order from the Interstate Commerce Commission requiring coal to be purchased by the railroads only upon competitive bids, operators from the Fairmont district insofar as they have had an opportunity to study the order are inclined to look upon it as a part of the effort to reduce the price of coal. Coal producers are not inclined to believe that it will accomplish that object if such is its purpose. The order was transmitted to members of the Northern West Virginia Operators' Association by George T. Bell, the vice president, and reads as follows:

"To All Members—Please be advised that in accordance with section ten of the so-called Clayton act, the Interstate Commerce Commission has prepared regulations requiring the railroads to purchase supplies of all kinds by means of competitive bids, these competitive bids to be publicly opened. The commission has served notice on the railroads and the Director General of Railroads to show cause on or before May 15 why these regulations should not be put into effect immediately. The regulations provide that each bidder will have the right and opportunity to be present in person or by duly authorized agent at the time the bids are opened, and that a tabulated list of all bids will be furnished each bidder or his representative if requested."

Lead, S. D.

Pursuant to the wishes of the citizens of South Dakota, as expressed by the adoption of an amendment to the state constitution at the last election, whereby the state is to engage in coal mining, the Legislature of 1919 passed an act authorizing the appointment of a coal commission with full power to engage in the mining, sale and distribution of coal. The commission is composed of three members, of which the Governor is to be chairman. The act further provides for the acquiring of property by purchase or condemnation and appropriates money therefor.

South Dakota has lignite coal areas extending through Harding, Perkins, Corson, Dewey, Ziebach and Meade Counties, and the amount of available fuel is estimated at two billion tons. Many of the districts are so far distant from a railroad as to make their utilization impractical at this time, but those favorably situated will be investigated with a view to furnishing fuel for state needs. Investigations have been started in Dewey County to determine the extent, thickness of seams and overburden, and upon the result of this work will depend the future of this new industry. Should conditions warrant, the state will enter coal operations on a large scale with steam shovels for both stripping and mining. Much depends on the preliminary investigations, and the field will be thoroughly tested before steps are taken looking to a production of this fuel.

Victoria, B. C.

New coal areas are being developed both on Vancouver Island and in parts of the British Columbia interior. On the Island licenses have been applied for in the Comox district, and it is understood that T. R. Stockett, formerly of the Western Fuel Co., Nanaimo, B. C., is organizing a company in Seattle to develop the coal of these lands. H. W. Treat, of Seattle, also is proceeding with his preparations to open up areas which he has acquired on Chemainus Harbor, apparently confident that the Provincial title which he has acquired will be upheld by the Privy Council. Besides, it is authoritatively announced that coal measures 2½ miles south of Kamloops, B. C., are to be worked again after many years. Some eighteen years ago the blacksmiths of Kamloops and some of the householders of the community used to burn this coal. James L. Brown, of Vancouver, has held the ground for some time. Accompanied by David Evans, consulting engineer, Mr. Brown has returned from an inspection of the property and, as a result of Mr. Evan's examination and on his recommendation, a diamond drill is to be used to determine the extent of the coal measure. The coal is highly bituminous in character and the measures are reported by Mr. Evans to be of the same age and series as those of Vancouver Island.

New York, N. Y.

The War Department will open bids in Washington on May 7 for delivering approximately 2,500,000 tons of bituminous coal during the year beginning July 1 to the various army posts, camps, hospitals, etc., under its jurisdiction throughout the country.

The requirements for the camps, etc., in New York State are given as follows.

Camp Mills, Hempstead, L. I., 19,200 tons run-of-mine; Camp Upton, 30,200 tons run-of-mine; Fort Wadsworth, Staten Island, 720 tons run-of-mine; Watervliet Arsenal, Watervliet, 5894 tons run-of-mine; Army Reserve Dept., South Schenectady, 2900 tons run-of-mine; Fort Slocum, 1200 tons run-of-mine; Stores and Warehouse Division, Governor's Island, 960 tons 2½-inch lump; Fort Terry, 1392 tons run-of-mine; Air Service Depot, Garden City, 10,000 tons run-of-mine; General Hospital No. 38, Eastview, 6000 tons run-of-mine; General Hospital No. 5 and Fort Ontario, Oswego, 4950 tons run-of-mine; General Hospital No. 1, Williamsbridge, 865 tons run-of-mine; General Hospital No. 8, Otisville, 5970 tons run-of-mine; Port Utilities Officer, New York City, 420,000 tons run-of-mine (this tonnage for bunkering transports; only bids specifying recognized classified bunker coal will be considered).

Included in the requirements for New Jersey are: Fort Hancock, 2700 tons run-of-mine; Engineer Depot, Kearney, 10,800 tons ¾-in. lump; Camp Dix, 10,200 tons run-of-mine, Army Supply Base, Port Newark, 8300 tons run-of-mine; Raritan Arsenal, Metuchen, 11,400 tons run-of-mine; General Hospital No. 3, Rahway, 19,520 tons 4-in. lump; Amatol Arsenal, Amatol, 29,500 tons run-of-mine.

PENNSYLVANIA

Anthracite

Yorktown—After an idleness lasting since last February, caused by the light demand for anthracite coal, the Jeanesville and Yorktown collieries of the Lehigh Valley Coal Co. started work on Apr. 15.

Shenandoah—Two men were instantly killed and six other firemen narrowly escaped with their lives when a steam boiler burst at the Locust Gap colliery of the Philadelphia and Reading Coal and Iron Co. The men were employed at the boiler house as firemen and both were buried beneath tons of debris. The boiler left its foundations, sailing 25 ft. into a bank of rice coal. Three other boilers were damaged.

Sunbury—An attempt will be made to induce the County Commissioners of Northumberland County to raise the assessments on coal land from $17,000,000 up to a much larger figure. T. Ellsworth Davies, of Scranton, estimates that there are 3,803,710,965 tons of coal in the county. On this estimate some fearful and wonderful estimates of valuation are being based.

Hazleton—Rumors are current that the Lehigh Valley Coal Co. and C. M. Dodson Co. are negotiating for the purchase of the G. B. Markle Co.'s collieries, the largest independent anthracite operations in the world.

Pottsville—The Tax Revision League has charged the county commissioners with making a "fraudulent and illegal assessment" of the coal lands in Schuylkill County. M. L. Ryan, counsel for the league, seeks to have the assessment set at least $200,000,000 higher than the figure set by the commissioners.

Wilkes-Barre—The air shaft at the Harry E. Colliery of the Forty Fort Coal Co. caught fire and was destroyed on Apr. 8. At that time 500 men were underground and their lives were endangered, but the mine was cleared without accident. The fire lasted several hours and the operation of the colliery may be delayed several days. On the same day in the evening the washery of the Red Ash Coal Co. in Laurel Run Borough, which is a source of employment to 150 men was destroyed by fire. Its value was about $100,000.

Bituminous

Elizabeth—The Pittsburgh Coal Co., which absorbed the Monongahela River Consolidated Coal and Coke Co. has gradually been withdrawing from the river trade. It has just ordered the dismantling of six of its big river boats which were at one time among the most powerful tow boats in western waters. They were used to tow coal from Pittsburgh to Southern ports.

Punxsutawney—The Rochester and Pittsburgh Coal and Iron Co. has closed down the Walston No. 3 Slope mine, which was opened nearly 40 years ago and was the oldest producing mine of large size in this section. It is doubtful if the plant will ever be operated again as the coal is practically worked out. The same company closed ten of their large mines in Indiana County.

Brownsville—The following coal and coke plants in the Lower Connellsville coke region, in Fayette County, have closed down indefinitely during the past week: the Royal ovens (365 ovens) of the W. J. Rainey Coke Co. at Royal Works, on the Pennsylvania R. R. (the mine here is still operating, shipping coal); the Atlas Coke Company (220 ovens) at Helen, on the Pennsylvania R. R.; and the Union Connellsville Coke Co. (140 ovens) at Simpson, on the Monongahela R. R.

Blairsville—Paul Minko, aged about 27 years, the unnaturalized Russian resident at Idamar, who set fire to the tipple of the Idamar Coal Co. Apr. 5, completely destroying it, confessed the crime here and has been sentenced by Judge Langham to pay the costs of prosecution, a fine of $500 and to undergo imprisonment in the Western Penitentiary by separate and solitary confinement for a period of not less than three years and not more than seven years. The temporary tipple has been completed and the mines are again in operation. Minko was incensed at the company because his boarding mistress collected an unpaid board bill through the company's office. By Apr. 9 17,000 ft. of lumber had been used in replacing the burned structure which was already being used for the dumping of coal.

WEST VIRGINIA

Fairmont—Mine No. 11 at Monon belonging to the Jamison Coal and Coke Co., resumed operations on Apr. 10. It is said that export orders via Curtis Bay are the cause of this revival of activity.

Fayetteville—Under the terms of a verdict against the Long Branch Coal Co. awarded in the Circuit Court of Fayette County, May Donald, hardly more than a child, was awarded $19,000 damages. The company after moving to set aside the verdict gave notice of an appeal. The plaintiff's claim was that amputation of her right arm had been necessary as the result of being struck by the truck of a mine car which had become derailed.

A loss of fully $100,000 was sustained when fire destroyed practically the entire business section of Smithers, a Fayette County mining town, though none of the coal plants appear to have been damaged by the fire. The loss sustained is in effect total, as few of the buildings destroyed were covered by insurance.

Elkins—The Weaver mines of the Doris Coal & Coke Co. are now being operated on a full time basis. Other mines in the same section which are also being operated without any break are the mines at Arden. Railroad requirements are said to be partly responsible for the continuity of operations.

Kingwood—The mines in Preston county working in the upper Freeport seam of coal are practically idle on account of lack of business except the Tunnelton mine of the Merchants Coal Corporation and the Car-Diff mine of the Car-Diff Coal Co., both of which are working on Baltimore & Ohio R. R. contracts.

Keyser—At a recent meeting of the Upper Potomac and Georges Creek operators they voiced complaints regarding discrimination by the railroad administration alleging that it hauled coal long distances at a loss in order to secure a low price for coal for its own use. The members also declared themselves in favor of a dissolution of the Tidewater Coal Exchange.

OHIO

New Straitsville—Claiming that they are on the point of starvation because of lack of work, coal miners in this region have appealed to Governor Cox to have pressure brought on the Railroad Administration for a more equal distribution in railroad contracts. The miners point out that some of the mines have been working full time while others have been idle since Nov. 11. They urge a special investigation on the ground that many miners are returning from service and have no work.

ILLINOIS

Duquoin—One of the largest conferences of its kind will be held here Friday, May 9, when representatives of miners, operators and school authorities from all over the southern Illinois district will convene for a joint discussion on vocational training for miners.

Murphysboro—Much improvement has lately been noticed in the work of the mines in the coal fields of Jackson county. Blair's mine at Murphysboro, together with Big Muddy No. 9 and No. 10, have worked practically every day during the last two weeks. No reason is given for this sudden increase, and it is not known how long it will last.

Benton—The Benton Coal Co. broke its record Saturday, Apr. 12, with 2800 tons and 1044 dumps. Its previous record was 2634 tons and 927 dumps. The mine, which is an old one, has greatly increased its output since the new superintendent, Walter Nichols, has been on duty, and the company hopes soon to reach the 3,000 ton mark.

Clifford—The big mine of the Big Muddy Coal and Iron Co. has resumed operations after having been closed down since last November. During the time the mine was closed down extensive improvements and repairs have been made. A new washhouse has been constructed.

IOWA

Sioux City—The Sioux City Coal Exchange will bring suit against Iowa railroads to compel a reduction in rates on the ground that high freight rates are interfering with the city's industrial development. Kansas City, Mo., has a freight rate from the Iowa fields of $1.10, whereas Sioux City consumers have to meet a freight rate of $1.50 to $1.75 a ton.

KENTUCKY

Versailles—The Farmers Union Supply Co., a coöperative corporation started by farmers for the delivery of coal in Versailles, has purchased a coalyard in that town and expects to increase its capital stock from $15,000 to $35,000 in order to finance the new venture. The coal will be brought in by railroad, and the farmers who need supplies will haul it away, the coal being stored in concrete bins.

NORTH DAKOTA

Scranton—The three-unit briquetting plant of the Johnson Fuel Co. at this place is nearing completion and will be placed in commission some time during May. The present arrangement utilizes three Fernholz briquet presses with a daily capacity of 75 tons briquets each. The plant is a large brick structure with sufficient room for eight presses, and it is probable that the full space will be used as soon as conditions permit, giving a daily capacity of 500 tons. No binder is used in the manufacture of the briquet and the fuel finds a ready market. The coal is obtained from the Scranton lignite mine and is recovered by underground and open pit methods of mining. Steam shovels are used in stripping and also for loading the coal and sufficient coal has been uncovered to keep the present plant in continuous operation for several years. The overburden has an average depth of 18 ft., but in places reaches 50 ft. The coal seam averages 18 ft. in thickness and extends through the entire field. Two steam shovels are used at the property, one having a 2½-yd. bucket and the other a 2-yd. bucket.

COLORADO

Denver—William Wardell, a mine foreman, and Joseph Jackson, a fireboss, were blamed for the explosion in the Empire mine, Aguilar, Colo., in a report by the chief inspector. The foreman failed to withdraw the men when the fan stopped, and the fireboss was remiss in reporting the condition of the mine.

WASHINGTON

Chehalis—Extensive operations on coal lands lying west and northwest of Vader, in southern Lewis county, are being secured by people who are said to represent Portland capitalists and others.

Issaquah—A ton of dynamite in the powder house of the Pacific Coast Coal Co.'s coal mine at this place exploded on Saturday night, Apr. 5. The town was rocked, several mine buildings being wrecked and a number of other houses damaged. The loss is estimated at between $5000 and $10,000. No one was injured. John Kerr, night watchman, explains that he was making his rounds and was due to register at 10 o'clock. He was nearing the powder house when he noticed smoke, and stepping closer recognized the spitting flame of a fuse. Kerr turned and ran toward the office, reaching it just as the powder house went up. Besides shattering windows in many of the houses in the immediate vicinity, the side of the compressor house was blown in. It is not thought, however, that the compressor or other machinery was damaged. The timbers at the mouth of the mine were blown down. It is suggested by the evidence that the explosion was deliberately planned, and in this connection it is recalled that the Issaquah Coal Mining Co., as it formerly was known, was controlled by Alvo von Alvensleben, a German interned at Fort Douglas, Utah, and who is said to have been backed by the personal capital of his emperor. Alvo von Alvensleben, it may be stated parenthetically, had coal mining interests in British Columbia, the most notable being what is commonly known as the Jingle Pot mine, Vancouver Island, which still is a producer.

Personals

Harry S. Lewis, formerly sales manager for the Reilly-Peabody Fuel Co., is now manager of sales for the International Fuel Corporation, Pittsburgh, Penn.

W. S. Neal who has been connected with the Standard Pocahontas Co., will be retained by the Central Pocahontas Coal Co., its successor, as superintendent at its No. 3 plant.

T. J. Hudson, of the Chicago Pneumatic Tool Co., Chicago, Ill., has been appointed acting manager of the pneumatic tool sales division, effective Apr. 15, succeeding **F. H. Waldron**, who returns to Minneapolis, Minn., as district manager of sales for the Minneapolis territory.

Mr. Miller, who has at different times been superintendent of various mines of the Pittsburgh Coal Co., has assumed the position of superintendent of the Edna mines of the United Coal Corporation, of Pittsburgh, Penn., taking the place left vacant by the recent resignation of Joseph Maize.

Walter H. Greene has become associated with Whitney & Kemmerer in their New York office, 143 Liberty Street. Mr. Greene was for seven years connected with the firm of Pattison & Bowns, 1 Broadway. He served in the United States Air Service during 1918 and was promoted to lieutenant.

Stanley Gleason has resigned as division engineer of the Pittsburgh Division of the United Coal Corporation. This division has been consolidated with the Somerset division and the work taken care of by F. A. Wyant, formerly engineer of the latter division, whose headquarters have been transferred to Pittsburgh, Penn.

Arthur A. Allan, of Wilkinsburg, Penn., has resigned as assistant general superintendent of the United Coal Corporation of Pittsburgh, Penn., effective May 1. No successor to Mr. Allan has been appointed, but the duties of the position will be taken care of between Harrison T. Booker, general superintendent, and J. D. Martin, chief engineer.

Walter E. Hope, who was director of State Organizations for the United States Fuel Administration, has been nominated to be alumni trustee of Princeton University for five years. His election is assured in June. Mr. Hope, who is a member of the law firm of Masten & Nichols, New York City, was chairman of the special Government Commission sent abroad last Fall to investigate fuel conditions in Great Britain, France and Italy.

Obituary

Charles Baxter Greene, 71 years old, who for 55 years was connected with the coal department of the Delaware, Lackawanna & Western RR. Co., and later with the Delaware, Lackawanna & Western R.R. Co. Coal Department, died at his home in Brooklyn on Apr. 13. Mr. Greene was born in Manhattan and was a descendent on his mother's side of Robert Morris, one of the signers of the Declaration of Independence.

Robert Lee died in Rock Island Ill., after 51 years of service with the Coal Valley Mining Co. He began work with the company Sept. 11, 1856, becoming a mining engineer and holding a position as superintendent of the railroad of the company for a number of years. He was in the mercantile business for himself for some time, but in August, 1875, returned to the coal-mining business as head of mining operations in Mercer County, for the Coal Valley company. He remained until Sept. 11, 1907, 51 years after having taken service with the company. He was succeeded by his son Robert E. Lee, who is now president of the Coal Valley Mining Co.

Industrial News

Chicago, Ill.—Briggs & Turivas, Inc., iron and steel, have opened a New York office at 1805 Equitable Trust Building, to be under the direction of Carl R. Briggs, president of the corporation.

Morgantown, W. Va.—The Monongahela Railway will be compelled to furnish the Arden Coal Co. sidetrack facilities at Round Bottom, W. Va., the Public Service Commission having handed down a decision directing the railroad company to install the siding.

Wilkes-Barre, Penn.—The Hudson Coal Co., has given up its Leggett Creek operations in North Scranton and on May 1 an application will be made to the governor of Pennsylvania for a charter for an intended company to be known as the Leggett's Creek operation in North Scranton.

Columbus, Ohio—The Ohio Blue Ridge Coal Co., which had opened offices in the Brunson Building several months ago, has closed. Allen Pyne, the president, has retired from the coal business and Jay Millar, the secretary, has taken the position of sales manager for the Central West Coal and Lumber Company.

Buffalo, N. Y.—There were seven formal and four informal bids for the city waterworks coal contract, some bidders refusing to conform to the specifications, which were called unnecessarily rigorous. The lowest formal bid was of the Valley Camp Coal Co., of Cleveland, $1.97½ per net ton of 48,000 tons of slack, mine price, on a freight rate of $1.70. The highest formal bid was $2.50, same conditions.

Chicago, Ill.—The Winslow Boiler and Engineering Co., which is about ready to go into the production of its new model "Steamobile" truck, would be glad to receive catalogs from makers of steam boilers and heaters, oil-burning apparatus, steam-engines, apparatus for burning pulverized coal, steam valves, unions and fittings for high pressures and temperatures, machinery and shop tools and equipment. The literature should be addressed to the factory, 530 No. Western Ave., Chicago.

Philadelphia, Penn. — The Lehigh & Wilkes-Barre Coal Co., in its annual report, shows net earnings of $3,069,280 for 1918, after interest and taxes, against $5,431,900 in 1917, a decrease, roughly, of more than 40 per cent. The Barrett Co., a producer of coal-tar derivatives, made its annual report on the same day as did the Lehigh & Wilkes-Barre. It shows that the 1918 net profits, after Federal taxes and charges, were $3,947,783, against $3,728,302 in 1917, or an increase of more than 5 per cent.

Columbus, Ohio—M. S. Connors, Federal manager of the Hocking Valley R. R., announces that there are 14 coal vessels at the Toledo docks awaiting the arrival of coal to be loaded for the Northwest. These boats have a carrying capacity of approximately 125,000 tons. May 1 is the date set for the official opening of the lake trade, although several cargoes have been loaded and are under way. The main lake trade is not expected to be active until after the middle of May. Reports from the Northwest show that the expectancy for lake shipment is 21,000,000 tons as compared with between 28,000,000 and 29,000,000 tons last year.

Columbus, Ohio—A reorganization of the Sunday Creek Coal Co. has been effected by the incorporation of that concern under Ohio laws with a capital of $7,500,000. Of the capital, $6,000,000 is common stock and $1,500,000 preferred stock. The company will take over the properties of the Sunday Creek Coal Co., of New Jersey, the Buckeye Coal and Railway Co. and the Ohio Land and Railway Co. There has been considerable litigation about these properties during the past five years, but now all is cleared up and the new company without any indebtedness and under the management of John S. Jones, of Chicago, will be in a position to carry on the business formerly conducted by the three separate companies.

Philadelphia, Penn.—At the annual meeting of the Anthracite Coal Operators' Association, held at the Bellevue-Stratford, Apr. 3, Percy C. Madeira, of Madeira Hill & Co., was elected president, and John Markle, of G. B. Markle & Co., Inc.; W. L. Connell, of Connell Anthracite Mining Co., and Alan C. Dodson, of Weston Dodson & Co., Inc., vice presidents. Howard W. Perrin, of Susquehanna Collieries Co., is treasurer and W. J. Thompson, of Bethlehem, Penn., is secretary. The office of secretary, formerly held by Alan C. Dodson, will be moved to Philadelphia in the near future. The association has been in existence for three years. It comprises eighty companies operating ninety-nine collieries. Its members produce about 90 per cent. of all the coal mined by the individual operators.

Madrid, Spain—The consulate in Madrid desires up-to-date catalogs representative of all phases of American industry and commerce. The potential importance of the Spanish market in itself and its influence on the Latin-American markets have already been brought to the attention of American manufacturers and exporters. The peculiar situation of Madrid as the geographical, railway, financial and political center of this Spanish market is well known, and the advantage of having such catalogs on file in the Madrid consulate for ready consultation by local distributors to the Spanish trade and by visiting merchants from the Provinces is clearly apparent. Ely E. Palmer is consul.

$60,000 to $85,000. It is understood that the increase will be used for proposed expansion.

Weekly Review

Ending of Port Strike Will Help Tidewater Shipments—Improved Bituminous Output—Industrial Demand for Soft Coal Not Large—Railroad Controversy Not Yet Settled—Anthracite Industry Enjoying Renewed Prosperity

THE ending of the harbor strike in the port of New York brought heartfelt sighs of relief from dealers and consumers who depend upon water carriage for their coal supply. Vessels are being speeded to tidewater as quickly as possible, and the resumption of water-borne fuel shipments to points on the two rivers and Long Island Sound will prove of material benefit to a large number of operations whose output has been embargoed for the past six weeks.

Production of bituminous coal during the week ended Apr. 12 mirrors the noticeable betterment in demand. The total output of the mines of the country for that week is estimated at 7,417,000 net tons, as against 6,967,000 net tons during the week ended Apr. 5.

Demands for coal for industrial purposes are still insufficient in aggregate to keep all the soft-coal mines working full time. Many operations are closed down, while others work only two or three days a week. The mine workers in many regions have petitioned the governors of their respective states to bring pressure to bear upon the Railroad Administration, to the end that the working time at the mines be equalized. At present the anomaly is presented of some mines in a district working nearly full time on contracts for railroad coal, while other operations in the same field are idle because the railroad purchasing agent has placed all the business for his road with a few favored operators.

The railroad fuel problem has served to impede the progress of the soft-coal industry for years. The matter assumes new phases and angles with such frequency that no sooner is one question in controversy settled than another development manifests itself to plague the operators. Like Banquo's ghost, it will not be downed. Latest reports have it, however, that an amicable understanding will be arrived at in the near future.

Industry in general has not yet resumed its maximum activity. As a consequence the consumption of fuel at this time is comparatively negligible when it is remembered that the soft coal operators can produce well over 600 million net tons of coal a year. The good grades of bituminous are finding a ready market, and it is gratifying to record that no idiotic price-cutting, with all its attendant evils, is in evidence. Prices are being held at the former Government figures, and quite a little contract business has been closed on this basis. In short, it can be stated that the soft-coal market is satisfactory, with all indications pointing to a slow but steady improvement.

News from the anthracite field is cheering. Operations that have been closed down for months are now working anew, and if present conditions continue the fear of a coal shortage next winter can be dispelled. The admonishments to householders that they order their coal early seem to be bearing fruit, for the sales of domestic sizes are reported to be satisfactory.

The small sizes of anthracite continue to drag, though the opinion is expressed in some quarters that steam coal will find more favor within the next two months as the result of increased industrial activity. During the week ended Apr. 12 it is estimated that 1,750,000 net tons of anthracite were sent to market, about half a million tons more than the output of the week ended Apr. 5.

WEEKLY COAL PRODUCTION

The output of bituminous coal during the week ended Apr. 12 was a considerable improvement over the tonnage produced during the week preceding. Estimates place the current week's output at 7,417,000 net tons, as compared with 6,967,000 net tons during the week ended Apr. 5. As in previous weeks, the current week's production fell far below that of the same week of 1918, the decrease amounting to 3,300,000 net tons. For the calendar year to date the output is estimated at 120,840,000 net tons, and falls approximately 35,000,000 net tons behind the output during the same period of last year, estimated at 155,308,000 net tons. The average production per working day during the week ended Apr. 12 is estimated at 1,236,000 net tons, as compared with 1,373,000 net tons for this calendar year to date, and 1,765,000 net tons for the preceding year.

The production of anthracite in the United States during the week ended Apr. 12 is estimated at 1,750,000 net tons and exceeds the previous week's production by one-half a million net tons, but falls behind the output of the corresponding week of last year by 120,000 net tons. The total production for the calendar year to date is estimated at 20,693,000 net tons, as compared with 27,434,000 net tons during the same period of last year. The daily average per working day during the current week is estimated at 292,000 net tons, compared with 235,000 net tons for the calendar year to date, and 312,000 net tons for the period Jan. 1 to Apr. 12, 1918.

Carriers' reports for the week ended Apr. 12 shows an increase in loading in all fields with the exception of the Illinois, Indiana and western Kentucky district. In this district the decrease amounted to 1500 carloads while considerable improvement occurred in central Pennsylvania, where the increase over the week preceding amounted to 3063 carloads; in western Pennsylvania, 1450 carloads; in Ohio, 1723 carloads.

Shipments of bituminous coal from the tidewater harbors to all points during the week ended Apr. 12 are estimated at 484,169 net tons, and exceed the previous week's shipments by approximately 14,000 net tons. Compared with the same week of last year, the tonnage moved during the current week was 237,423 net tons lower. Improvement occurred during the week at New York and Baltimore, while at Philadelphia and Hampton Roads slightly less tonnage was moved than was reported during the week ended Apr. 5.

Bituminous coal shipped to New England by tidewater during the week ended Apr. 12 is estimated at 117,478 net tons, and with the exception of Philadelphia's movement of 172 net tons, the tonnage loaded for the week originated at either New York or Hampton Roads. The tonnage loaded at New York exceeded that of the preceding week by 4000 net tons, while Philadelphia's tonnage decreased to practically nothing during the current week, and Hampton Roads tonnage fell behind that of the preceding week by 3600 net tons. The current week's movement was but 43 per cent. of the tonnage loaded during the corresponding week of 1918.

The production of beehive coke in the United States during the week ended Apr. 12 is estimated at 318,458 net tons, and is the lowest production recorded in recent years. This low tonnage was approximately 31,000 net tons below the production of the week preceding, and was but 55 per cent. of the output of the week of Apr. 13, 1918. The large falling off during the current week was localized in Pennsylvania where the decrease, compared with the week preceding, amounted to approximately 27,600 net tons. West Virginia also fell behind slightly, while in the other states little change occurred compared with the week of Apr. 5. The daily average during the week ended Apr. 12 is estimated at 43,076 net tons, as compared with an average daily production for the calendar year to date of 75,504 net tons, and in the same period of last year of 93,684 net tons.

BUSINESS OPINIONS

American Wool and Cotton Reporter—The demand for fine wools at an advancing tendency is a feature of the wool market. It is expected, however, that low wools will also be in demand soon in larger quantities than they are at present. A few of the manufacturers are declining to sell goods more than two months ahead, feeling that values will be greater later. A fair demand for cotton from the mills has been evident during the week under review, but it is not anywhere near as large as it might be. Cotton is really in a strong position until a substantial crop is in sight.

Marshall Field & Co.—Current wholesale distribution of dry goods is running a little below the high figure of the corresponding week a year ago. Retailers were very busy with Easter trade and not so many were in the market as compared with recent weeks. There have been advances in the price of staple cottons and the firm tendency of the market has stimulated business for fall. Orders from road salesmen for both immediate and future delivery were larger than for the same week of 1918. Collections are satisfactory.

The Iron Age—While they wait for a final decision of the question whether the Government will help or hinder the effort to encourage buying of iron and steel, pro-

ducers are doing little new business and are showing no great concern about the course of prices. The widespread propaganda of the Department of Labor and in many lines of trade and industry in behalf of wage and price maintenance has even robbed an open market of some of its old-time terrors. Meanwhile ultimate consumers of such products as wire and pipe are in the market with their small needs, which jobbers are passing on to the mills, but nowhere along the line is any stock being accumulated. On what they are selling, mills are getting in nearly all cases the prices named at Washington on Mar. 20.

Dry Goods Economist—An important development of the week is the new light thrown on the price trend. While retailers are skeptical, and naturally so, of predictions as to higher quotations coming from those from whom they buy, it is certain that due attention should be given to the statement issued by the National Wholesale Dry Goods Association, at its meeting, to the effect that the bottom has been reached. The jobbers also declare that scarcity is apparent in several lines, and in view of this condition they predict not only the maintenance of present prices but also a movement toward higher levels.

Atlantic Seaboard

BOSTON

Little change in generally dull market. Railroad buying awaited with much interest. Prices on better grades so far unaffected. Only scattered sales all-rail. Hampton Roads shippers sadly need orders. Freight rates do not induce buying. Needs of New England this year over-estimated. All-rail demand steady, but less than normal for April. Retailers well supplied with orders.

Bituminous—The market may still be described as generally dull. The past week has shown no significant development; prices and requests continue without material change. The larger buyers are still withholding inquiries and for the next thirty days it is hard to see how there can be any decided move in any direction. Neither all-rail nor in the West Virginia districts can operators show more than 50 per cent. output, and that mark in production is just about met in New England by 50 per cent. consumption on the part of many of the industrials, textiles in particular.

So far prices on the quality grades have remained unaffected by the low figures used in connection with railroad purchases; $2.95 per net ton is a fairly firm price for a large number of coals from the South Fork region in central Pennsylvania, and today it seems to matter little on these grades whether the price sought is for contract or for spot shipment. There are still a few special coals on which higher prices are named. Sales of the latter are confined to instances where the coals are well known and are required because of coking or other preferred characteristics. The grades that sell down to $2.50 have today only a restricted market, so pronounced is the attitude of most buyers in favor of the coals of recognized higher value. Freight rates are so high to this territory that 15c.@25c. on the delivered cost is considered negligible, and as the season advances buying sentiment is more and more discriminating.

All-rail territory has yielded only scattering sales the past fortnight. To find spot buyers the most careful combing is required, and the volume is very light. Those within 50 miles or so of tidewater are also watching developments on West Virginia coals by water. In normal years there have been plenty of opportunities to buy these coals at relatively low cost, and so far a large number of buyers see no reason why this season should not show similar developments. The export demand is not regarded very seriously here, as yet, and it is generally looked upon as too early to take on large tonnages while there are still ample stocks in reserve.

It is certain the Hampton Roads agencies sadly need orders for current shipment. There are large accumulations at the piers, and no snap to the demand from any direction. The number of bottoms loaded for New England is very small, and most of the distributing factors here are simply waiting for something to turn up. A fair market for prepared coal is reported from the west, but this is of help only to those shippers who have outlets for their slack. For run-of-mine there is only a hand-to-mouth demand in this territory from regular contractors, and those only who take their supplies either directly on the seaboard or who are short distances inland. Prices on the basis of $2.75 per net ton f.o.b. mines for both Pocahontas and New River are being maintained fairly well by the larger shippers, but there is quite a tonnage available through smaller factors that can easily be had on the $2.35 basis for both coals.

The lower rates on bottoms from Hampton Roads have not influenced buying, so far as we can observe; $2 is now the freight rate on either steam or barge tonnage from Norfolk to Boston, Providence, R. I., being 25c. less, and it is hardly expected that barges will move later at any material reduction from this basis. For New York loading to points on Long Island Sound rates are firm at $1, mainly for anthracite, but this has a bearing on freights from Hampton Roads. So long as such rates as these can be had for short distances the owners of barges will be unlikely to send them to Norfolk for very much less than $2. There is reason, therefore, for the prediction that Southern water rates are probably on as low a level as will obtain the present season.

Bituminous prices at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net ton as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.80@3.35
Philadelphia, gross tons	4.20@4.90	5.00@5.40
New York, gross tons	4.50@5.25	5.35@5.80
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.65

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.69 @ 5.15 f.o.b. Norfolk and Newport News, Va., per gross ton, according to the shipper, for spot or contract. Alongside Boston the present gross ton range would be $7.15 @ 8.10. It is understood that factors are naming $7.90 per gross ton on cars Boston for distribution inland, through the season.

Anthracite — Demand all-rail is steady and consistent, but by reason of so much tonnage having been taken in March the volume for this mouth is less than would be considered normal for April. Retail trade is remarkably good, and there are increasing indications that consumers in general will make the effort to get their coal early. If this can be done throughout New England there is no doubt it will help very much in the season's distribution of fuel.

NEW YORK

Marine strike settlement creates heavy demand and will result in more coal coming to tidewater. All of the domestic sizes wanted, with egg and stove leading. The anthracite steam sizes holding firm with the market becoming stronger. Bituminous firm with demand good and prices steady. Dealers look for a busy summer.

Anthracite—The ending of the marine strike in this harbor has put the trade on a substantial basis. Demand at once strengthened and dealers were anxious to fill their bins, a majority of which were near depletion after a partial tie-up of shipping for seven weeks.

The settlement of the strike resulted in a rush of boats to the various loading ports. Carrying rates from the harbor are quoted at about 50c., which is a slight increase over the rates in effect before the strike.

With harbor deliveries back to normal shipments from the mines to this tidewater are expected to increase materially within the next week, and the line trade which has been receiving the bulk of the production will be expected to accept a reduced tonnage hereafter.

Trade during the last half of the week was practically at a standstill in this harbor. Shipping was irregular and there was little towing accomplished. Most of the docks were congested either by filled bins and cars or loaded boats waiting to be taken to destination. The situation at the upper docks was somewhat better than at the lower docks because of the shorter towing distance to the dealers' yards and the ability of the railroads to deliver barges with their own tugs.

Shipments to Boston and other New England points which have been made from Port Reading during the war will be resumed on May 1 from Port Richmond, Philadelphia, as the result of an order issued by the Railroad Administration. This will result in 11 tugs and 72 large barges which were transferred to this harbor from Port Richmond during the submarine scare along the Atlantic Cost returning to their former base of operations, and is said to be one of the results of the strike in this harbor. It also means a considerable loss in the matter of tonnage handled here.

There is a heavy demand for all the domestic sizes, particularly egg and stove. Pea coal, which usually moves slowly in this market, is receiving considerable attention and there is not much surplus about. Some shippers are offering a small tonnage to slight concessions, but this is almost negligible.

The steam sizes are stronger and little is heard of quotations below full schedule prices. The better grades of buckwheat No. 1 are in good demand, and in much better shape than was the case a few weeks ago. Rice and barley are in fairly good condition considering that the mines are operating nearly full time and the warm weather is coming on.

Bids opened on Apr. 15 for furnishing and delivering one of the City Departments with 150 gross tons of stove coal showed prices ranging from $10.97 to $11.98 per ton, while offers for furnishing and delivering 1790 gross tons of buckwheat No. 1 showed prices ranging from $6.39 to $8, according to place of delivery.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	5.85	7.70
Stove	6.10	7.95
Chestnut	6.20	8.05
Pea	4.80	6.55
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—There is a better feeling in the local bituminous trade. Local deliveries are being made more promptly and prices are, in many individual instances, a trifle stronger than they were last week, although the general range remains about as they were a week back.

The high-grade coals are in heavier demand and to a greater extent than heretofore consumers are looking for quality, realizing that though the first cost might be more they are saving money in the long run. This condition is evident probably to a greater degree in New England than here, but dealers look for an increased demand for the better coals from local dealers as the season advances and they become better supplied. However, the fair grades are in good demand with prices steady.

There was good movement here during the latter part of the week, even though the boatmen had the harbor pretty well tied up. Private boat owners were able to operate, according to their own statements, 25 per cent. of their bottoms and consumers were in the main taken care of to the extent of their immediate needs. Loaded boats were eagerly picked up and brought good prices. There were many empty bottoms anchored near the docks, and when the strike was declared at an end everybody endeavored to push his boat in first.

Embargoes were placed on various shippers at the lower docks but these were lifted as rapidly as the coal was moved.

Proposals asked for by a city department for furnishing and delivering 5020 gross tons of run-of-mine brought offers ranging from $5.80 to $7.07 per ton, depending on the place of delivery.

The line trade is active and many consumers have taken advantage of local conditions to ask for larger and more prompt shipments and is storing coal. Prices for all rail deliveries are reported by some salesmen to be stronger than on the tidewater basis.

Shipping has been taking considerable coal recently, there having been a large increase in the number of vessels coming to and leaving this port.

Quotations for coal for spot delivery or on contract range as follows.

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.80 to 3.10	2.95 to 3.25
Clearfield County (good grades)	2.65 to 2.95	2.80 to 2.95
Reynoldsville	2.65 to 2.85	2.85 to 2.95
Quemahoning	2.75 to 2.95	2.95 to 3.10
Somerset County (best grades)	2.75 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.25 to 2.50	2.50 to 2.75
Western Maryland	2.25 to 2.75	2.50 to 2.75
Fairmont	2.10 to 2.35	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.35 to 2.40	2.35 to 2.60
Westmoreland ¾-in.	2.60 to 2.75	2.65 to 2.75
Westmoreland run-of-mine	2.40 to 2.65	2.40 to 2.65

PHILADELPHIA

Anthracite business good. Shippers booked full for April, except on pea and smaller. Future prospects good. "Buy early" advertising campaign started. Holidays cut production at mines. Pea causing trouble, also steam sizes. Broken very free. Bituminous unsatisfactory. Excess coal in market. Prices fluctuate. Railroad price situation annoying. Mines on short time.

Anthracite—Such strides were made in booking business during the past week that all shippers supplying good grades of coal were practically sold up, at least for April, on egg, stove and chestnut. Most salesmen have been instructed to slow up in taking orders for prepared sizes and to devote their attention to pea and the smaller sizes. Cold and rainy weather made the dealers again divert their attention from filling cellars next winter to hurry calls for a ton or two for immediate use.

Many small dealers soon found their yards empty, as they had been slow buying, and coal is not being received in the substantial quantities now demanded. In fact a number of the larger buyers are now dangerously low on certain sizes, particularly stove coal. Due to their slow ordering it is hardly likely that the dealers will receive anywhere near the amount of coal they have ordered for this month's shipment, and already the cry is heard from some of them that the companies are holding back in order to reap the benefit of the 10c. advance.

From the shippers' standpoint the outlook for the remainder of the year is far more encouraging than at any time since the middle of April. Already many companies report that they have almost enough orders for the prepared sizes to keep them busy during the month of May. The retailers are busy, of course, but there is not the rush of the past few years. Their large orders are coming in steadily but slowly and some of them seem booked for weeks to come. They too are growing most optimistic and have faith in the future. There is little doubt now that they will be busy for at least two more months.

While the market for the larger sizes is in such good condition the operators have not ceased to worry about pea and the steam sizes. The smaller operators without storage room are undoubtedly cutting the price on pea coal. Contracts are being taken at $4.50 for the season, but this is probably exceptional. For occasional cars less than this has been taken, these no doubt being instances where demurrage had accumulated, the coal being disposed of to prevent further loss. The dealers continue to have fair stocks of this size, and those who are buying are only doing so to meet the current demand. They are fully aware of the situation as to this size and freely predict that they will get the coal much cheaper when summer comes.

The big companies are undoubtedly holding firmly to the circular of $4.80, and, while they report increased sales, they continue to store heavy tonnages. Buckwheat too is giving all hands much concern, and it is being offered around $3 by some smaller houses, while the companies are insisting on the $3.40 price on the larger contracts. Many of the latter still remain unclosed, however. Rice has been sold around $2.25, which is the company-circular price for barley. One house reports the latter selling at "any old price." The big companies also say that they have much broken coal for sale and while this size is practically only made as called for, it is one of the most profitable sizes, and they are always anxious to make sales of heavy tonnages.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	5.85	7.70	Rice	2.75	3.65
Stove	6.10	7.95	Boiler	2.50	3.50
Nut	6.20	8.05	Barley	2.25	3.15
Pea	4.80	6.40			

Bituminous—Trade conditions are not at all satisfactory, as lately far more coal has come on the market than could be disposed of readily. Much of this arrived at this market because of the labor troubles on the docks at New York, making it almost impossible to ship coal in that direction via the usual routes. Strong efforts have been made to dispose of some of the tonnage locally, but with little success. Good coals were in fair demand, but the ordinary grades gave the shippers much trouble.

Consumers have not let up in their inquiries for contract prices, but seem to be more after information than anything else. They are in position to drift along with the stocks they have on hand, with the hope that they can strike a lower figure before making a contract commitment for their future needs.

The difficulty over railroad fuel seems to be as far from settlement as ever. Recently there were intimations that the railroads were prepared to ask for bids on a new basis, only to have the instructions cancelled afterward. While the companies have been depending on their stocks for most of their fuel, they have lately begun to take fair tonnages from the shippers. These are being purchased on the basis of a readjustment of price after the present controversy has been adjusted. Not many shippers are anxious for the business under such conditions and they are inclined to be quite critical of the persons responsible for the situation.

It is difficult to give a schedule of prices that would be fairly representative, as the fluctuations at times are quite variable. For instance, a mine may start with fair orders ahead and thinking that other new business might spring up will turn out an excess of tonnage, and, the demand not materializing, will be compelled to market at a loss. However, the following list gives an intelligent and fair estimate of the price situation:

Georges Creek Big Vein	$3.00 @ $3.10
South Fork Miller Vein	2.90 @ 3.05
Clearfield (ordinary)	2.70 @ 2.90
Somerset (ordinary)	2.55 @ 2.75
Fairmont lump (ordinary)	2.35 @ 2.50
Fairmont mine-run	2.25 @ 2.35
Fairmont slack	2.15 @ 2.25

BALTIMORE

Better times in coal trade are indicated despite present light demand and unsatisfactory spot prices. Exports increase and inquiries growing. Hard coal men busy.

Bituminous—The soft-coal handlers here are full of confidence as to the general future and are even encouraged concerning the very near future. This despite the immediate situation which is marked by a light demand and offerings on spot coals off the prices which the trade realizes must be maintained in general to uphold a profitable figure on mining. On contracts this feeling is still reflected by refusal to give quotations below the old government maximums. Contract closings continue rather sparse, and most consumers in need of immediate coal are out in the spot market. There is however a growing line of inquiry as to contracts and the trade is confident that a large number of consumers now relying on the open market will soon be seeking the cover of contracts.

The government departments are also out in this market for additional supplies, the Proving Ground at Aberdeen, Md., and the Edgewood Arsenal wanting jointly some 42,000 tons of bituminous, and the Fort McHenry Army Hospital at Baltimore seeking about 48,000 tons. For some time past the trade here has been relying on a pick-up in the export business to absorb some of the oversupply of coal in the domestic market, and with the arrival of a number of bottoms for that trade during the last two weeks the improvement began. The first Custom House tonnage announcement made since the war at this port showed seven clearings between Apr. 8 and Apr. 12, with a total of 22,207 tons of cargo coal and 2895 tons of bunker coal. Two ships went to Brazil, two to Cuba, two to Holland and one to Peru.

Anthracite—Hard-coal men continue busy. The first heavy rush of customers to take advantage of the cut of 40c. per ton off the retail rate of last winter caught some of the coal men unprepared, and there was a shortage of certain sizes in some yards. Orders sent to mine connections quickly brought results, however, and since the first week in April the trade has been busy with deliveries. The number of incoming orders has let down for the time being, but there is already much business on the books. Possibly a larger proportion of the business than for years is on a cash basis, to take advantage of the rule of 25c. a ton off for cash within 10 days of delivery of the coal.

Lake Markets

PITTSBURGH

Chief favorable feature is that time is passing. Prices and operating rate practically unchanged.

The coal market of the Pittsburgh district has experienced no improvement in the past week, but operators receive some encouragement from the fact that at any rate time is passing, and the passage of time involves the further reduction of stock piles as well as the nearer approach of the period of heavy lake coal shipments. Lake coal has been going forward in an extremely limited way for three or four weeks past, while the really heavy movement is not expected until summer.

Coal prices are being as well maintained as formerly. That there is a considerable measure of strength in the foundation of the market is shown by the refusal of operators to make contracts at prices as low as are often accepted for prompt deliveries. On contracts $2.35 is but little departed from in the case of steam coal, while in gas coal that figure is well maintained. By-product coal has not developed an active trading market for any proportions, and nominally it is held at $2.35 for either prompt or contract deliveries but if any important contracts were to be placed by-product coal would probably develop a market level at materially less than gas coal.

Prospects of demand are no brighter. Domestic coal shows no prospect of improvement, while as to the steel industry, it is operating at a lower rate each week and shows no disposition to make lower prices for the purpose of stimulating demand. Leading steel producers do not seem to think the time is ripe for increasing sales by reducing prices, and will probably maintain the present prices until June.

The market is as follows: By-product coal, largely nominal, mine-run, $2.35; high grade gas coal, $2.10@2.20; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.70; steam coal, slack, $1.90@2.00; mine-run, $2.00@2.35, all per net ton at mine, Pittsburgh district.

BUFFALO

Bituminous not improving. Lake trade depresses slack prices. Some big mines closing. Car shortage showing. Predictions of better business by August. Anthracite more active. Lake trade opening.

Bituminous—The demand for steam coal does not improve. Consumers seem bound to use up their supplies before they buy again, though jobbers are advising them of the risk of holding off, because a possible car shortage or a sudden rush to buy when the stocks are gone may at any time cause a bad panic. Such a state of things now appears on the face improbable, but a general return of business activity would surely cut down the car supply, and then the market would stiffen.

Some shortage of cars is already reported, mostly caused by the ordering of steel hoppers into the steel trade and by the increased movement to the lakes. The main demand along the lakes being for the three-quarter lump, the mines are making a large quantity of slack and are anxious, of course, to dispose of it. This is making the market for slack extremely limp. The Canadian trade is quiet, but if the Dominion government takes care of the bituminous coal that was purchased by anthracite retailers as a substitute for that fuel—and that is what was promised—then the trade in bituminous should improve.

The price of bituminous sizes holds well, but slack is off, quotations being $4.65 for Allegheny Valley, all except slack; $4.45 for Pittsburgh and No. 8 lump, $4.20 for mine-run from the same bed, and $3.80 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The situation does not change much. Shippers find the demand so good on all-rail routes that they are obliged to cut out most of their loading to the lakes. Some of them have been a week putting in their latest cargoes and none of them is as active as they usually are at the opening of navigation. So far about 50 cargoes have been loaded, and several coal-laden steamers have sailed, but the movement is small yet, on account of the lack of down freights. Some grain is offering and possibly the season will be in full activity before the fleet is ready to return. The clearances show seven cargoes, aggregating 63,760 net tons, all for head-of-the-lakes ports.

The local price of anthracite remains as follows to the end of April:

	F.o.b. Cars, Gross Ton	At Curb, Net Ton
Grate	$8.55	$10.25
Egg	8.45	10.20
Stove	8.70	10.10
Chestnut	8.70	10.50
Pea	7.00	9.05
Buckwheat	5.70	7.75

With 25c. additional for loading to lake vessels.

CLEVELAND

Opening of the lake season has transformed conditions in the No. 8 district so that some mines now are reporting a labor shortage. The demand for lake coal is the heaviest in years for this season of the year with the possible exception of 1918. Steam-coal consumption in Northern Ohio now is at a new low mark, with buying in proportion.

Bituminous—Operations in the iron and steel industry in Northern Ohio—the largest single user of coal in that district—now are as light as in 1914, just before the war, and in some cases lighter. This condition naturally is reflected in the coal market. Even though stockpiles are nearing the point where it will be dangerous to defer buying much longer, industrials will not even discuss purchasing or prices, and it is doubtful if a 25c. cut under present prices would move much coal.

Yet in the face of this seeming discouraging situation, operators here are more cheerful than in weeks. Upper lake dock interests are hard after No. 8, ¾-in. lump, and some operators have covered for a large percentage of their summer's output. No. 8 operators have "sold" upper lake dock men on the proposition that later on coal is going to be scarce, and that it will be the part of wisdom to crowd all bituminous possible up the lake early in the season.

Labor is getting more and more restless in southern and eastern Ohio. With prospects of wage discussions coming soon, operators appear determined to get out as large a tonnage as possible this spring. Some of the larger retail dealers are reported to be buying heavily, feeling confident prices will go no lower. They are buying high-grade coal at $2.15 and $2.20, compared with $2.60 under Government regulation. These prices so far have not proved tempting to steam-coal users, but resumption of business will see a rush to cover, and the forecast is that sometime over night prices will advance beyond expectation.

Quite an appetite for both anthracite and Pocahontas is being evidenced. The buying movement has not been passed along to consumers so far. Anthracite prices, of course, advance beginning May 1, and every retailer is certain his supplies of Pocahontas will cost him more in the fall.

Lake Trade—Though it was generally expected that 50c. to Milwaukee and other Lake Michigan ports, and 42½c. to Duluth and Superior, would be the lake coal freight rates this season, instead of 55 and 48, respectively, for last season, the rate matter has been entirely opened by the Railroad Administration. This awakened operators to the realization that Government control has not been shaken off altogether.

Cleveland coal prices, per net ton delivered, are:

Anthracite:	
Egg	$10.85 @ 10.95
Chestnut	11.00 @ 11.15
Grate	10.90 @ 11.05
Stove	10.90 @ 11.05
Pocahontas:	
Lump	7.50
Mine-run	7.20
Domestic Bituminous:	
West Virginia splint	7.05 @ 7.15
No. 8 Pittsburgh	6.10 @ 6.25
Massillon lump	6.90 @ 7.05
Steam coal:	
No. 6 slack	4.40 @ 4.50
No. 8 slack	4.70 @ 4.85
Youghiogheny	4.90 @ 5.05
No. 8, ¾-in.	5.35 @ 5.50
No. 6 mine-run	4.40 @ 4.50
No. 8 mine-run	4.70 @ 4.85

DETROIT

Sales of bituminous coal are few in both the steam and domestic branches of the trade.

Bituminous—Should the stagnation of the Detroit market continue, developments troublesome for buyers are quite likely to occur according to the expressed judgment of Detroit wholesalers. The prediction is made that buyers, who, for one reason or another are holding back, will all be coming into the market together in the late summer or early fall, and the result will be a shortage in supply.

Neither the users of steam coal nor the retail dealers appear to be developing a receptive attitude toward buying. Jobbers say orders are few and come irregularly and, in most instances, are of small size. They declare that business could scarcely be more unsatisfactory. Some of the retailers are taking domestic lump in one or two car lots, conditional on immediate shipment, to enable them to get the coal to customers before domestic buying ceases.

The unwillingness of buyers to release orders is attributed by the jobbers to the large supplies of bituminous that are still to be found in the yards of steam plants and retailers.

The steam-coal users, in some instances, are said to be waiting because of a feeling of uncertainty concerning the stability of prices, though a larger proportion of them is delaying buying to afford opportunity for clearing their yards of stock which they do not desire to mix with the better grades of steam coal now obtainable from their normal sources of supply. The retailers are reluctant to add to their already large stocks of bituminous, as in doing so more of their working capital would be tied up for several months.

Interest in contracts is lacking. Prices quoted in connection with the few inquiries received are said to be those fixed by the fuel administration. On day-to-day business, however, small sizes are offered at a lower basis. The reduction on slack is reported as much as $1 a ton below the Government price. The latter is generally maintained on lump and prepared sizes.

Anthracite—Domestic consumers are not displaying much alacrity in stocking up with anthracite for next winter's needs. Despite the impending advance in price, only a few of the householders are buying now. The supply in the hands of dealers is adequate.

COLUMBUS

A turn for the better is shown in the Ohio coal trade. Demand is improving and a better tone is exhibited. The screenings situation is not so bad as formerly, owing to a reduction in lump production and a better demand for the small sizes. Prices are still uncertain.

The Ohio coal trade shows a distinct improvement from the previous week, and consequently more optimism is in evidence on all sides. There is a good demand for the fancy grades such as Pocahontas and splints, and many operators have their output sold for a month ahead. The railroad fuel situation is still hanging fire.

Bids to supply fuel for the month of April were opened recently by quite a few railroads in this territory. No announcement has yet been made as to tonnage awarded and prices. Some low prices were quoted, but generally speaking the larger concerns upheld quotations. When the railroad fuel question is adjusted it is believed the entire trade will be stabilized. Iron and steel plants are increasing their requisitions slightly and general manufacturing appears to be improving.

The domestic trade is quiet, as is usual at this time of the year. Retailers are only doing a small business and their stocks are generally sufficient for the present. Dealers are buying the better grades quite actively. Retail prices are being shaded to a certain extent but not sufficient to demoralize the market. Many dealers believe that there will be a strong demand early in the stocking season and are making preparations accordingly.

The lake trade is slow in opening, as was predicted. Officially, navigation opens May 1, but some cargoes have been loaded. Shippers are not making large lake contracts as the price question is still unsettled. Shippers who control docks in the upper lake region will start soon, but the main bulk will not be moving until after June 1.

CINCINNATI

General market conditions satisfactory, though no great demand is yet in evidence.

Conditions in the Cincinnati district remain about as they have been for the past several weeks, with only a comparatively light demand, although in some instances dealers are reporting slight indications that the situation will improve in the near future. The renewal of contracts for steam grades, which has occupied the attention of the trade for some time past, has shown a tendency to fall off to a certain extent, undoubtedly due to the uncertain conditions prevailing in some of the industrial lines.

While industrial conditions in this district are generally reported as fair, few, if any, of the factories are working up to their full capacity, while some of them have appreciably slackened. This condition naturally has its depressing effect on the demand for fuel. It is the consensus of opinion among business men generally that with the signing of the peace pact confidence will be restored and business will gradually adjust itself to more nearly normal volume, while some few predict a real boom stage when the retarding influences are removed. The local trade is confidently looking forward to the future, but in the meantime would appreciate any influence which would effect an immediate improvement.

Contrary to the general expectations the dealers supplying the domestic trade find themselves confronted with a slight, though very satisfactory increase in demand. It was the opinion of most of them that as a result of the mild weather during practically the whole winter, and the fact that the people had prepared for an entirely different brand of weather by laying in a large supply of coal last summer and fall, the demand would show a large decrease. However, they are pleased to find themselves mistaken. Altogether, the present state of the market may be described as satisfactory, all things considered.

LOUISVILLE

Eastern Kentucky operators increasing production and meeting with good demand. Western Kentucky trade finding things dull, due to close differential in prices as between grades.

Eastern Kentucky operations are now up to a 65 to 70 per cent. full-time basis, there being an active demand for steam coal as well as a fair demand for domestic grades. The better grades are getting the call, and the operators in that section are feeling optimistic. The demand for steam coal is picking up steadily, both mine-run and nut and slack showing movements. Domestic demand is not so strong as it was, but many retailers are beginning to buy and stock some coal.

In Western Kentucky the mines are doing a little less than 40 per cent. as a whole, due to there being little demand for lower grades when the market is fully supplied with the better eastern Kentucky stocks. Operators from the western section of the state are feeling a bit optimistic just now, especially in connection with the outlook for block coal. However, a fair volume of nut and slack as well as mine-run is moving.

Prices are being well maintained throughout the fields, there being little quoting except for April, May and June delivery on domestic coal. Several good railroad contracts for engine coal are about to be closed, and prospects are generally good in connection with the lake outlook.

Eastern Kentucky is quoting block at $2.85 to $3; Jellico grade, $3.25; egg, $2.75; mine-run, $2.40; nut and slack, $2; Western Kentucky is quoting block and egg, $2.60; mine-run, $2.35; nut and slack, $2.05.

BIRMINGHAM

Domestic coal moving well but steam demand slack. Prices remain firm. Mines operating on three- and four-day schedules, but a better average daily output is being obtained.

Coal men report a sustained demand for all grades of good domestic coal, the supply of which is short even at this early season, and the lower grades of domestic fuel are now being taken by dealers, who are beginning to show some accumulation of stocks in their yards. Domestic mines are running full time, though the output is not up to normal. Prices are as follows per net ton at mines for lump and nut:

Carbon Hill	$3.15
Corona	3.40
Big Seam	2.90
Black Creek and Cahaba	3.85@4.50
Montevallo	5.00

There has been no noticeable improvement in the steam situation, those consumers who do have contracts in force buying as their needs materialize. Sales are confined to small lots and few contracts are being made. Sales agents and jobbers, however, are in no wise pessimistic and are confident that a good market will develop as soon as industrial conditions become more settled. Government prices in effect Jan. 31 still obtain for steam coal.

Coke

CONNELLSVILLE

Market continues to decline. No sale for byproduct coal. Heavy restriction in Connellsville coke output.

The Connellsville coke market has continued to exhibit a declining tendency, prices being a shade lower both on spot lots and on deliveries to the end of the month, while it develops that more contracts were settled at $4 and fewer at $4.25, for April deliveries, than was originally reported.

How much liquidation in production costs there has been cannot be estimated. It is known that there is considerably more efficiency, and it is rumored that wage reductions at small operations have been fairly

numerous. The large operators have not made any reductions whatever. While coke is now available at prices considerably below what was recently claimed to be the cost of production, it does not follow that actual losses are being experienced, since the cost computation was based on coal at the market price, and that market price would represent a profit, the difficulty being that coal cannot be sold in any tonnage at the market.

The Connellsville coke industry has had to stand the brunt of the reduction in blast-furnace operations, by reason of there being so many steel interests that use both byproduct and beehive coke when they are running full, but when blowing out furnaces shut off the beehive coke before they touch their byproduct operations. On the other hand the Connellsville operators are not experiencing any competition in the market from byproduct ovens, coke supply being too limited to enable the byproduct ovens attached to blast furnaces to attempt to dispose of surplus coke to other furnaces. The result of the decreased coke consumption falling particularly upon the Connellsville region is that production is now running not over 150,000 tons a week, whereas in July, August and September, before the influenza epidemic affected production, the weekly output ranged from 325,000 to 350,000 tons, so that there has been a decrease of about 55 per cent.

Odd lots of furnace coke have been available at $3.60, and this price has also been quoted on deliveries to the end of the month. There is a rumor current that the remarkable price of $3.30 has been reached, and this may be correct if it involved coke of such character that it could be used by very few furnaces. April settlements appear to have been chiefly at $4, with a few at $4.25. Deliveries continue, in a limited way, on contracts that were written at "last Government price" but voluntarily reduced to $5. Foundry coke remains at $4.50@6.00, depending on brand, with fairly good demand in small lots. All prices are per net ton at ovens

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Apr. 12 at 150,415 tons, a decrease of 21,935 tons.

Buffalo—The trade is decidedly quiet and will remain so till the iron trade is more settled, for then the ore contracts and charters for distributing the Lake Superior output will be made and the regular season will open. As yet nothing in that line has been done and all vessels that have gone after ore will merely carry some that was left over last fall or on long-term contracts that they may have. The price of coke, f.o.b. here is $7.25 for 72-hour foundry, $6.60 for 48-hour furnace and $6.10 for off grades. Breeze and other fuel cokes are practicably unsalable.

Middle Western

GENERAL REVIEW

More sales being reported, opinion being strong that market will show steady improvement from now on. Prices holding up. Domestic demand inactive.

There has been little change in the Mid-West market during the past week. However, what difference exists is for the better. Operators and jobbers alike are reporting more sales, and at reasonable prices. There is a prevailing opinion that from now on the market will improve slowly but steadily. Practically all of the large operators in this district received bids calling for their best contract propositions to supply coal to the various army camps and stations in this territory. Careful investigation shows that nearly all the operators making bids for this business have kept strictly to the late Government prices. A number of operators decided not to make any bids for the business, on account of the red tape involved in the making of a contract with the Government. Some also said that contracts with the Government are entirely too one-sided, favoring, of course, the Government.

Prices are holding up fairly well. While there has been but little demand for Franklin County screenings, we understand the prices on this grade of coal have been maintained steadily, and without deviation. Other southern Illinois coals, especially from the Belleville district, have been selling at cut prices. This is also true of coal from the northern districts of the state, and the Springfield district, considering the Springfield region as a whole, has maintained the price on its product remarkably well. The high-grade producing districts in Indiana continue to adhere strictly to list prices and report considerable business received on this basis.

The domestic situation in this territory, and especially in northern Illinois, is inactive. This is because practically all householders have some coal in their bins. Those who ran out of coal purchased late in March, or before, and as a result are no longer in the market. Dealers report that their trade show practically no inclination toward stocking coal. This means, of course, that there will be a congestion later in the season.

CHICAGO

Much "distress" coal dumped here. Good demand for Pocahontas. Why public is paying high prices for coal.

The Chicago steam market is not improving so fast as had been hoped, and Chicago continues to be a dumping ground for "distress" coal. The domestic situation is quiet in the extreme. There is a good demand for Pocahontas, and we understand that the price on this coal is holding firm at $3.50 to $3.75 for lump. There is a prevailing opinion among the retailers that when this country begins to export coal but little Pocahontas will reach this market.

Mr. Upham, the president of the Consumers Co., issued a statement to the public wherein he claimed that the high prices for coal are entirely on account of Government supervision. He says that the retailers are not the coal profiteers, but that the United States is to blame for the high prices. To give an idea of his argument, we quote the following paragraph:

"Take bituminous coal, an Illinois product. Price fixed by the Government at $2.50 per ton at mines. The freight rate, which was 90c. per ton, is now $1.55, plus a 5c. war tax, which brings the retail price up to $4.10 per ton, more than the retail price before the war. Teaming was then 70c. per ton, and is now $1 per ton. We allow 85c. for shortage, yardage and profit, and pay the $1 teaming charge to the men. That brings the price of Illinois coal up to $6 per ton."

MILWAUKEE

Prospect of higher prices for anthracite serves to stimulate the demand. Early agitation in favor of the establishment of municipal coal yards.

Newspaper gossip, suggesting a possible advance of $1.50 per ton on anthracite over present prices, has had the effect of stimulating business to some extent. Dealers report a tendency on the part of domestic consumers to put in supplies for next winter, with the result that deliveries are more active than for some time past. Other conditions remain the same. There is plenty of coal on hand, and cargoes will be reaching the docks from the lower lakes in the course of a few days, but there is no sign of price shading even on the commonest bituminous grades. The prospect that coal will be no cheaper, with the strain of war's needs removed, naturally causes dissatisfied comment, and public agitation of the matter may be expected. Mayor D. W. Hoan is in the field early with an argument in favor of the establishment of municipal coal yards, not only in Milwaukee, but at interior points.

ST. LOUIS

An easy, quiet and unattractive market, with plenty of coal and no orders. Steam and domestic city and country business quiet.

Local conditions are extremely easy. The weather is mild and there is but little demand for domestic fuel. Such orders as come in are for small amounts only and for the cheaper grades. A few orders have been placed for storage coal for household use, but these are scattered. The wagon-load steam business is easy on account of the slowing up in activity on the part of manufacturing plants.

The country demand for all kinds of coal is practically off, except on nut for range purposes in the smaller places. There is some call for anthracite chestnut, but other than that there is little coal moving.

In the Standard district business is at a standstill. The trouble right now is to move lump and egg. Nut and screenings are in fairly good demand, but even at that the operators do not seem to realize that they can get the cost of production, and lower prices still prevail.

In the Mt. Olive field conditions are tranquil. Mines are working a couple of days a week, as in the Standard field. The coal here is moving to the north. There is little coming in locally. There is a little railroad coal moving, but it is light, and there is some question as to the price.

In the Carterville field of Williamson and Franklin Counties, as well as in the Du Quoin field, things are moving along slowly but apparently satisfactorily to both miner and operator. Some mines manage to get a couple of days a week, and some of them do better than that; others have been shut down for some time, and a number are expecting to shut down to make necessary repairs.

No Arkansas coal is coming in, and judging from the attitude of the dealers little will come in, even if the mine troubles in that state were settled. There is no demand for smokeless, although none is offered for this market.

The present prevailing circular per net ton f.o.b. mines is:

Williamson and Franklin County Association:		Mt. Olive and Staunton		Standard	
Lump, egg and nut	$2.75	....		....	
Washed Nos. 1 and 2 nut	2.85	....		....	
Independent:					
Lump, egg and nut	2.55	2.55	Lump and egg	2.25	
Washed Nos. 1 and 2 nut	2.85	....	2x3 nut	2.00	
Mine-run	2.35	2.20		2.00	
Screenings	2.20	2.05		1.75	
3-in. lump	....	2.30		....	
2-in. lump	....	....		2.15	
2x6 egg	....	....		2.10	

Williamson-Franklin rate to St. Louis is $1.07½; other rates $0.92½.

COAL AGE

Volume 15 New York, May 1, 1919 Number 18

All Price Revisions Will Be Upward

By R. Dawson Hall

BACK in 1900 there was an owner of a large lumber tract who said he wouldn't cut his timber so long as wages stayed so high. He could remember when men earned only 50c. a day and board, and he would "like to see the workingman who could earn legitimately more than a dollar a day." He's dead now, and the timber has been cut by more aggressive men. They made a big profit on the job despite the high wages, because prices were high as well as wages.

In considering whether wages are high or low it doesn't do to look back to Buchanan's day. We have had a Civil War since he was President. Nor should we worry about prices in 1913; there has been an even greater war since then. Prices are higher and wages are higher, but there is no need for bewilderment. All we have to do is to learn the value of the new dollar. We have in the readjustment period to readjust our thoughts and conceptions to a new sixty-cent standard. It is just as much a depreciated dollar as if some monarch had clipped away 40 per cent. of its substance after the manner of merry monarchs a few centuries ago.

"Prices and wages have gone up, and what goes up must again come down," people very simply but not very profoundly remark. As a boy we learned that the ball that went up sometimes stayed up and never came down. So the ball of prices beaten by the battledore of war has fallen on the roof of increased currency and lodged in the eaves trough of high wages. It can't be reached or brought down.

The war has lifted the cost of production and the selling price, but it not only caused these prices and wages, it also created conditions that will keep them fast—it built the unions which will not allow wages to fall; and it created a large volume of unnecessary currency that cannot be withdrawn or absorbed for years, if indeed it can ever be. The large quantities of this currency, like too many men on a job, get in their own way so that each "iron man" does less than a man's work.

Every one wants prosperity; we all know it cannot come without popular certainty that prices will go up, or at least sail along unchanged. Those, therefore, who are convinced that prices are, in the main at least, as low as they will ever be, should call meetings to convince the public of that fact. The principal need of the industry, of mine owner, manager and miner is prosperous business, everyday operation. Go to it now! Let every man know that you are confident that there will be no further wage or price clipping, but that if any change occurs it will be a higher wage or price, especially in those industries that have not shared hitherto in the prosperity arising from the war. Don't be a trailer, be a motor and pull. Establish your business, even if in doing so you help your neighbor as much as you do yourself.

IDEAS AND SUGGESTIONS

To Save Time in Laying Out Mine Curves

By R. Dawson Hall

In the United States, railroad curves are calculated in a manner that makes it possible to have simple angles of deflection for 100-ft. chords. The American method of laying out a curve is much simpler than the English method, because the angles of deflection can be added mentally. The method of describing the curve is easily understood and is just as expressive as the English method of stating the radius.

When running mine curves the engineer usually falls back on the English method, using a definite radius of so many feet or tens of feet, letting the deflection angle be what it may. He does this because he thinks he cannot use the regular deflection table, as it is calculated for the 100-ft. chord, which cannot be used where the radius runs between 20 ft. and 200 ft. The chord would in many cases be longer than the diameter.

To make the procedure still in general use plain it may be said that it is usual to take the formula:

$$\frac{\frac{1}{2}\ chord}{radius} = sin\ \frac{1}{2}\ deflection\ angle$$

and assume the exact chord and the exact radius desired and calculate the deflection angle. This is all very well, but it is not advisable to accept that angle when it is found. It may run 9 deg. 45.3762 min., and if there are many chords to run the addition of them would make one dizzy. The better way is to say the deflection angle should be 10 deg., not 9 deg. 45.3762 min., and then take the table which the transitman will find in Searles, Trautwine, Nagle or other fieldbooks, and from that table make his calculations, remembering that the radius of a circle having any given deflection angle per chord is proportional to the length of the chord.

The same is true of the middle ordinates and tangential offsets. Let me compare the radii, midordinates and offsets for a 6-deg. standard curve laid off with 100-ft. chords and a 6-deg. miniature curve laid off with 10-ft., 20-ft. and 20-m. chords respectively:

Chord	Degree of Curve	Radius	Middle Ordinate	Tangential Offset
100 ft.	6	955.37 ft.	1.31 ft.	5.234 ft.
10 ft.	6	95.54 ft.	0.13 ft.	0.52 ft.
20 ft.	6	191.07 ft.	0.26 ft.	1.05 ft.
20 m.	6	191.07 m.	0.26 m.	1.05 m.

It will be seen that when the chord is one-tenth as long as is the chord on which the table is based the radius, the midordinate and the tangential offset are each one-tenth as long. The standard table is almost as readily used as if it were calculated for the laying out of a miniature curve.

As a 20-ft. chord makes a convenient length for mine work Frederick MacCoy, a mining engineer of Jerome, Ariz., has calculated a table for laying out curves which appeared in the *Engineering and Mining Journal*. It is a compromise between the English and American systems. The radius has been assumed to be as in the second column, and the deflection angle corresponding to that radius has been calculated. All the fractions of minutes in the deflection have been ignored or the nearest even minute has been taken and the results, thus mutilated or modified, are shown in the first column. Mr. MacCoy has recalculated the radius from the deflection in the first column and set that radius down in the third column as the "actual radius." It will be seen that it closely approximates the radius as recorded in the second column.

In laying out timbers, tipple bents and other work involving chords of unusual length, the better plan is to refer to the railroad tables, divide the figures given for the radius, midordinate and tangential offset by 100, and multiply by the chord chosen. The deflection angle, or "angle" of the curve, will then of course be based on the chord of unusual length which conditions have made necessary or desirable.

TABLE OF STANDARD CURVES FOR MINE TRAMROADS

4 46	240	240.47	381063	7.15
4 36	250	249.18	2.396511	6.90
4 24	260	260.50	415807	6.60
4 14	270	270.75	432569	6.35
4 06	280	279.55	446461	6.15
3 56	290	291.39	464477	5.90
3 48	300	301.61	479449	5.70

Note: Curves of less than 100-ft. radius should be laid out by half chords.

As Mr. MacCoy points out, a similar adaptation of tables of switch curves may be made to fit any gage of track by the use of the following rules: For the same gage the radii of the turnout are to one another as the square of the number of the frog. For the same frog with different gages, the radii and frog distances are to each other as the width of gage. For a standard unit, a No. 1 frog requires a turnout radius of 2 ft. on a 1-ft. gage. The same frog on a 3-ft. gage requires a turnout radius three times as long, or 6 ft. A No. 6 frog on a 1-ft. gage needs 6 × 6 times as long a turnout radius as a No. 1 frog on a 1-ft. gage—that is, 6 × 6 × 2, or 72 ft. Changing the gage to 3 ft. the turnout radius will be three times as long, or 216 ft. Similarly a No. 6 frog with a 1-m. gage requires a turnout radius of 72 meters.

Remodeling a Poorly Designed Switchboard

By J. J. Nolan
Linton, Ind.

Figs. 1 and 2 show a side and a front view of a three-panel switchboard which was erected some few years ago by a construction company at a certain Indiana mine without taking into consideration facilities or room on the rear of the board for repairing or renewing parts, the need for which the numerous con-

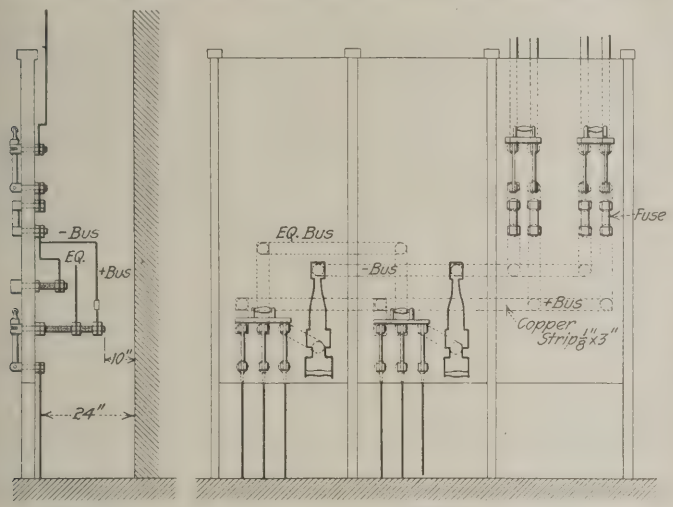

Fig. 1 Fig. 2

FIGS. 1 AND 2. SIDE AND FRONT VIEW OF THREE-PANEL BOARD

nections shown should have made evident unless all joints were designed properly and pulled up snug.

Trouble began later with hot connections in numerous places on the rear of the board. The limited room of 10 in. between the positive bus and the wall made it difficult to make permanent repairs, especially as the gas in the mine required the booster fans to be operated

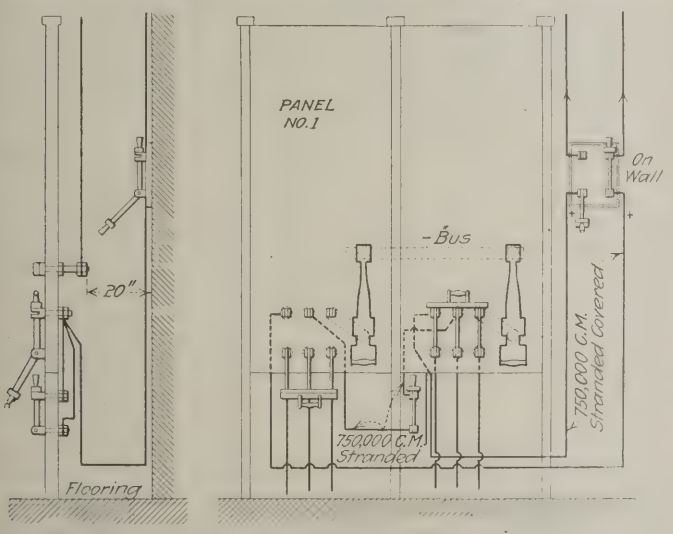

Fig. 3 Fig. 4

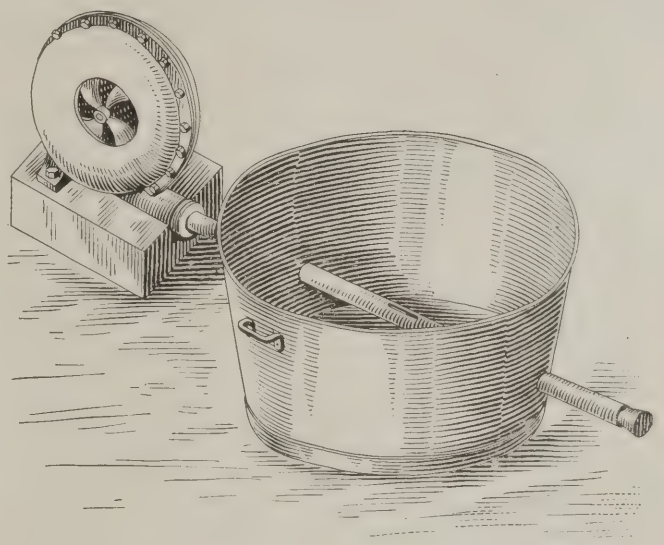
FIGS. 3 AND 4. PLAN OF BOARD AND SYSTEM OF WIRING



continuously day and night. Furthermore, as may be seen, the whole length of the three panels was charged on the rear whether one or two generators were running.

Figs. 3 and 4 show a plan of the board and wiring which I designed and later adopted to do away with one panel altogether as well as to reduce the number of connections on the rear of the board from 42 to 19. This increased the clearance between wall and bus from 10 to 20 in. and permitted the disconnection of the positive from either side as desired. The new arrangement makes for safety and allows plenty of room for the removal or repair of almost any part without entailing a shutdown.

The two single-pole knife switches on the wall and the one single-pole switch connecting the equalizers are left closed only when there is occasion to repair or remove some part of one panel. Fig. 4 shows No. 1 panel when cut out, also the equalizer and left-hand single-pole switch on the wall when repairs are to be made on this side.

A Prospector's Washtub Forge

A handy forge frame is made out of an old galvanized-iron washtub. A 2-in. pipe, with a slot $\frac{1}{4}$ x 2 in. cut in the upper side, is placed horizontally, as shown, and connected with the bellows or blower. The other end of the pipe is plugged with a piece of wood. The tub is then filled to the level of the pipe with dirt or ashes, and the rest of the way with coal. If the pipe gets stopped up, the wood plug can be drawn, and the

INGENIOUS FORGE MADE OF OLD WASHTUB

fine coke and ashes blown out. This washtub forge is much more simple for the prospector to put together than one constructed of lumber or rocks, and is fireproof. Furthermore, lumber is not always obtainable "forty miles from nowhere." The tub is wide enough to support conveniently the usual lengths of steel used in such work. If long pieces of hand steel are to be sharpened, a bent-rod support is easily attached to the tub. When the prospector moves, the tub is not necessarily an inconvenience, for it can be used as a packing case.

THE IMPERATIVE NEED for thorough lubrication and protection of wire ropes on slopes and shafts is pointed out by S. Hardesty in a paper on "Stresses in Wire Rope" in the "Proceedings" of the American Society of Mechanical Engineers. The lubricant chosen should be one which will penetrate to the inside of the rope and thoroughly saturate the hemp core. A heavy dressing which merely forms a coating on the outside of the rope may be worse than useless, for it may give a false sense of security while the inside of the rope is devoid of lubricant and possibly even rusting. If slippage of the strands and wires can take place, as in well lubricated ropes, then when a rope is bent around a sheave of proper diameter the stresses will be negligible.

Underground Coal-Loading Machinery*

By E. N. Zern
Pittsburgh, Penn.

SYNOPSIS — *Many types of coal-loading machines have been introduced in American mines. These vary from shaking chutes to elaborate and ponderous devices that both mine the coal and deposit it in a car. None has been received with universal favor, although most of the devices have achieved a fair degree of success. It is manifestly unfair to put any coal-loading machine to work unless mining, haulage and other conditions are made favorable to its operation.*

THE coal industry has ever been beset with problems, some evanescent, because the solution has been comparatively easy, and some recurring with such persistent regularity that it may be inferred they have never been solved. In this latter classification falls the labor problem, which is now doubtless the biggest problem confronting the industry.

In the past the perplexities which have arisen from an unsatisfactory labor situation have never brought disaster to the industry, but, instead, have benefited it to some degree. The labor situation, in a sense, has been responsible for almost every improvement in mining from the laying of the first pair of mine rails down to the adoption of the modern coal-cutting machine. During our seven centuries of mining experience, necessity has unfailingly mothered invention. Coal production is now but little more than a series of mechanical processes.

The mine, which we are now pleased to call modern, uses machinery to do the undercutting, electric or air-driven drills to bore the holes, explosives to bring down the coal and locomotives to haul it away. A few clever devices on the tipple or breaker assist gravity in the work of preparation. The missing link in the chain of mechanical operations is the device which will replace or simplify hand loading. The advantages of underground devices for the loading of coal may be stated as:

1. The output of coal per employee can be increased, or, in other words, fewer men will be required for a stated output. Present figures of production are so low that they should be easy of betterment.

2. The development area of the mine can be greatly reduced. With the use of machines it should be possible to get the same amount of coal from an area one-half to one-fourth as great as with present practice. The benefits to be derived from a restricted area are: (a) Less capital will be tied up; (b) ventilation will be cheapened and simplified; (c) haulage systems can be better organized—trips can be moved rapidly and with less delay; (d) trackwork, timbering, etc., being concentrated, can be done to better advantage; (e) fewer mine cars will be needed; (f) supervision will be more effective; (g) power costs will be reduced and (h) the safety of employees can be better guarded.

3. The roof can be kept in better and safer condition, owing to the rapid rate of advance of rooms and entries and the subsequent drawing of the pillars. Where combination mining and loading machines are used, the integrity of the roof is particularly well guarded, inasmuch as no explosive is employed.

4. Thin beds can be worked profitably. The number of mines now opened in seams from 3 to 5 ft. thick is surprisingly large. It is well understood that the problem of haulage and loading is particularly troublesome in low beds, and it may reasonably be expected that such mines will early embrace the help of machinery.

5. The summation of all advantages indicate that the cost of producing coal can be reduced.

The several devices here shown do not include all that have been brought forth during the past decade. Omission of several has been made necessary because they are at the present time undergoing reconstruction, and the feeling existed on the part of the maker that to show the experimental machine might prove an injustice to the future model. However, a sufficient number are here depicted to indicate the various principles underlying the construction and operation of past and present devices.

Mechanical conveyors, perhaps, should not be included as a type of coal-loading machine, inasmuch as they require that coal be shoveled into them. For the purpose of this paper, however, the term "coal-loading" is used with a liberality that will permit the inclusion of conveyors, the principle of which is found in most of the so-called "loaders."

The first coal-face conveyor used in the United States was the joint invention of Clarence Claghorn and W. C. Blackett. It was installed at Vintondale, Penn., and although it has already been described, a brief reference to it as a type will not be out of place.

The coal worked at Vintondale is the "B", or Lower Kittanning, bed, 42 in. in thickness, with a dip of 8 per cent. and an average cover of 200 ft. At one time there were two different arrangements, one using a single-conveyor system and the other using a triple conveyor.

The method of working with the single conveyor is as follows: The main entries are driven up the pitch through the center of the property and cross headings

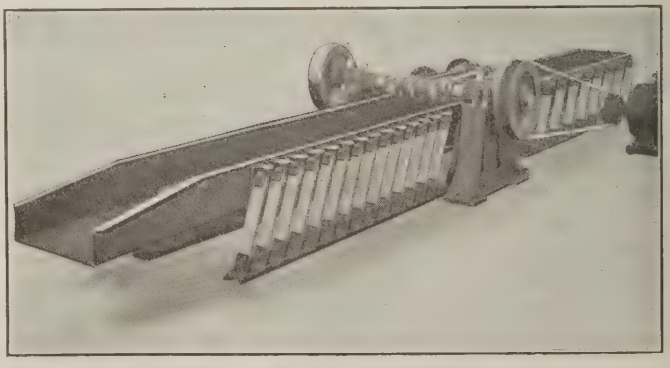


FIG. 1. BALANCED TYPE OF DODGE-ZIMMER CONVEYOR, SHOWING CHUTES AND SUPPORTS

*Abstract of paper presented before the annual meeting of the Coal Mining Institute of America, Pittsburgh, Penn., Dec. 5, 1918.

are turned from these every 400 ft. Block headings are driven perpendicularly off the cross-entries on 265-ft. centers, this allowing a solid face of 250 ft. These block headings are driven 15 ft. wide, but bottom is lifted only 7 ft. wide near the rib, and of such depth as to allow a clearance of 6 ft. from the top of rail. The length of the block heading is 350 ft., and the one nearest the outcrop is first attacked. The time required in removing equipment from one block to another is usually about 15 hours, the change, of course, being made when each block is worked out.

The conveyor consists of a trough or pan, made of sheet steel ⅛ in. thick, 12 in. wide at the bottom, 18 in. wide at the top and 6 in. high. The conveyor, which is 250 ft. in length, is made up in 6-, 12-, 15 and 18-ft. sections, connected together by means of ½-in. flat-headed bolts, countersunk. The conveyor chain is made of either steel or malleable cast iron, held together by bolts and so designed that repairs can be quickly made.

The number of men required to run a block with the single conveyor is 13, consisting of the block boss, machine runner and helper, driller (who also acts as shot-firer), engine boy, head man and six loaders. With a 5-

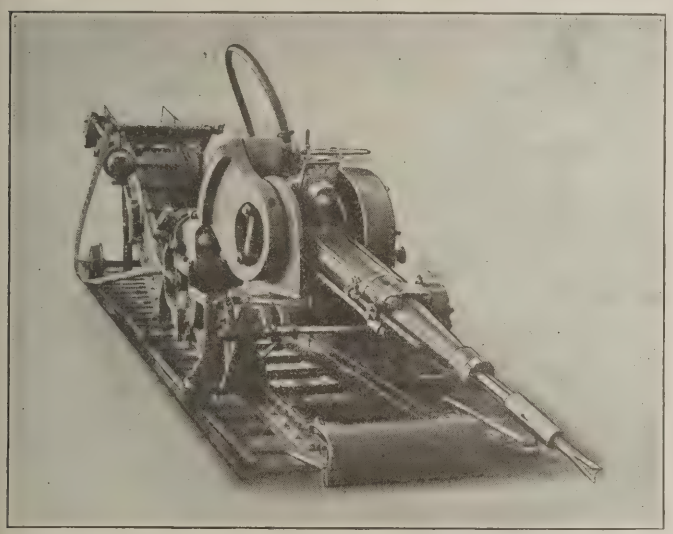

FIG. 2. INGERSOLL-RAND MACHINE READY FOR WORK

ft. undercut a block throws 125 tons of coal. Four cuts per week are, on an average, obtained from each block, making a daily average of 100 tons per conveyor.

The triple-conveyor system has been found an improvement on the single conveyor as it means less cost for development and for deadwork in mining the block. When the block is ready for operation, a conveyor 350 ft. long is placed on the block heading. Extending to either side is a conveyor 250 ft. long, with delivery ends directly over the main conveyor, one being 5 ft. in advance of the other. Each conveyor is driven by a 20-hp. motor, incased in a sheet-iron frame mounted on steel shoes, so as to be easily moved.

When a block is cleaned up, the timbermen move up the conveyor, set the break rows, pull the timber and make everything ready for the conveyor to start when the opposite block is loaded out. The main conveyor, which is made up of 12-ft. sections, is disjointed about every third day, and one of the sections taken out and moved to the block heading next to be worked.

The method of handling the cars to the conveyor is simple. A side track is laid 300 ft. long, of which the

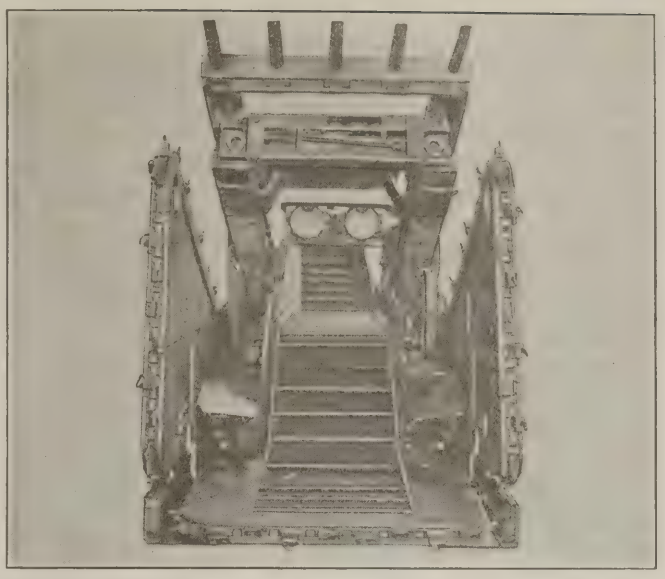

FIG. 3. FRONT VIEW OF JEFFREY-MORGAN MINING AND LOADING MACHINE

block heading is the center. Connection is made with the main track at the lower end and a crossover switch is placed directly under the conveyor. At the upper end of the siding is placed an electric hoist. A trip of 14 cars is shoved into the empty track, the rope is attached and the trip pulled up to the conveyor. As each car is loaded the trip is pulled forward. When loaded, the trip is dropped on the loaded siding, the rope disengaged and attached to the empties.

The working of the face is similar to that of the single block, and the output averages 150 tons per day. An account of this operation, given in 1907, stated that the cost averages for two years showed that block coal was loaded on the cars 35 per cent. cheaper than the district mining rate, and that this cost could be reduced when contemplated improvements were added.

Other forms of conveyors in use for transporting coal from the face to the main haulways are:

Belt Conveyors—These consist of an endless belt made of various materials and operated in the same manner as the chain-and-trough conveyor just described. In construction they are similar to the appliances used for conveying coal to bunkers in power houses or for bringing coal from a slope opening to the tipple. Where used in England[1] they are commonly built in lengths of 300 ft., although in some instances the conveyor attains a length of 600 ft. The belt usually runs at a speed of 50 ft. per minute and delivers from 20 to 25 tons per hour. The saving at one mine is reported as 10c. per ton in the cost of delivering the coal to the shaft bottom.

Shaking Conveyors—In the United States the only conveyor, I believe, which uses this principle is known as the Dodge-Zimmer conveyor and is made by the Dodge Manufacturing Co. One driving mechanism is employed, this being located either at the end or at the center of the conveyor. When located at the center it is known as the "balanced type," and when at the end as the "unbalanced type." In operation the conveyor has a short backward and forward motion, with a slight rise on the forward stroke which moves the material forward in the trough in a smoothly flowing stream and without transporting any of the mechanical parts.

[1]Sydney F. Walker, in *Coal Age*, Vol. 10, p. 744.

The conveyor consists of a steel trough of proper depth and width for the transport of the coal. This is supported by inclined laminated spring legs, and is attached to the driving mechanism by connecting-rods.

The great advantage claimed for this type of conveyor is the absence of working parts, as compared with the chain and flight type of conveyor. In operation the only part that moves on a wearing surface is the eccentric shaft in the driving mechanism; expenses of operation and maintenance are low because of the few moving parts; the power required to operate is small, a conveyor 12 in. wide and 65 ft. long conveying 7 tons of coal per hour, requiring but one brake-horsepower.

Moving Trough Conveyor—In this conveyor the trough moves along the coal face and delivers to mine cars at a central point. The movement of the working trough is accomplished by the aid of wire ropes coiled on a drum located at the central delivery point. In the Thompson apparatus there is one rope, the ends of which are secured to the ends of the moving trough, the middle of the rope being carried around friction drums or pulleys. The trough itself is moved from end to end of the face by a motion of the rope over the friction drum. The action is similar to that of an endless rope except that the trough is looped into the rope. In the Bridgewater conveyor the main-and-tail rope system is employed.

Any type of conveyor, so arranged as to be parallel with the face and advancing with it, offers the following advantages: It can be made low, some conveyors being only 6 in. above the floor; the distance through which the coal must be raised by the loader is small, hence he can load more coal with less muscular effort; it is unnecessary to rip the roof or take up bottom; it requires no track from the haulways to the face; coal can be shoveled with less fatigue since the conveyor is right at the loader's back; the conveyor can be readily worked in various lengths and made to follow the face throughout the working of the panel; it requires little power to operate, varying from 5 to 10 hp.; it increases the tonnage output per employee at a decreased cost.

Combination Mining and Loading Machines

The combination in one machine of a coal-cutting unit and a coal-loading unit represents an ideal, long in the minds of inventors. Such a machine combines the functions of the coal cutter, the auger for boring holes, the shotfirer, the explosive and the hand loader. In scope, then, the adoption of this principle to the winning of coal is about the biggest thing that has ever been projected in the history of the art. The displacement of explosives is one of the strong points in favor of this type, and when first brought out the statement that it eliminated explosives attracted attention.

The Ingersoll-Rand cutter and loader will be readily understood by all mining men as its main parts consist of a powerful air-driven puncher, mounted on a carriage over a conveyor. A lever is used to elevate or depress the puncher pick, a second lever moves it from rib to rib through the agency of a small air engine, while a third lever moves the whole puncher, together with its truck, bodily toward or away from the face, the conveyor remaining stationary within certain limits, or accompanying the forward or backward motion of the puncher, as desired.

The puncher itself makes about 160 strokes per minute and is controlled in the same manner as the ordinary hand-operated machine, going from rib to rib and making a cut extending the entire width of the entry. The conveyor is driven by a separate engine suitably controlled by a stop valve. The mine car is filled evenly by moving it about three times during the loading process.

Making the undercut is the longest part of the operation, requiring from 25 to 40 min., according to the

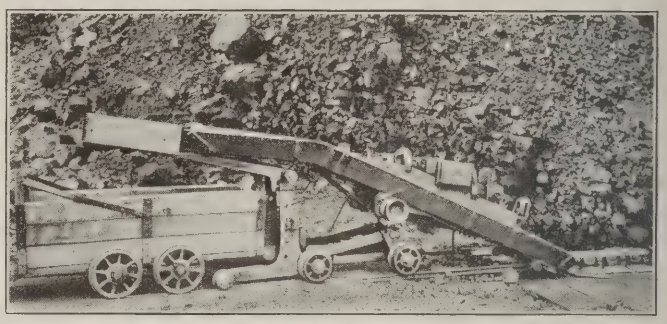

FIG. 4. SIDE VIEW OF FLAT FLIGHT JEFFREY LOADER

hardness of the coal. The knocking-down process ordinarily takes place faster than cars can be supplied. When it is completed the conveyor is pulled back about 7 ft., a section of track is laid, and the conveyor again moved forward into position.

Two set-ups during the shift constitute a 10-ft. advance of the entry. It is estimated that under suitable operating conditions, such as high coal of the quality found in the Pittsburgh bed, the machine should average 250 ft. of advance per month of 25 working days, working day shift only, night shift being reserved for the laying of tracks, piping, etc. Where conditions have been suitable and cars have been served to the machine without delay, as much as 20 ft. of advance has been made in a single shift. The average advance in entries of the Annabelle mine at Worthington, W. Va., where several of these machines have been in operation since 1913, is somewhat over 10 ft. The cuts average 10½ to 11 ft. wide and 6½ ft. high.

In 1913 the Jeffrey Manufacturing Co. built a number of machines based on the patents of E. C. Morgan. The principal elements in this design are the undercutting chain, the two shearing chains, the heavy reciprocating pick that knocks down the coal and the conveyors that carry it back and load it into a car. Fig. 3 shows a front view of the machine, which operates on the same principle as a breast machine, the first, or sumping cut, being made at either rib, usually the left. It is fed forward in a stationary pan, making a cut 5 ft. wide, 7 ft. deep and of a height to suit the seam. The machine has an undercutting chain with cutter head similar to that of a breast machine, and a shearing chain on either side. The frames carrying these shearing chains can be varied for different heights of coal.

Between the shearing chains is mounted a frame carrying a number of heavy punching picks. This frame is readily raised and lowered by the operator, who can cause the picks to strike at any height he desires. The coal falls onto a conveyor which is made thin enough to go into the kerf cut by the undercutting chain. This conveyor carries the coal to the rear end

of the machine and dumps it into a second conveyor, which is mounted so that it can swing at any desired angle to the machine.

After a cut is made, the machine is moved sideways by means of a rope hitched to a jack at the opposite rib, and then another cut is made. When slate is to be piled up at the side of the room, the rear conveyor is swung sideways, the slate rolled onto the front of the machine and gobbed by the two conveyors.

In a test run the machine required an average of 13½ min. to make a cut and about 3 min. to move the machine to the next cut, or about 16 to 17 min. time for each cut. The coal loaded averaged 21 tons per hour, although where roof conditions were good the machine has loaded 30 tons an hour. The height of the coal is 5 ft. 8 in. In another district an average of 60 tons per day was had for three months. In the driving of an 11-ft. entry it has averaged 20 ft. advance per shift of 8 hours under rather unfavorable circumstances. Figures show a saving of 32c. per ton by using the machine for entry driving. The crew for each machine consists of a machine runner, a helper and a driver. If the slate is heavy it may require an extra man for its handling.

In spite of the attractiveness of the combination mining and loading machines as labor-saving devices, they have so far failed to gain a prominent place in the sun. One trouble with them would appear to lie in the large number of working parts. In the next place, a combination type of machine is necessarily cumbersome and is moved with difficulty from place to place, even though such movement is not often required. Again, in spite of the care taken in design, failures due to breakage of vital parts are sure to occur.

Combination shoveling and loading machines as a type consist of a shovel or similar device, to pick up the coal after it has been shot down, and another device, as a belt, to convey it to the mine car. It therefore occupies a position midway between the combination mining and loading type of machine and the plain conveyor.

The Hamilton machine will be the first treated of this type, for the reason that it was one of the pioneers in its line. The Hamilton loader, in its original design, consisted of two conveyors, the rear one serving for

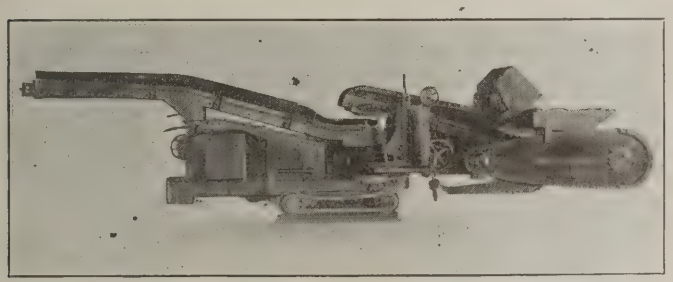

FIG. 5. MYERS-WHALEY SHOVELING MACHINE

gathering the coal and moving it to the front conveyor, which carried it to the car and also served as a picking table. The front conveyor was permanently mounted on a truck; the rear one, when necessary to move the machine to another location, was mounted on pony trucks. The entire machine was self-propelling and on reaching the face the rear, or gathering, conveyor was jacked up and the pony trucks removed, permitting the nose end of the conveyor to rest on the floor.

A novel feature of the first machine was that after the flights passed around the sheave wheel they folded up and entered the return guide pressed back against the chain, the advantage claimed being compactness, and that this prevented pushing the lumps off the car as it was being filled. In the later design this feature was discarded, the flights remaining stationary with respect to the chain.

The operation of this improved type is as follows: The coal being undercut and shot down, the loader is run to the working face of the room, after which the

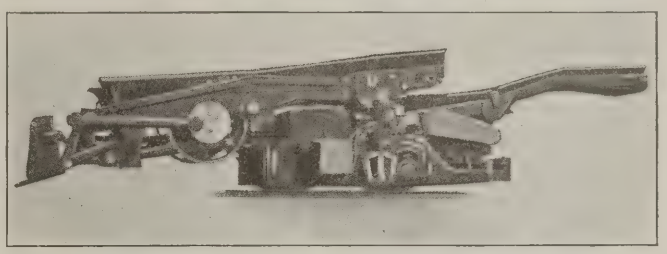

FIG. 6. VIEW OF HALBY SHOVELING MACHINE

pony truck is removed and the gathering conveyor let down upon the mine floor. Adjustable mine posts are set, one at either side of the room, as near to the mass of coal as possible. The ends of the feed chain are then slipped into hooks located at the bottom end of the posts, the feed motor is started, and the nose of the conveyor, which lies flat on the pavement, is swung to one side of the room.

The pit car being placed in position under the picking table, the machine motor is then started, moving the flights in the proper direction to gather coal. The machine is then moved forward by its own power into the pile, making a hole at one side of the room 3 or 4 ft. deep.

The machine is now ready for its movement across the room, which is effected by winding on the feed chain attached to the second post. As the radial sweep travels in its arc across the mine floor, the flights pick up and carry away all of the material lying in its path. The machine will gather lumps of coal as large as will pass between the roof and the top of the car.

After one sweep across the room, the machine is again advanced into the pile, the direction of the conveyor chain reversed, and the operation of the first cut repeated, with the coal going up the trough on the other side. The travel of the conveyor is 80 ft. per minute, and when the trough, which is 12 in. wide, fills 6 in. deep with coal, the machine is loading 2000 lb. per minute.

A haulage reel on the machine carries a cable which is placed around a sheave and serves to pull the loaded cars from the loader to the roomneck. When cars are unusually large, double reels may be used and operated on the main-and-tail rope system, handling both loads and empties to and from the machine. The time required in moving the machine from place to place and setting up is stated as not exceeding 20 to 30 minutes.

In 1909 a machine was designed and built by the Jeffrey Manufacturing Co. under certain patents owned by the Hamilton interests. It has flat flights without any obstruction. These flights slip under the coal in the same manner as a shovel and pick up the coal without any difficulty and with little hand shoveling necessary. In the driving mechanism for the conveyor is a

friction clutch that works very satisfactorily. If the conveyor happened to be forced against the rib, for instance, or the flights encountered any obstruction, the conveyor would simply stop, thus protecting the machine from breakage. The conveyor is pivoted over the car. The loader is pulled into the coal pile by means of ropes leading out from either side of the conveyor.

The Hamilton machine, in its original and improved forms, was experimented with for two to three years in various coal fields. It loaded coal at the rate of a ton a minute. It picked up the coal and left the floor practically clean. It would load extra large lumps, was easily handled and fairly free from breakdowns. To all appearances a machine had been produced which possessed every requirement, and was capable of loading at a rate equivalent to the work of ten men. But in spite of its good features it did not prove to be a success, largely because existing conditions in coal mines rendered it impossible to keep the machine in continuous operation.

The Myers-Whaley machine is mounted upon a main frame, supported by four flanged wheels running on the main track. A jib section is pivoted upon the front end of the main frame, so that it can swing laterally 45 deg. each way. This jib section carries the shovel and the front conveyor which receives the material from the shovel. Also pivoted at the same point on the main frame is a rear conveyor frame which is adjustable laterally, and the conveyor which receives material from the front conveyor and discharges it into a mine car. The seat for the operator is mounted on the jib section in such position that he can see in front of the shovel and direct its operations. The swinging of the jib laterally enables the machine to reach 10 ft. to each side from the center of the track, or a total width of 20 ft.

The shovel is entirely automatic in its action, and is a unique piece of mechanism consisting of a shovel member 34 in. wide, having an auxiliary, or rear section, fitted into it. The shovel is actuated and supported by a crank which rotates continuously, and which is driven by heavy roller chains on each side of the machine. The rear end of the shovel is carried by a cross shaft having rollers on its ends which run in cam grooves, so as to give the mouth of the shovel a motion similar to that of a shovel actuated by hand. The front part of the shovel discharges into the rear section, which has auxiliary cam rollers engaging in another cam groove and which turns the rear section partly over during each stroke. In this way the material is picked up and transferred to the belt conveyor. This crank rotates at a speed of 12 to 13 times per minute.

The No. 2 machine, the smallest model, has a height of 46 in., length 19 to 21 ft., width 4 ft. 9 in., net weight 9000 lb., and requires a mine height of 54 in. The No. 4 machine, the largest model, has a height of 54 in., a length of 22 to 26 ft., weighs 18,000 lb., and requires a mine height of 72 in. The largest machine is capable of loading coal at an average rate of one or more tons per minute, and is driven by a 20-hp. motor.

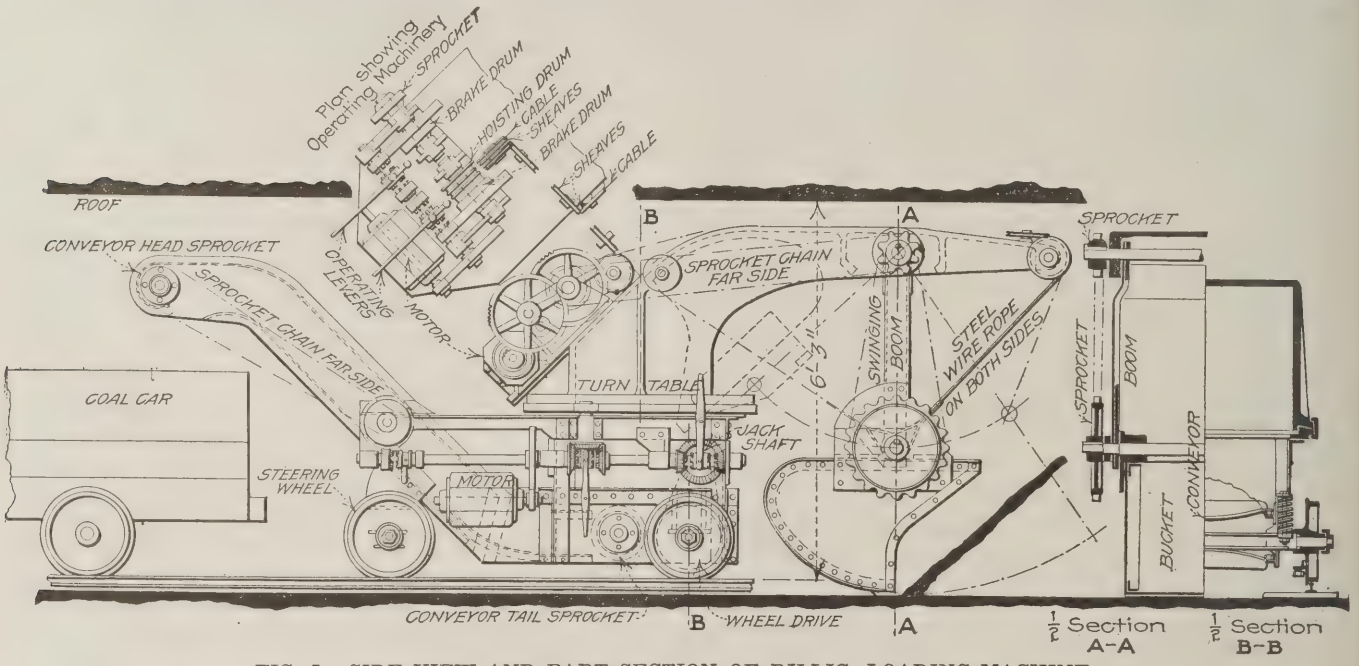

FIG. 7. SIDE VIEW AND PART SECTION OF DILLIG LOADING MACHINE

It will be evident that the room-and-track system employed is susceptible to variation and should be worked out at each mine in order to secure the best results. The swinging of the rear conveyor laterally enables the machine to load cars upon the track directly behind or upon a track closely parallel to the machine track.

The Halby machine is furnished in two standard coal models. The T-600 machine is designed for use in mines which permit of 6½ ft. or better headroom. This model is used where such headroom is available because of the fact that it permits of a high car under the rear conveyor. Its weight is 20,000 lb. The T-700 machine is designed especially for 5-ft. coal and may be used where there is a height of 5 ft. 6 in. from floor to roof. In this latter model the rear conveyor is so arranged that it will permit of the material being discharged on cars directly behind the machine, or on a track parallel with that on which the machine is operated.

The Halby machine is essentially a shoveler and loader, designed to operate under its own power, forward and backward on a track, with a shovel motion so devised that it makes an advance of about 10 in. into the coal pile, much after the fashion of a man in load-

ing. However, the principle of operation is such that in addition to the advance of the dipper through its motion and through the path of its travel, it is assisted by a simultaneous advance made by the machine itself on the tracks.

The mine car is coupled to the machine, whenever it is being loaded on the same track, and thus the machine and the car are moved together. As the dipper comes to its downward advancing position, the operator, who rides on the machine, advances the machine itself, and as the dipper is returning in its path, he likewise backs up. The dipper makes approximately ten turns per minute, and its capacity is such that under ideal conditions it would be possible to load a ton of coal in even less than a minute. However, as a general average, it requires about 2 min. to load a ton.

The operator, at the same time that he is moving the machine forward and backward, is enabled by the operation of a lever, and with practically no exertion, to move the dipper from side to side, and thus clean up approximately 7 to 8 ft. on each side of the center of the track. The machine is so arranged that it may advance with the dipper in motion, and at the same time swing to either side of the track, simultaneously discharging into a car at the rear, or on a track parallel with that on which the machine is standing.

Shovel Motion of Halby Machine

The propelling speed of the T-700 machine is 110 ft. per minute, and of the T-600 is 100 ft. per minute. The belt speed of the two types is 85 and 120 ft. per minute respectively. Either model will handle coal in large sizes, pieces weighing 1500 lb. being readily lifted on the dipper. The distinguishing feature of the Halby machine lies in its shovel motion, which is such as to permit a smoothly sliding discharge onto the belt.

The Dillig machine (see Fig. 7) is the invention of George Dillig, of Pittsburgh, and is unique in that it adapts, to a low-height mechanism, a shovel somewhat similar to that found on large power shovels. The machine consists of a low frame mounted on four wheels and provided at the top with an open circular track, or turntable, upon which is positioned a revolving outrigger. It is further provided with a conveyor arranged to receive the material immediately beneath the central opening in the turntable, and which conveys the coal and discharges it at the far end of the machine into mine wagons.

The revolving outrigger, mounted on the turntable, carries near its overhanging outer end an oscillating or swinging boom, controlled by means of cables operated by an electric hoisting apparatus shown mounted on the back of the outrigger. To the lower extremity of this oscillating arm, or boom, is attached a bucket, or scoop, free to revolve about its pin center, but controlled by means of a sprocket chain drive, also driven by the electric hoist.

The operation of the machine is as follows: The machine is properly positioned close to the materials to be shoveled; the hoisting cable pulls the swinging boom, with the bucket digging or shoveling, to a limiting forward position. At this point the bucket is made to revolve about a quarter turn or so, in a counter-clockwise direction, around its own pin center. With the bucket now filled and in a turned-up position so as to prevent the coal from spilling, the operator reverses the cable drum and the boom is swung back and carries the bucket to a dumping position, immediately over the centrally open turntable. Here the bucket is given a further counter-clockwise rotation, causing the material to be discharged through the turntable opening to the conveyor beneath. Immediately after the discharge the bucket is given a clockwise rotation and righted, while at the same time the boom swings forward again to attack the pile, and the cycle of operation is repeated.

The arrangement of the outrigger mounted on a turntable and free to move to the right or left of the machine permits the gathering of coal within an arc having a radius of 15 ft. The machine is electrically operated and self-propelled, and weighs 8000 pounds.

Machines belonging to the portable loader class are intended to simplify the manual labor of loading, rather than to displace it. It is a fact, too frequently forgotten, that the height through which the shovel must be raised determines the capacity of the loader. Thus, with the same expenditure of muscular energy to raise the coal, a man will load 29 tons into a wagon 52 in. above the rail, 44 tons into a wagon 32 in. above the rail, and 140 tons into a conveyor 8 in. above the floor, allowance being made for clearance in each case. But impressive as these figures may be, they still do not adequately bring out the advantage of loading into a conveyor over loading into a mine car, for in the act of raising the shovel, the foot-pounds expended in raising the body is greater than the foot-pounds exerted in lifting the coal. When loading into a conveyor coal does not have to be lifted more than a few inches; some of it can be rolled or pushed on, and all in all a tremendous saving in muscular energy is effected.

Construction Details of Westmoreland Loader

The Westmoreland loader is built according to the design of W. W. Jamison, of Greensburg, Penn. It weighs 10 tons, is electrically operated and self-propelled. The truck is rigid, with 12-in. wheels, one front wheel with loose axle, 4-ft. wheelbase, and when in operation the truck is clamped rigidly to the rail. A 3-ft. geared turntable rests on the truck frame, and on this is mounted a solid steel case, 12 ft. long, 32 in. wide and 12½ in. high, which swings free above the wheels through an arc of 160 deg., 80 deg. right and 80 deg. left, the width of sweep being 16 feet.

The steel case contains a ram in the form of a chute, 2 ft. wide, 6 in. deep above the floor, and with an adjustable shovel end at the front. The ram-chute hangs on rollers and is moved forward and backward by a rack and pinion at the top. This represents the unique feature of the machine. This ready horizontal movement of the ram, together with its sweep of 8 ft. on either side of the machine, enables it to keep close to the loose coal throughout the full 16 ft. or slightly more of width, and thus facilitates the work of the laborer.

The adjustable shovel end of the machine takes care of undulating bottom. It is rigid in operation for all sizes of coal, fine slack up to 200-lb. lumps being picked up at the rate of one ton per minute by the chain conveyor in the ram. The actual rated capacity of the loader under fair conditions is 20 tons per hour. Five men are required for its operation, this including the driver. The machine will work in seams that are not

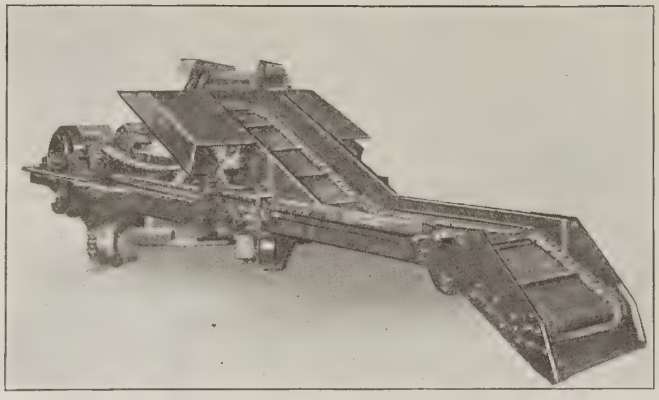

FIG. 8. WESTMORELAND LOADER, SHOWING SWEEP OF RAM

less than 4½ ft. thick, and will pass over curves of as low as 12-ft. radius. The total power requirement is 16 hp., consisting of three reversible motors.

The Jeffrey pit-car loader is a simple conveyor, light in weight and so balanced in construction that it is easily movable across a room. It is driven by an electric motor, so located as to add to the stability of the machine. This device is so simple that it has the distinction of having no distinguishing features in its construction. Its novelty would appear to lie in its cost, which is about one-seventh that of a shoveling machine. It will doubtless appeal to those who contend that coal mining is attended with too many delays to tie up larger amounts of capital in expensive machinery, and attract those who fear that the mine is no place for a machine designed to pick up the coal.

The claim of its maker that the output from a room can be doubled by the use of this machine appears to be conservative. The fact that it requires only two men to operate, whereas other machines require from four to eight, is vastly in its favor, for when the inevitable delays occur it is not difficult for two men to find useful work, in posting, extending track, etc. Quite a number of these machines have been in operation at the mines of the Dominion Coal Co., Canada, some of them for a period of three years, and it has been proved that two men will average from 50 to 75 tons per shift. For moving from place to place the machine is mounted on a small truck.

The Evans scraper loader is the invention of Cadwalader Evans. This device is nothing more or less than an adaptation of the old main-and-tail rope principle to the operation of a modified scraper (equally old) as a means for conveying the coal from the face and out to the roomneck, where it is dumped into the car.

The apparatus consists of a double drum hoist, which may be driven by either air or electric power, two wire ropes of suitable lengths, and a V-shaped bottomless scoop, or drag. In addition to this major equipment, each room is provided with deflectors, loading pans and aprons. All coal is loaded on cars in the entry, the plan being to set a trip of empty cars above the roomneck so that no time will be lost in spotting another car when one is loaded.

In the use of this device, present methods of cutting and loading are followed until the first crosscut is made at a distance of about 20 ft. from the entry. After this is made the scraper may be employed for loading the coal from the entire set of rooms thus connected by crosscuts, as it is through these that the cutting machine passes from place to place. The reason for following present methods of loading until the first crosscut is made is on account of moving the cutting machine, as it will be seen that with the short wooden inclines built in each room and necessary for elevating the coal preliminary to passing into the car, the entrance to the room is obstructed. In passing along the length of a room, or through the crosscuts, the cutting machine moves under its own power or can be drawn by the hoist ropes. There are no rails in the rooms.

The hoist is set in a pocket cut into the entry pillar, preferably midway in the room block that is to be worked. The hoist remains here until the block is worked out, including the drawing of the pillars. At the mouth of the pocket lead sheaves are placed, these sheaves usually being built in sets of three or four so that the ropes may be led to the right or to the left, to the room that is ready to be loaded out.

A part of the permanent equipment at each roomneck consists of two sheaves, mounted on suitable brackets for attaching to props, and used for leading the ropes across the entry and over the car to the face. The tail rope is led up the gob side and around a sheave attached to a jack screw, similar to a mining machine jack, and located near the right-hand corner, and is then fastened to the back of the scoop or drag. The main rope passes around a similar sheave at the left-hand corner and passes to the front of the scoop. It will be apparent that the object of attaching the sheaves to jack screws is to facilitate resetting as the face advances.

At each roomneck loading pans and aprons are installed and are not moved until the block is worked out. Where the coal is high it is necessary to construct a wooden incline, probably 20 ft. long. Where the coal is low and the bottom is taken up in the entry, this incline becomes unnecessary.

The scoop, or drag, is of sheet steel, V-shaped and bottomless. As the scoop is being pulled along the face it picks up its load, and when filled the main rope is removed from the sheave and the hoist starts drawing the scoop to the incline. Here the scoop discharges without the necessity of tipping. After discharge the hoist is reversed and the tail rope pulls the scoop back into position for another cycle. The scoop is flanged at the bottom so that it will avoid digging into the floor.

FIG. 9. VIEW OF THEW ELECTRIC SHOVEL LOADING ON ONE TRACK

It is figured that with rooms of 300 ft. length it is possible to load at least nine tons of coal per hour. The average haul in this case amounts to 150 ft., and the hoist being geared for a rope speed of 300 ft. per minute, the traveling should be done in 1 min. actual running time. Assuming that a minute is lost at the face and another minute at the loading point, there would be 20 trips per hour, which on a basis of 900 lb. per scoop amounts to nine tons. It requires five men to successfully operate the apparatus—one hoist man, one man on the entry to spot and trim the cars, two at the face and one timberman.

The Evans loader has the following advantages: (1) It requires no track in working places after the first crosscut is made, hence it eliminates a considerable labor and material expense; (2) it uses no complicated mechanism, but instead such components as are familiar to all mining men; (3) because of its simplicity delays are few and repairs light, it being quite likely that rope renewals will be the most burdensome item owing to the sharp bends in passing over sheaves; (4) is simplifies the problem of replacing loaded cars quickly with empties; (5) is can be worked in seams of practically any height, although more attractive to low-seam operation than to high; (6) the system is not affected by seams of moderate inclination; (7) in case of falls of roof little or no injury can result since the destructible element, the hoist, is away from the room; (8) it is flexible and can be easily adapted to the drawing of pillars.

Its disadvantages would appear to lie in that (1) the capacity of the system is low; (2) the abrasion of the coal in the scoop as it passes over the bottom, along with the churning of particles, causes degradation of the product; (3) the power consumption in dragging the scoop over the floor and in moving the cutting machine from place to place is large.

Preceding their use in mines power shovels have been used in the construction of tunnels for many years and have demonstrated their practicability for this kind of work. Because of their dimensions the employment of this type for underground loading of coal has been restricted so far to seams of unusual thickness. The Mammoth bed of the anthracite region would appear to be adapted for the use of power shovels were it found horizontal instead of pitching. The bituminous states of the East and Middle West have no beds that yield the required headroom; and it is not until we reach the bituminous and sub-bituminous coals of the Rocky Mountain states that deposits of sufficient thickness to permit the use of shovels may be found.

It is well known that beds of extraordinary thickness occur in Wyoming, and although not ideal because of their pitch, they are in all other respects well suited to this type of loader. The electric shovels are being used by the Union Pacific Coal Co. in the mining of a bed of bituminous coal 30 ft. thick belonging to the Rock Springs group of the Lower Mesa Verde formation.

The contemplation of any device that promises to make two tons of coal appear where but one appeared before, has a fascination all its own. In its development discouragements will be patiently met and endured. It will hearten us to know that the preceding innovations have, in almost every case, been attended with ill success initially, but that the early failures merely served as a goad to those inventive geniuses who refused to

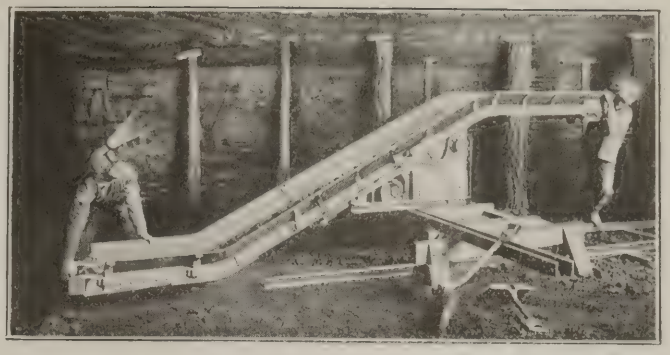

FIG. 10. MOVING JEFFREY PIT-CAR LOADER INTO A NEW POSITION

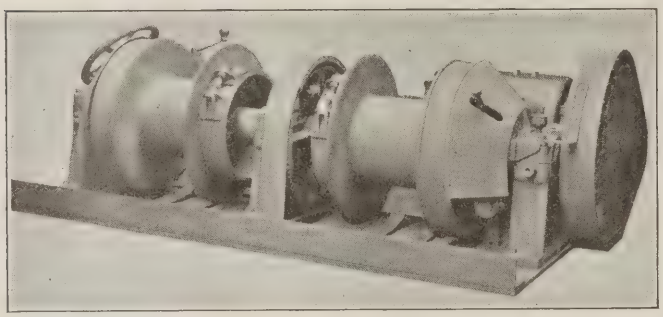
lose faith in the soundness of a principle. An improvement here, a strengthening of parts there, along with a change in mining practice, have all combined to overcome the primary defects in every device employed in mining from the ancient atmospheric engine to the modern storage-battery locomotive. We are due to witness again the same persistence, in fact much has already been done. The years spent in patient investigation and experimentation, plus the hundreds of thousands of dollars which have been expended in the development of coal-loading machinery, is already bearing fruit, and will result, I believe, in making these devices as common in mining practice, within the next decade, as is coal-cutting machinery and the electric locomotive at the present time.

What will be the machine of the future? Notwithstanding the varied appliances now on the market, the weight of mining opinion has not settled as yet on any one machine as the prevailing type. Nor is it likely to, for the various principles which can be applied successfully to coal-loading machinery, in combination with varied mining conditions, will result, I believe, in the introduction of a variety of types.

In closing it may be entirely unnecessary to caution against installing coal-loading machines of any kind unless the mine is prepared in advance to receive them, and yet, from the experiences of the past it is clear that the importance of this has, too frequently, been either overlooked or else underestimated. It is manifestly unfair to any machine, and unfair to the capital invested in it, to harass its operation with a poor haulage system or an unfavorable method of development. Let us ever remember two things: First, that while machinery has utility it produces revenue only while it is at work, and second, that unless all underground activities operate in harmony, so that petty delays are avoided, no device can achieve the results rightfully to be expected from it.

Coal Mining Equipment in France



The secretary of the American commercial attaché office at Paris, France, reports as follows under date of Jan. 3: Regarding the matter of reconstruction of the French coal mines, Mr. Cuvelette, Director of the Coal Mine Group of the Comptoir Central, writes this office that all purchases of coal-mining equipment made in the United States will be handled through the Franco-American mission, directed by Mr. Tardieu in Paris and by Mr. De Billy in New York, and that American firms must ultimately address themselves to the office of the latter for the purpose of bidding on mining material.

Electric Winding Machine

By E. M. Mackie
Syracuse, N. Y.

The problem of economical loading of thin-bed coal for a long time has been awaiting a satisfactory solution. In this connection there has recently been under development in the anthracite fields systems of loading by pan and by scraper conveyor. In the bituminous field also some experiments have been made, but the development in these regions has been slow, chiefly because of the winding machines that have been employed.

The main idea in these systems is to eliminate as far as possible the manual handling of the coal, after it has

BACK VIEW OF ELECTRIC WINDING MACHINE, SHOWING WINDING DRUMS

been broken out of the seam. Either system above mentioned consists of a pan or a scraper having a cable attached to each end so that the device can be moved forward or backward as may be desired. To actuate the conveyor a winding machine with two drums is necessary, one drum to wind on and the other to reel off cable. Each drum must be so arranged that it will reel off or wind on the rope, depending on the direction in which it is desired to move the scraper or pan.

From the foregoing it will readily be seen that the winding machine is highly important to the successful operation of these systems. The first experimental trials using such standard makes of winding machines as were available satisfactorily demonstrated the possibilities of these new methods, provided a suitable machine could be developed. The most important requirements are as follows:

1. The highest possible rope speed consistent with safety.

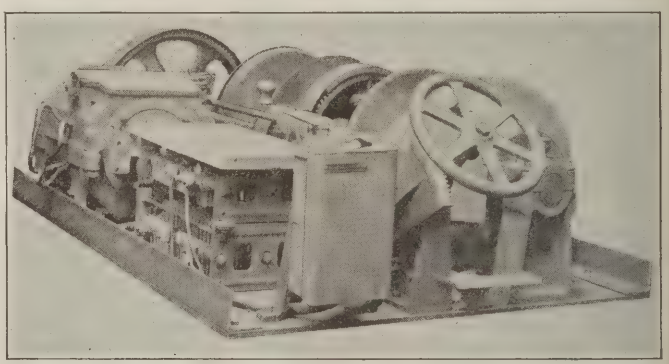
2. A friction drive is necessary for the winding drums, and this drive must be so designed that the friction can be set for a wide range of loads. There must be no slippage when pulling, but slip must occur within a given per cent. of overload.

3. The engagement and release of the drum drives should be accomplished with one continuous movement of the engaging mechanism, in order to prevent locking of the drums and to make possible the instantaneous reversal of the conveyor at the instant of dumping. In loading from a room about 200 ft. deep, this feature of instantaneous reversal saves time equal to one-third of the total required for one round trip of the conveyor.

4. The engagement mechanism should have a neutral position; that is, a position in which both drums are disengaged and will turn freely on their bearings.

5. Each winding drum should be provided with a brake operated by a foot lever, so that in case of cutting off power to stop the hoist, or for any other reason, this foot-operated brake can be set on the reeling-off drum to stop it and thus prevent over-running and consequent fouling of the cable. Furthermore, the operating mechanism of the foot brakes should be so arranged that these brakes cannot be set on both drums at the same time. It should also have a neutral position in which both brakes are free of the drums.

6. The overall height of the winding machine should be not more than 30 in. from the bottom face of the base plate.



7. The whole arrangement should be as nearly foolproof as possible.

To meet the foregoing requirements the Pneumelectric Machine Co., of Syracuse, N. Y., designed and developed the winding machine illustrated. The machine is mounted on a heavy steel-plate base. No bolt heads, nuts or other projections protrude from the under face of this base plate. Thus there is a smooth, flat underface which facilitates the moving of the machine from one location to another.

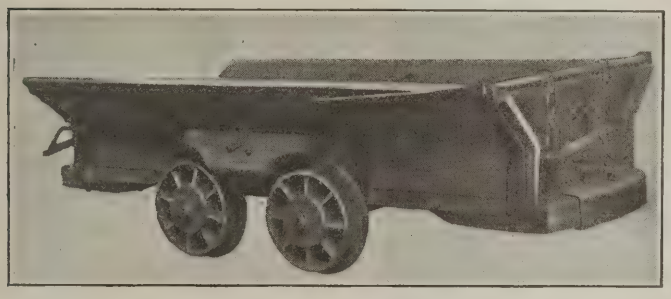
Both drums are of the same dimensions and are interchangeable. Drum and intermediate shafts run in bronze bearings which have spherical seats in the housings, insuring free running of the shafts. The bearings are interchangeable on each shaft. The gears and pinions are of steel and the teeth are machine cut. The drum shaft gear is made in halves, thus providing for easy replacement when necessary.

The friction-clutch drive for the drum is of a design not heretofore used for this purpose. It embodies features that make it possible to handle the load in a manner highly essential to the successful operation of these systems, means being provided for automatic loading and unloading, so that the operator is relieved, by levers or otherwise, from regulating this part of the operation.

The elements employed for engaging or releasing the clutch permit the operator to maintain a natural position in a limited space while making the continuous motion in one direction necessary for the engagement of one clutch and the release of the other. This ac-

FRONT VIEW OF ELECTRIC WINDING MACHINE, SHOWING CONTROL EQUIPMENT

complishes the immediate reversal of the scoop at the instant of dumping.



All bearings have ample provision for lubrication with grease, and the gears and clutches are protected by substantial guards. The machine shown is equipped with a 25-hp. motor for 220/250 volts, direct current, and weighs approximately 5000 lb. The overall dimensions are: width, 4 ft. 8 in.; length 7 ft., and height, 29 in. A number of these winding machines are now in successful operation.

Advantages of Standardization of Mine Cars

By H. V. Brown
Cherry Tree, Penn.

In times past, the design of mine cars for any particular operation was a matter that was put into the hands of the engineer, superintendent or foreman in charge of the mine. No thought was given to the importance of using a standardized mine car suited to local conditions, nor to the fact that it is practically impossible for one man, no matter how capable, to work out a new design that will incorporate every possible good feature and be entirely satisfactory in every respect.

We are now in a period of standardization in machinery of all kinds, and there is just as strong reason for maintaining standards in mine cars as in any other piece of mining equipment. The manufacturer who is regularly in the business of building mine cars and who has given careful thought to the development and improvement of his product can in practically every case propose a design to meet certain specified conditions that will be more advantageous than any that can be worked out by a single mining engineer. The reason for this is obvious because the manufacturer has the advantage of experience with different designs and is

THIS STANDARDIZED MINE CAR IS SUITABLE FOR USE IN THIN VEINS

able to eliminate bad features and incorporate those that are desirable.

There is, of course, a wide diversity of opinion between different mining engineers as to the proper dimensions of cars for a certain condition, also as to the proper weight of irons and other details. Many cars are built extreme, either as to lightness or as to weight. As an example, consider the average thin coal bed that will run from 30 to 48 in. in thickness. It is obvious that for this size of vein there are a few designs that are really practicable and efficient. Nevertheless, if one were to study the cars used in various mines operating this thickness of coal he would doubtless find a great number of designs, each embodying some good features, but many undesirable ones. It is here that the importance of standardization and coöperation with the mine-car builder is evident, because in practically all cases a more satisfactory design can be worked out and at a lower cost than if the user is to attempt to specify all the details of his car.

The Cherry Tree Machine Co. has been working along this line of standardization for the past two or three years and has been successful in standardizing several designs, one of the most important of which—a design suitable for thin veins and locomotive haulage—is illustrated. About 2000 of these cars have been placed in service and the design has been found practicable in over twenty mines, all of which have generally similar conditions and heights of coal ranging from 33 to 48 in. This particular car was designed after a careful study of a number of successful cars used in thin-bed work and incorporates every good feature that could be found. The car as built holds practically one net ton when levelful, and when full-loaded will carry 1¼ to 1½ tons, dependent upon the height to which it is topped. The over-all dimensions have been kept within reasonable limits and the iron sizes have been carefully worked out to give the greatest strength with the least weight. The car is admirably suited to locomotive haulage and at the same time is capable of being easily handled in the working place by the miner, as it weighs only 1500 lb. The truck construction is such that the alignment of the wheels and axles is preserved.

The most important advantage of standardization is, of course, that of securing an entirely satisfactory design, suited to the conditions; but there are other advantages to be gained which are well worth careful consideration. Some of these are as follows:

Standardized cars can be purchased at a lower price than special designs, because of the fact that the mine-car manufacturer has developed the production of such cars and has worked out the special dies and fixtures necessary to reduce construction costs; furthermore, he is in better position to purchase material to advantage, especially steel bars, since the item of waste in cutting, etc., can be greatly reduced.

The manufacturer building standardized cars can develop punching and drilling jigs, etc., which make it possible to construct these cars with interchangeable parts and in addition assure their proper assembly, so that the car will be true to gage, perfect in truck alignment and correct as to general dimensions.

Another point in this connection is that the small user who may desire to purchase only five or ten cars at a time is enabled to secure a standard design at a considerably lower cost than a special one, because of the fact that the manufacturer can build these cars on stock orders and is thus in position to sell them in small lots as other standardized machines are sold.

Spring Meeting of the Illinois Mining Institute

At a recent meeting of the executive committee of the Illinois Mining Institute it was agreed to hold the next regular meeting on May 22 to 24, inclusive. Later the Southern Illinois Superintendents' Association requested that this meeting be held on a steamboat on the Mississippi River. An option was secured on the steamer "Golden Eagle," which will expire on May 10. It was agreed to make the trip from St. Louis to Keokuk and return, the boat to leave St. Louis on Thursday, May 22, at 10 a.m. and return to St. Louis, Saturday afternoon, May 24; or, if desired, on Sunday morning the 25th. The price for the round trip per person is $27, which includes meals and berth for the continuous round trip and "Dutch lunch" to be served about 11:30 each evening. The boat will accommodate 150. If enough people signify their intention to take this trip to make it possible to secure the boat then a schedule will be arranged. It is said that the program of papers that is being arranged for this meeting is as good as any that has ever been prepared for the Institute.

Storage of Powder and Explosives at Coal Mines

By E. M. Kimball
Wilmington, Del.

EFFORTS have been made by powder manufacturers for a number of years to induce the miner to pay more attention to the proper storage of his explosives. It has been more or less assumed that any place was satisfactory, and explosives have been kept at any old out-of-the-way point, in a cheap building, or in an old abandoned shed around the property. Often they were stored in pits excavated in a hillside or in some abandoned tunnel. This is continually being noted, and has recently been brought forcibly to my attention in a visit to the coal fields of southern Indiana, West Virginia, western Pennsylvania and Kentucky. The operators, while neglecting their magazines, are at the same time spending large sums of money on their plants and machinery. The first point considered by the operator is, of course, one of economy, but improper storage is poor economy in connection with explosives. The first cost of the magazine is all that is considered in the majority of cases. It seems quite possible that the powder manufacturers themselves are partly responsible for this condition, because of their liberality in the matter of claims. If the explosives go bad, the operator makes claim and this is quite often allowed, even though the maker is reasonably satisfied that the cause of the trouble is not some fault of manufacture but the result of improper storing. On this account the operator does not always recognize his actual financial loss due to improper storage.

MAGAZINE BUILT ON A BRICK FOUNDATION

It should be appreciated that such improper storage brings about a more or less gradual deterioration in the explosives, and this deterioration results in a loss of power. Considerable loss of strength, therefore, may result without the operator becoming aware of it. These losses soon exceed the cost of a properly located and constructed magazine.

The most common fault with the average mine magazine is the lack of protection against moisture being absorbed by the powder. With dynamite excessive changes of temperature or moisture will cause leakage of the liquid base of the dynamite or permissible explosive, and just insofar as this liquid base leaks away or is concentrated in one portion of the cartridge just so far is there an actual financial loss to the operator.

Aside from the question of the proper type of magazine for the maintenance of the proper quality of the explosives themselves, there is the question of location of the magazines as a matter of safety. This point is also often ignored. The tendency is to put the storage house where it is most convenient and "take a chance." All magazines should be located so as to comply with the local and state laws and ordinances, but if laws do not exist they should be located in compliance with the American table of distances, a copy of which will be furnished by any powder manufacturer on request. This table of distances is based on past experience as to the effects of the detonation of various quantities of explosive at various distances, and a permissible distance from dwellings, public railroads and highways is given for all ordinary amounts of explosives. In considering a location for a magazine an operator has to obtain accessibility to the point of consumption, but the safety and suitability of the location should also be given careful thought. In regard to the latter point, low, damp or swampy places should be avoided if possible. It cannot be overemphasized that storage in a cave or tunnel is probably the most objectionable. The question of guarding the magazine against theft may or may not be important, depending upon the conditions at the mine. In the majority of cases, however, a substantial door and a proper lock are advisable, owing to the isolation of the magazine from the ordinary activities surrounding the operation. Good padlocks may be used, but a special magazine lock is by far the best for the purpose. It is believed that the majority of the large powder companies would be glad to quote prices on such locks.

It might be well to outline briefly satisfactory types of magazine construction for the benefit of those interested. If powder, caps or fuse are to be stored, the magazine may be of frame construction and should be fire-protected and ventilated to meet climatic conditions. The following is a brief outline of the construction:

The foundation may be of stone, concrete, brick or posts with enough ventilator holes built into it above the ground and below the floor joists to ventilate the magazine properly. These ventilator holes should have a grating in them to prevent rats and mice from entering and should be built so that an outside fire could not get through into the building. In other words, the holes should not be straight through the wall but have enough angles to stop a flame.

The joists and floor should be sufficiently heavy to hold the load. The floor should be of tongued and grooved boards blind-nailed; no-nail heads or other metal parts should project inside the magazine where it could come in contact with the packages.

Above the foundation the magazine may be of light con-

struction of necessary strength. The outside should be sheathed with ⅞-in. lumber and fire-protected with not less than 26 gage black or galvanized iron. Corrugated asbestos boards may be used. If black iron is used it should be painted and kept painted.

The studding should be sufficiently stiff to resist the load where piles of powder kegs rest against the wall. It is preferable to line the inside of the building with 1 x 6 strips spaced about 6 in. apart, nailed horizontally to the studding, with the nail heads countersunk.

Put sufficient ventilators in foundation and roof. Roof ventilators can be of any standard type, such as the Star or Globe ventilators.

The ground around the magazine should be sloped away from the building to provide proper drainage and to prevent the clogging of ventilator openings.

The door should be made of at least two thicknesses of tongued-and-grooved boards laid diagonally, covered with sheet iron.

If high explosives are to be stored in a magazine it should be bullet-proof, in addition to the requirements given in the foregoing. A bullet-proof high-explosive magazine of course is suitable for the storage of powder or blasting supplies, but blasting caps and electric blasting detonators should never be stored in the same magazine with other explosives. The bullet-proofing of a high-explosive magazine can be accomplished either by a frame magazine, sand-filled, or by building a brick magazine. The specifications for a sand-filled magazine should be about as follows:

Foundations, joists and floor same as specified for powder magazine.

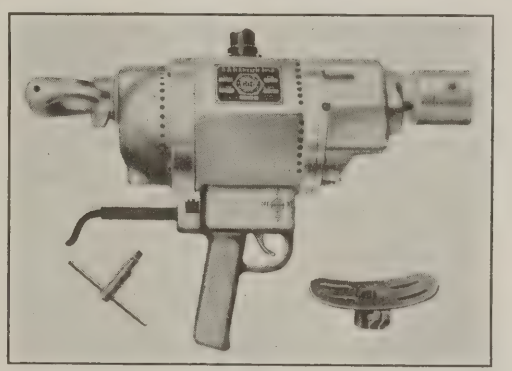
Above the foundations the magazine should be sheathed on the outside and lined on the inside with not less than ⅞-in. tongued-and-grooved boards, the intervening space between to be filled with a weak mortar or with dry sand. If the dry sand is used, care must be taken to have the joists and the boards tight; the lower 6 in. should be filled with a cement mortar to prevent the sand from leaking away. If weak cement mortar is used throughout, a mixture of approximately one part cement to from 7 to 10 parts of sand has been found satisfactory. The thickness of the sand filling depends on the locality. If high-power rifles are in common use from 10 to 12 in. of sand-filling should be used; if such rifles are seldom found in the neighborhood, from 6 to 12 in. of sand will be sufficient. Studding should be placed closely together to carry the weight of the sand. For 6 in. of sand 2 ft. center to center will be satisfactory, where over 6 in. of sand is used spacing of studding should be not greater than 18 in. from center to center.

Where roof can be shot through from surrounding hills, it is well to bullet-proof it also. This can be done by putting in ceiling joists and nailing a second floor upon them, then building a 4-in. rim around this floor and covering it with 4 in. of sand. Where this danger is negligible a bullet-proof roof may be omitted. In warm climates, however, it is well to put in ceiling joists and seal the magazine to assist in keeping down the temperature. In building a bullet-proof roof care must be taken to set back the sand box 2 in. from the wall, in order to provide ventilation between the sand-filled roof and the wall of the magazine.

Specifications applying to a powder magazine in regard to ventilation and outside metal covering will apply to a high-explosive magazine also.

The door should be built of three thicknesses of ⅞-in. hardwood boards covered on the outside with not less than ⅜-in. of steel or boiler plate.

Specifications for a brick magazine are the same as those applying to the sand-filled magazine, with the following exceptions:



Post foundations, of course, should not be used. Sand-filled walls to be replaced by 9-in walls of medium soft brick laid in cement motar. Inside the brick wall 2 x 2-in. furring strips should be placed vertically, and to these should be nailed the 1 x 6-in. lattice lining such as described for the powder magazine.

All magazines should be built sufficiently large to allow ready access to all grades of the explosives stored, so that the oldest stocks can be used first. Any of the large powder manufacturers will be glad to furnish on request and free of cost plans of any of the types of magazines covered in this article. These have been studied by the manufacturer and developed after years of experience. It has been found that the providing of satisfactory storage is of the greatest value, and every effort is being made to assist the consumer to achieve this result.

New Portable Electric Drill Operated Like an Automatic Pistol

The Black & Decker ½-in. portable electric drill shown in the accompanying illustration is equipped with a ½-hp. motor. Its full-load current consumption is about 700 watts, and the no-load speed 600 r.p.m. The housing is of aluminum alloy, completely inclosing the motor and gears, and the total weight of the machine is 21½ pounds.

The most outstanding feature of this drill is its method of control, the "pistol grip and trigger switch," which makes it possible to handle it like an automatic pistol. One pull on the trigger turns the current on and

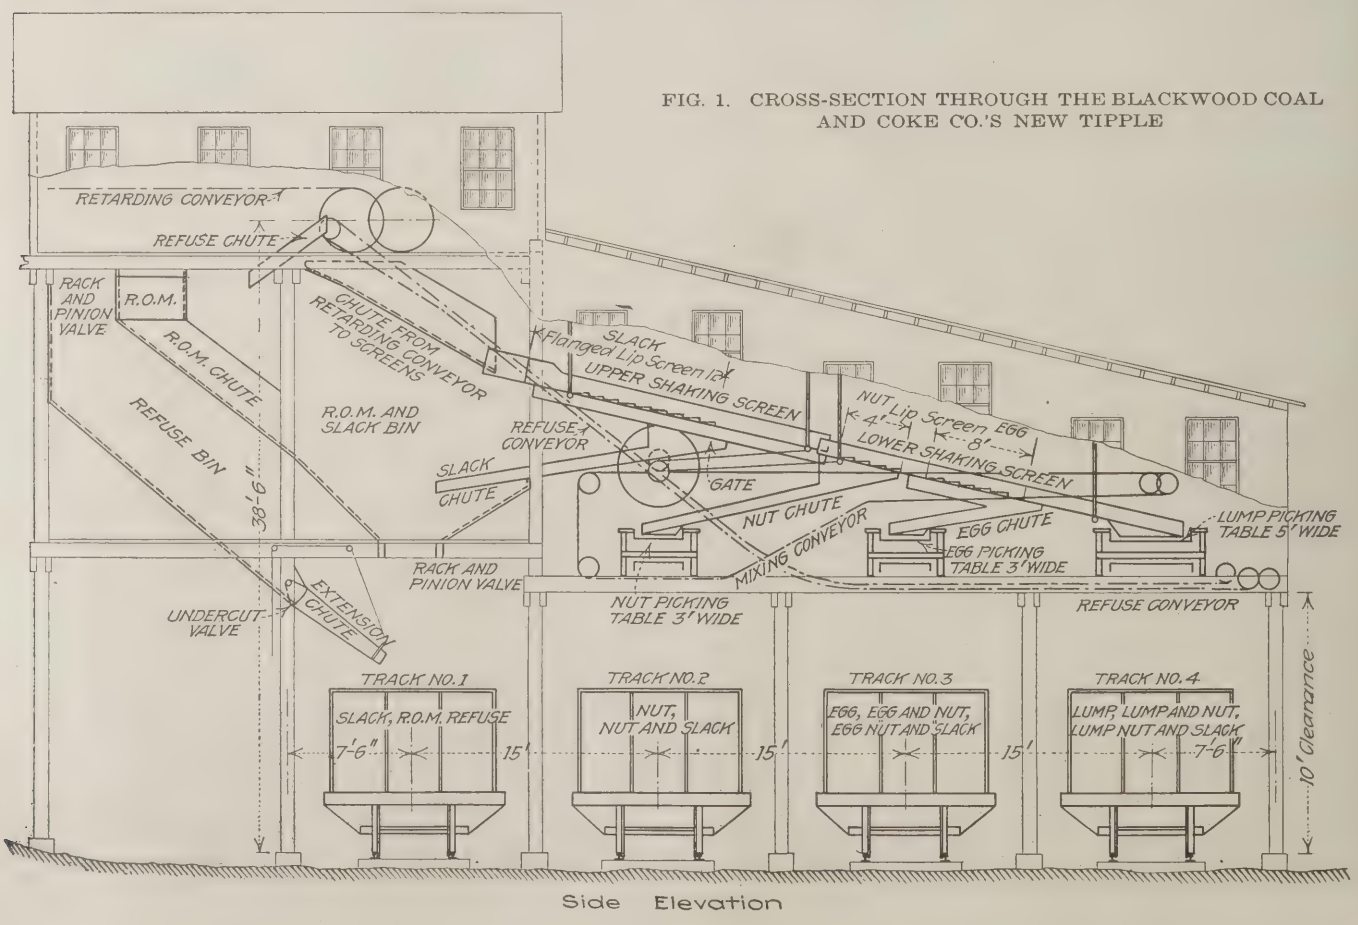
PORTABLE DRILL THAT CAN BE HANDLED LIKE AN AUTOMATIC PISTOL

the next pull turns it off. This arrangement enables the operator to control the drill practically automatically, without having to change the position of his hands in order to manipulate the switch. An indicator is provided for the purpose of showing when the switch is on and when it is off.

The electric motor is of the series compensated wound, interpolar type, and uses direct current or 25, 40 or 60 cycle alternating current, and will operate from any two wires of a three-phase circuit. The motor is air-cooled by means of a centrifugal fan mounted on the armature shaft, which draws air in at one end of the motor and expels it at the other.

The gears are cut from high-carbon steel, mounted on ground shafts, and operate in grease in a separate grease-tight compartment. The drill spindle runs in a long bronze bushing against a ball thrust bearing.

The commutator end cover is entirely separate from the armature shaft bearing, and is therefore easily removable for inspection and adjustment of brushes. This also eliminates the possibility of the armature shaft binding in its bearing, in case the end cover is accidentally distorted by dropping the drill or by exerting excess pressure on the feed screw.



New Coal Tipple at a Virginia Operation

By C. Sharon
Scottdale, Penn.

SYNOPSIS—*Production has been the chief aim of mining companies in Virginia during the past few years. Many tipples have been remodeled while others have been abandoned and new ones built. The new tipple of the Blackwood Coal and Coke Co., here described, is compact yet secures good preparation and embodies means for obtaining almost any grade or mixture of grades the market may demand.*

THE coal fields of Virginia have been the scene of great activity during recent years and have contributed a goodly share of the bituminous coal that this country has been called upon to furnish in the great emergency just past. When the coal operators of the country were called upon to produce their maximum capacity, "Ol' Virginny" came to the front in no unmistakable manner. Surmounting every obstacle, the operators went about increasing their tonnage. They remodeled old tipples whenever they could, or abandoned old tipples and constructed new ones in order to cut down long hauls. The work done by the Blackwood Coal and Coke Co., of Blackwood, Wise County, is typical of this activity. The office of the Blackwood company is at Blackwood, about 5 miles west of Norton, Va., on the Louisville & Nashville and Interstate railroads. The company has coal mines in operation at Blackwood, but by far the greater part of its production comes from the mines at Roaring Fork and Pardee, situated on the Roaring Fork R.R., about 10 miles north of Blackwood.

FIG. 1. CROSS-SECTION THROUGH THE BLACKWOOD COAL AND COKE CO.'S NEW TIPPLE

Side Elevation

At Pardee there has recently been completed a modern plant, the upper headhouse, middle headhouse and a retarding conveyor which leads to the tipple being shown in the headpiece. Coal is loaded onto the retarding conveyor from an upper and lower bed. The equipment in the upper headhouse consists of a kickback dump, receiving hopper and reciprocating feeder. That in the middle headhouse includes a crossover dump, receiving hopper and reciprocating feeder. The retarding conveyor is 588 ft. long with a capacity of 300 tons of coal per hour. It is of the chain-and-scraper type, and consists of a double strand of 24-in. pitch chain, made up of $\frac{3}{8}$-in. steel side bars with 6-in. diameter cast-iron single-flanged rollers, steel bushings and steel pins $1\frac{1}{4}$ in. in diameter. Steel flights 12 x 36 in. are spaced at intervals of 3 ft. The conveyor trough is made up of $\frac{1}{4}$-in. steel plates. In Fig. 2 is shown a cross-section through the conveyor, while Fig. 3 shows the conveyor loaded with coal.

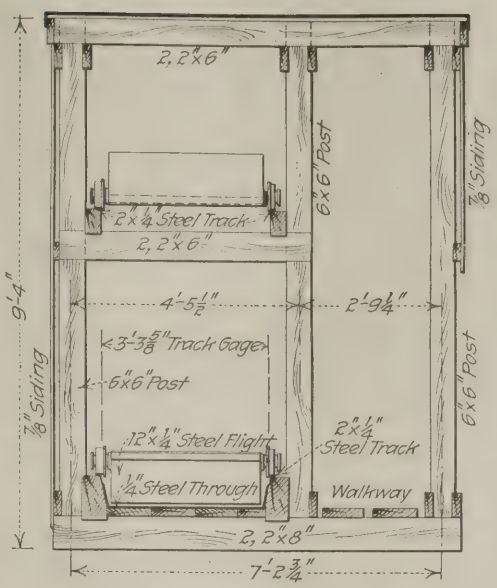


FIG. 2. CROSS-SECTION THROUGH CONVEYOR

The retarding conveyor and the feeder in the upper headhouse are driven by a 40-hp. electric motor. The feeder in the middle headhouse is driven by a 5-hp. motor.

A cross-section through the tipple proper is given in Fig. 1. Much time and attention was devoted to the design of the tipple so as to secure minimum breakage, easy and complete separation of coal and facilities for picking and cleaning. In general, the tipple equipment consists of a double set of shaking screens, picking tables and loading booms for lump and egg coal; picking table and loading chute for nut coal; a slack and run-of-mine bin; and mixing and refuse conveyors. Provision is made for loading run-of-mine coal without operating the screens by means of a valve actuated by rack and pinion placed in the trough of the retarding conveyor. From this opening run-of-mine coal is delivered by a chute to the slack and run-of-mine bin; thence to railroad cars on track No. 1. The upper shaking screen is 6 ft. wide by 21 ft. long and has a screening surface 12 ft. long for slack coal. By means of a fly valve slack coal can be either loaded direct to the slack bin or carried forward to the nut-coal chute on the lower shaking screen, thus securing the advantage of mixing slack with the nut coal. At the loading end of the nut conveyor, and running cross-wise of the tipple over the egg and lump tracks, is installed a conveyor of the drag-chain type. By means of this conveyor nut coal, or a mixture of slack and nut, can be carried over and mixed with either the egg or lump. A valve is also provided in the chute at the head of the nut conveyor so that nut coal can be loaded direct to railroad cars instead of into the mixing conveyor, as described above.

The mixing conveyor is of the drag-chain type and consists of a double strand of steel chain, with side bars 2 x $\frac{1}{2}$ in.; pins $\frac{7}{8}$ in. in diameter; and scraper bars spaced

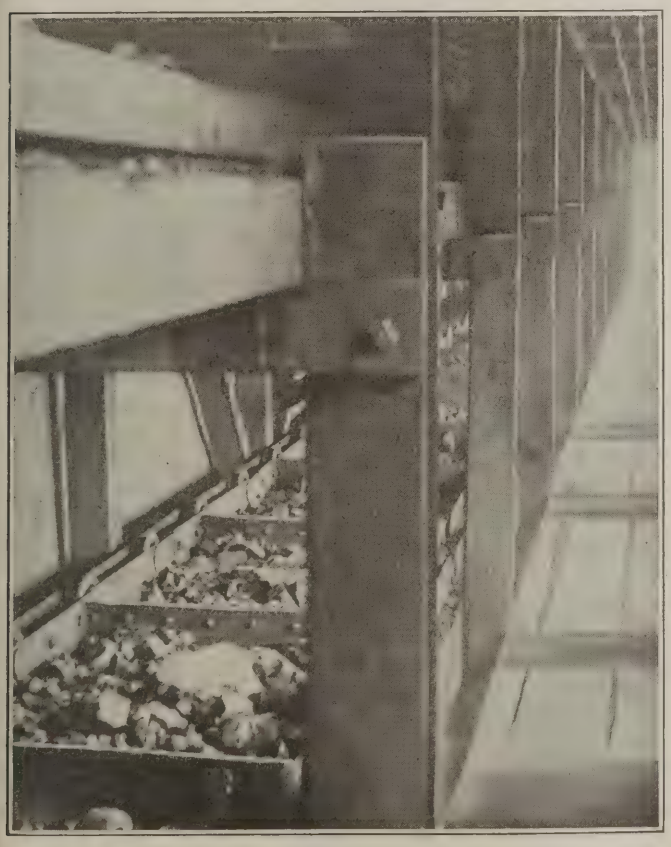

FIG. 3. VIEW OF CONVEYOR LOADED WITH COAL

FIG. 4. VIEW OF LOADING TRACKS

FIG. 5. SHAKING SCREENS (NOTE EQUAL DISTRIBUTION OF COAL

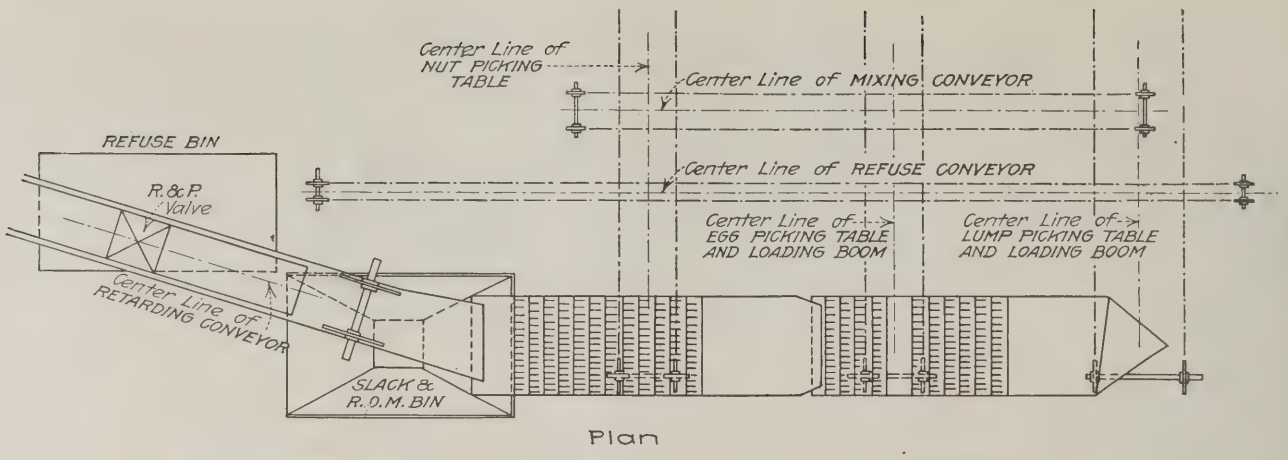

FIG. 6. PLAN, SHOWING SHAKING SCREENS AND CONVEYORS (SEE FIG. 1)

every 2 ft. The conveyor trough is built up of $\frac{3}{16}$-in. steel.

The lower shaking screen is 6 ft. wide by 23 ft. long, with a screening surface for nut coal 4 ft. long, composed of $1\frac{3}{4}$ x $1\frac{1}{2}$ x 12 in. flanged lip screen. The screen surface for egg coal is 8 ft. long, made of $3\frac{1}{2}$ x 3 x 8 in. flanged lip screen. The egg and lump coals are discharged to picking tables having a picking space 16 ft. long. The egg table is 3 ft. and the lump table 5 ft. wide. Fitted to both egg and lump tables, and forming an integral part thereof, are loading booms, each 26 ft. long, by means of which coal can be lowered into railroad cars with a minimum amount of breakage.

FIG. 7. LOADING BOOM LOADING COAL TO CAR

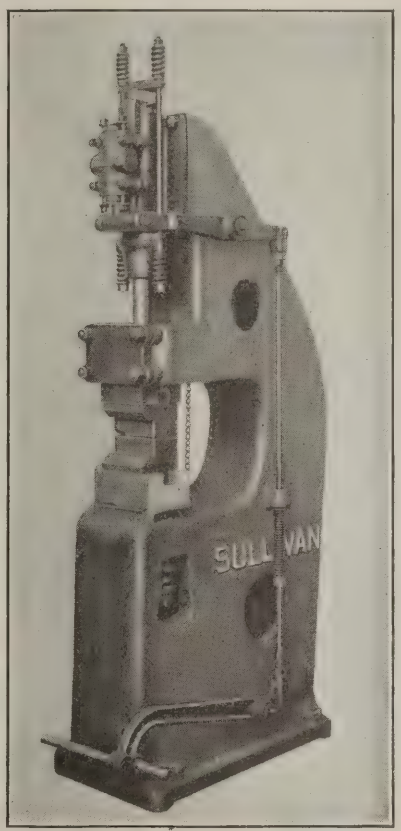
The chain for the nut conveyor, and the egg and lump picking tables, is 9 in. pitch with extended side bars 7 in. high. The steel pans are double-beaded and $\frac{1}{4}$ in. thick.

The refuse from the picking tables is thrown into a refuse conveyor. This runs under the picking tables, up an incline, and discharges into a refuse bin. From here the refuse is drawn at intervals into railroad cars.

The shaking screens and mixing and refuse conveyors are driven by a 35-hp. electric motor through a common countershaft. Friction clutches are provided so that either conveyor can be thrown out of gear if desired. Eccentric shaft for the screens is $4\frac{1}{2}$ in. in diameter. The eccentrics are of cast iron of the ball-and-socket type, while the eccentric rods are made of 6-in. channels placed back to back.

It will be apparent that although this equipment is compact and simple in every respect, yet all conditions are met to insure the production of coal and of nearly every mixture called for by the market. This installation was designed and manufactured by the Marion Machine, Foundry and Supply Co., of Scottdale, Penn. C. J. Creveling is general superintendent of the Blackwood Coal and Coke Co. in this region. Through his efforts the company has made marked progress in the Virginia coal fields.

Pittsburgh Coal Co. Sells Shares to Its Employees



For many years the Pittsburgh Coal Co. has had an association to enable employees to purchase preferred and common stock of the company at the rate of $1 per share per month. When the association closed its books on Jan. 31, 1919, it had 1817 uncompleted contracts calling for the delivery of 16,961 shares. On these contracts $589,966.41 had been paid.

The completed contracts already cover 8748 shares. Thus the number of shares either delivered or to be delivered to the employees on association contracts totals 25,709. A 100 per cent. roll of honor has been started, and 13 different departments have qualified. In these departments every employee has stock. So far not a single mine has that distinction, the honor rolls being attained only by departments at Pittsburgh, Columbus, Buffalo, New York City, Akron and Youngstown, and by the Monongahela Saw and Planing Company.

A Mechanical Blacksmith

A mechanical blacksmith, called the "Utility Hammer," has been developed by the Sullivan Machinery Co., for doing by machine work previously done by hand. It is admirably adapted for rapidly making cutter bits (both pick and chisel point), chisels, wrenches and small tools of all kinds, straps, bolts, small levers, keys and wedges; for forging, welding and straightening rods and bolts; for sharpening miners' picks and crowbars; and for many odd jobs which arise frequently around the mine.

This hammer consists of a rigid cast-iron frame, supporting the guide block, and a vertical engine. Air is admitted to the engine through a pipe connected with some source of air supply, and live air is kept in the lower end of the cylinder at all times. When the foot lever is depressed by the blacksmith, the hammer begins to strike. A single blow may be struck by this hammer or many in succession, either light or heavy as required, and at the will of the operator. The machine has a wide throat, the distance from the center of the die to the frame being 15 in., so that large work can be handled. It takes pieces up to 2 in. in thickness.

SULLIVAN "UTILITY HAMMER"

The four chief advantages of the machine are as follows:

1. *The Vertical Hammer* — The engine is to all intents and purposes the Sullivan FF-12 rock drill—a highly developed machine, the product of many years of labor and experiment. The chief feature of this drill is its vicious slugging blow at full stroke. This can be throttled down by the valve action to a light tap.

2. *The Air Drive*—With a machine of this type, air would seem to be more advantageous as a motive power than belt, chiefly because of its flexibility and ease of lubrication. With air it is a simple matter to lubricate the vertical hammer properly by means of an automatic lubricator; and the air-thrown valve gives a wider range in striking power, and a greater sensitiveness of control than can possibly be obtained with belt drive. Moreover, with air drive the exhaust can be used to blow chips, scale, etc., from the face of the die. This is highly important when cut-out dies are being used, for unless the dies are kept clean scale cuts into them and eventually leads to their being discarded.

3. *The Foot Control*—The foot lever which controls the action of the hammer has a relatively long travel, whereas the valve travel is quite short. This results in close valve control and enables the operator to govern the force of the blow of the hammer absolutely, thereby allowing great flexibility (varying from a light tap to a heavy blow). The operator can feel the action of the valve with fair precision with this long travel of the foot lever for the relatively short movement of the valve.

4. *Rapidity of Stroke*—The hammer is capable of 600 blows per minute and is therefore unexcelled for rapid work.

This machine can be equipped to operate by steam power if desired. Dimensions, weights, etc., are as follows: net weight, 1675 lb.; overall height, 6 ft. 6 in.; depth of base, 29 in.; width of base, 16½ in.; hammer cylinder, diameter, 5⅜ in.; hammer cylinder, stroke, 5¾ in.; air pressure required, 80 to 100 lb.; air consumption at 90 lb., 93 cu.ft. per minute; total striking weight, 100 lb. (Any dies can be made up from blueprints or samples.)

The development of this hammer is the result of the tremendous quantity of chain coal-cutter bits required for mining machines. The hammer is merely the vertical member of the Sullivan drill sharpening machine—the horizontal hammer being omitted because of the lack of necessity for upsetting work in the making of cutter bits.

In the Chicago shops of the builders single hammers have sharpened as many as 2000 chain machine pick-point or chisel-point bits per 10-hour day.

Self-Dumping Cages Help Illinois Mine Make High Hoisting Record

The Orient mine of the Chicago, Wilmington & Franklin Coal Co. on Mar. 6 hoisted 6777 tons of coal from a depth of 600 ft. This is believed to be a new world's record for a shaft mine hoisting one car of coal at a time. To make such a record as this two pieces of apparatus must be thoroughly reliable—the hoist and the cage. Of course, other devices such as the rope, the sheaves, the cager and, in fact, all physical equipment must "stand up" under the stress of such rapid production. The organization also must function properly. Upon the two pieces of apparatus first mentioned, however, the brunt of the stress falls.

It is interesting, therefore, to note the kind and type of hoist and cages employed at this mine. The hoist here used is a Nordberg 28 x 54-in. engine with cylindro-conical drums 7 ft. in minimum and 11 ft. in maximum diameter. The maximum rope speed is about 4500 ft. per minute.

To cage, hoist and dump three or more cars per minute from a depth of 600 ft. requires a cage of great strength and reliability. The cages employed at the Orient mine are known as Olson self-dumping cages and were built by the Eagle Iron Works of Des Moines, Iowa. Their performance on Mar. 6 last speaks well for their reliability under the stress of rapid hoisting.

THE LATEST RECIPIENT of the John Fritz medal was J. Waldo Smith, for his most distinguished service in engineering and great achievement as engineer in providing the city of New York with a supply of water. Similar service is now recognized by the more progressive coal companies, among others, as being a good business move as well as an engineering achievement. Most mining towns tend to encourage unsanitary conditions by reason of many people, comparatively, living in a limited area. The health of such communities is maintained ordinarily by attention to water supply and sewage removal.

Automatic Reclosing Circuit Breakers in Mine Service

By E. C. Raney
Columbus, Ohio

SYNOPSIS — *The increasing use of electrical distribution of energy has brought many problems of economy in transmission and operation. Automatic control of various circuits not only protects those circuits and the machinery operating thereon, but also in no small degree lessens the expense of attendance.*

DURING the past few years coal mines have made some radical changes in the method employed for obtaining and distributing direct-current power for mining machines and motors. The old isolated steam plant has largely passed out of existence, and in its place has come the central station delivering current to the individual mines over high-tension alternating-current lines.

At the mines this high-tension alternating current is converted into direct current by means of rotary con-

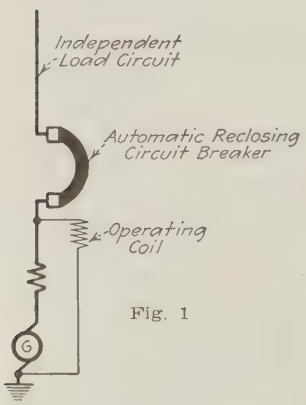


Fig. 1

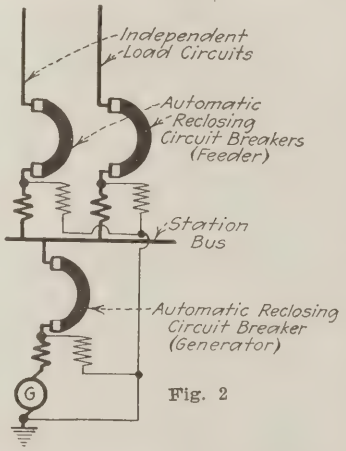

Fig. 2

FIGS. 1 AND 2. BREAKERS ON ONE AND TWO LOAD CIRCUITS

verters or motor-generators at a suitable voltage. The usual potentials for trolley use are 250 or 500 volts.

The many advantages of the central-station method of power generation and distribution are too well known to be taken up in this article. I wish, however, to enumerate two of the most important economic advantages to be gained by this arrangement, as a clear understanding of these together with a thorough knowledge of the application of the automatic reclosing circuit breaker to such installations makes possible the proper location and arrangement of equipment to obtain the best results at a minimum cost.

First, by obtaining central-station power for the mine the substation can be located near the load center. This saves a large amount of copper in the feeder lines, reduces power losses to a minimum and increases the output on account of better voltage being available at the motors.

Second, through the use of central-station power the cost of attendance at the substation can be practically eliminated, since it only requires an attendant to start the station in the morning and to shut it down at quitting time. It will be explained later in this paper how the shutting down can be accomplished automatically if so desired.

The operation of substations without an attendant has been made practical by the development of the automatic reclosing circuit breaker and other automatic

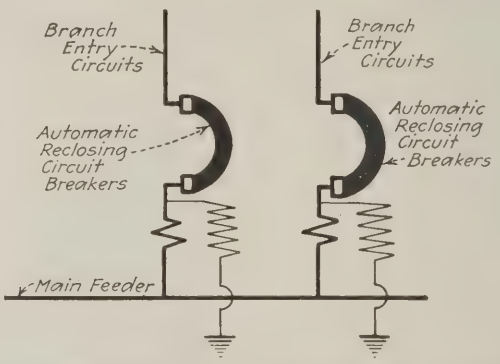

FIG. 3. BREAKERS ON INDEPENDENT CIRCUITS

protective devices. With a station properly protected by these instruments, operation without an attendant is much safer than it would be with an attendant, but with the automatic protective devices omitted. The elimination of the human element is always desirable where the same results can be obtained with certainty by automatic means.

There are four general classes of protection to which automatic reclosing circuit breakers are applied, each of these classes requiring a different arrangement of control circuits governing the breaker. These may be

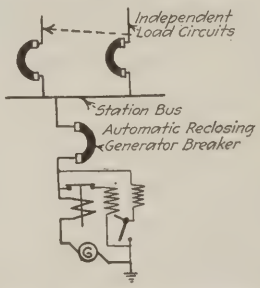

FIG. 4. AUTOMATIC BREAKER BETWEEN GENERATOR AND BUS BAR

enumerated as follows: (1) Protection of independent feeder circuits; (2) protection of generator circuits; (3) protection of feeders to a trolley that is also supplied by current from other stations; (4) the sectionalizing of circuits.

Taking up the foregoing classifications of control in their order, Figs. 1, 2 and 3 are simplified diagrams illustrating the application of automatic reclosing circuit breakers to the protection of independent feeder circuits.

Fig. 1 illustrates the most elementary case in which

a single generator is supplying a single outgoing load circuit and is protected by a plain automatic reclosing circuit breaker. Such an instrument for independent load circuits should have the following characteristics: (a) It should open in case of overload, short-circuit, or voltage failure; (b) it should remain open through a definite time interval; (c) it should reclose automatically at the expiration of the time interval provided the short-circuit has been removed; (d) it should remain open without any attempt to reclose so long as the short-circuit or overload exists.

Fig. 2 illustrates a station equipped with a single generator but having two independent load circuits. In

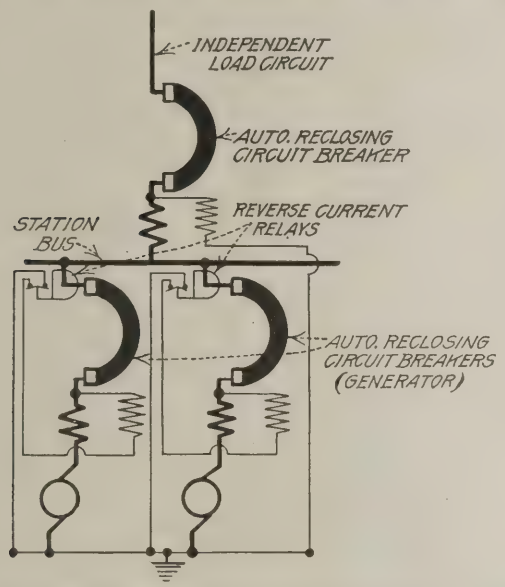

FIG. 5. TWO GENERATORS ON A COMMON BUS

this case an automatic reclosing circuit breaker should be used on each outgoing circuit so that in the event of overload or short-circuit on either section the other section will continue to supply power uninterruptedly.

Fig. 3 illustrates another application of breakers for independent feeder circuits. With this arrangement each important branch circuit is protected by an automatic breaker so that trouble on one section will not interrupt service on the remaining sections. This item is quite important in mines where much trouble is experienced on account of falling slate and other conditions which frequently cause short-circuits to occur on the various lines.

Figs. 4, 5 and 6 illustrate three typical arrangements of circuits wherein generator breakers are required between the generator and station bus. The generator breaker in its simplest arrangement has the following characteristics: (a) It should open in case of overload, reversal of current or voltage failure, and (b) it should reclose automatically at the expiration of a definite

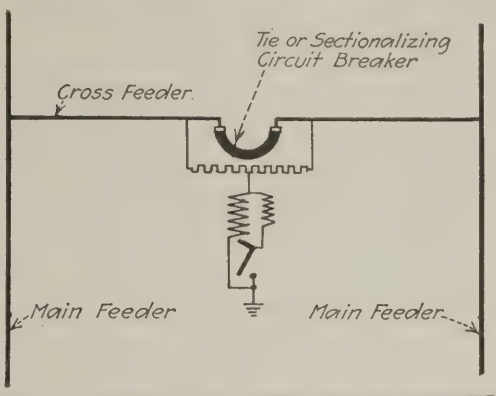

FIG. 8. TYING MAIN FEEDERS TOGETHER

time interval provided the voltage of the generator is at or above a certain predetermined value.

Fig. 4 illustrates an elementary arrangement where an automatic reclosing circuit breaker is used between the generator breaker and the busbar. Each independent load circuit is supposed to be properly protected with automatic circuit breakers.

Fig. 5 illustrates a case where two generators are operating in the same station feeding into a common bus. The outgoing load circuit is protected by an automatic circuit breaker, and each of the generator breakers is provided with overload protection and reverse current relay protection.

Fig. 6 illustrates a station where the generating equipment is protected by an automatic breaker, the operating coil of which is carried through contacts controlled by the alternating-current switch, through thermostats on the transformer and bearings, and through an overspeed device on the rotary converter shaft.

In this case a no-voltage relay is located just above the alternating-current handle so that in the event of the opening of any of the protective devices mentioned the armature of the no-voltage coil will be released and trip open the alternating-current switch. This action opens the direct-current circuit breaker permanently at the same time that the alternating-current switch is

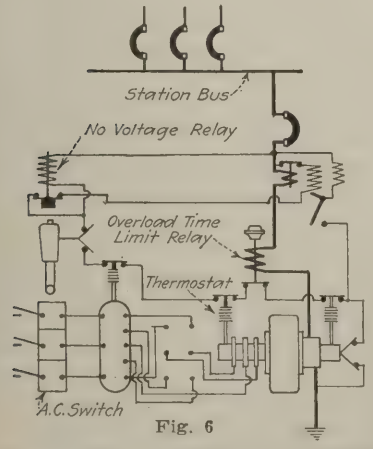

Fig. 6

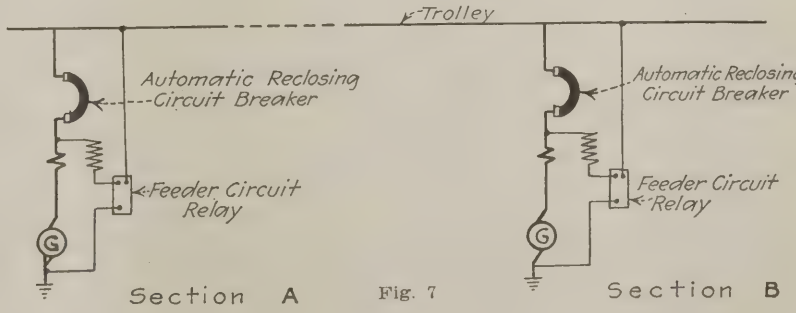

Fig. 7

FIG. 6. AUTOMATIC BREAKERS USED WITH OTHER PROTECTIVE DEVICES—FIG. 7. BREAKERS AT WIDELY SEPARATED SUBSTATIONS

opened. The generator will thus be completely protected in the event of overspeed, hot bearings, a hot transformer or an excessive overload on the alternating-current circuit. The generator breaker, however, will open and reclose automatically in case of a direct-current overload.

Any combination of the foregoing protective features may be used, or this scheme may be extended so as to provide protection against almost any conceivable contingency which would make it desirable to shut the station down. For instance, in some plants where the load demand continues until midnight or after, a time clock is provided which opens the circuit of the no-voltage relay, thus shutting down the station automatically at a predetermined hour without the necessity of an attendant being present.

Owing to the high power losses in transmitting low-voltage direct current it is not advisable to transmit current for power purposes more than one mile at 250 volts or more than four miles at 500 volts. Whenever these distances are exceeded it results either in excessive loss of power or it means that an excessive amount of copper must be used in the trolley circuits.

Where central-station current is available it is usually more economical to use smaller units in motor-generator stations and locate them at intervals of 1½ to 2 miles, as illustrated in Fig. 7. Where this arrangement is employed it is necessary to use a feeder-circuit relay with each automatic reclosing circuit breaker. The object of the feeder-circuit relay is to govern the reclosing of the breaker so that in case the trolley voltage is below a certain value opposite a given station, such as *B* while station *A* is still feeding the circuit, the breaker at station *B* will remain open until the voltage

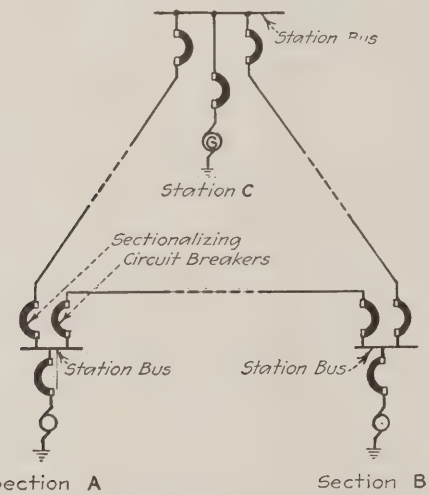

FIG. 9. TYING THREE STATIONS TOGETHER

has reached such a value opposite station *B* that the breaker there will not open immediately after reclosing.

In some instances considerable economy in transmission is effected by tying two main feeders together at some distant point in the mine by cross feeders, as illustrated in Fig. 8.

There is a serious objection, however, to this arrangement unless the cross feeder is protected by some automatic means, so that should a short-circuit occur on one of the main feeders the other will be disconnected during the time that the short-circuit remains effective, and will be reconnected automatically when conditions again have become normal.

In some cases three stations are tied together, feeding into a common network of trolleys and machine circuits, as illustrated in Fig. 9. This makes an ideal arrangement so far as economy of copper is concerned.

With this arrangement the generator at each station should be protected with an automatic reclosing circuit breaker between the generator and bus, and each outgoing feeder should be provided with a sectionalizing circuit breaker. When this plan is followed a short-cir-

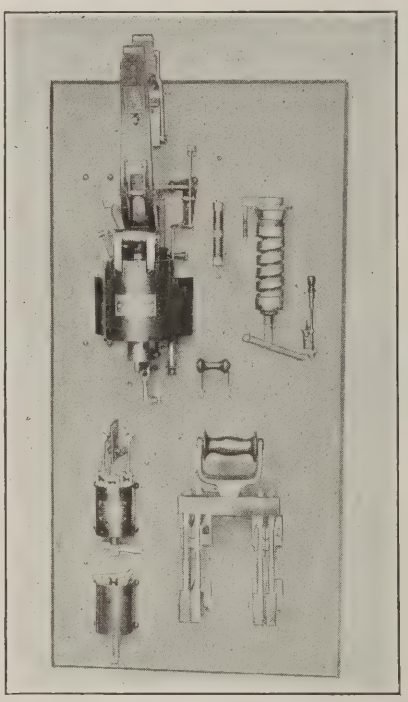

FIG. 10. SWITCHBOARD PANEL WITH AUTOMATIC RECLOSING CIRCUIT BREAKER

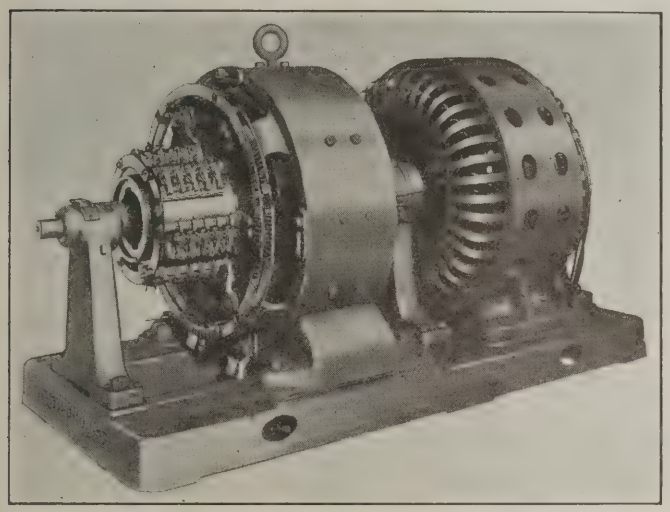
cuit between stations *A* and *C* will open the two breakers feeding this section, but operations on the remainder of the system will not be disturbed. Furthermore, with this arrangement it is possible to operate all stations *A*, *B* and *C* simultaneously when the load is heavy, while one or two stations may be shut down during the period when the load is light. The entire system will then be fed from one station.



By the use of sectionalizing breakers, when station *A* is supplying the entire system with stations *B* and *C* shut down, current will be fed through the two breakers at station *B* and through the two at station *C*. When feeding in this manner the current in one breaker in each station will be fed in a reverse direction to what it is when all stations are running. This necessitates the use of automatic sectionalizing breakers which will operate equally well with current supplied from either direction. The application of sectionalizing breakers in this manner in a recent development and is one which is of considerable importance in the proper operation of systems of this character.

SOME IMPORTANT American business enterprises in considering plans for expanding their American activities into world-wide activities are concerned over the matter of an American merchant marine. Several of our large corporations, including coal producers, have found it of considerable advantage to own and operate their own vessels. The organization of ship lines by exporting interests and their operation by managements controlled by the exporters would possibly so tie together the commercial and the transportation interests as to make them pay.

New Motor-Generator for Mines

There are periods during the day when the electrical load of a coal mine is light, and then in an instant the demand for power may jump to several times the average. Such conditions occur with the starting or stopping of hoists and locomotives, and demand extra-good peak-load performance of the generating apparatus. This is especially true as regards synchronous motor-generator sets, for the generators are denied the relief afforded by the fall in speed of an engine-driven set, since they run at unvarying speed.

A new synchronous motor-generator set which embodies the continuous power-factor correction common to such sets with high overload and "peak" capacity has recently been put on the market by the Westinghouse Electric and Manufacturing Co. It consists of a type G three-phase, 60-cycle, synchronous motor driving a type SK, 275-volt compound generator. The machine has three bearings, the pedestals and field frames being mounted on a common bedplate. The full-load rating is based on continuous capacity with 35 deg. C. rise on the

EFFICIENT MOTOR-GENERATOR FOR MINE SUBSTATIONS

generator, 45 deg. C. on motor armature and 50 deg. C. rise on motor field, with 80 per cent. power factor. After a two hours' run at 50 per cent. overload, the generator and the motor temperature rise will not exceed 55 deg. C. On test, commutation was satisfactory at 250 per cent. load. The compound field is adjusted to give 10 per cent. increase in voltage from no load to full load.

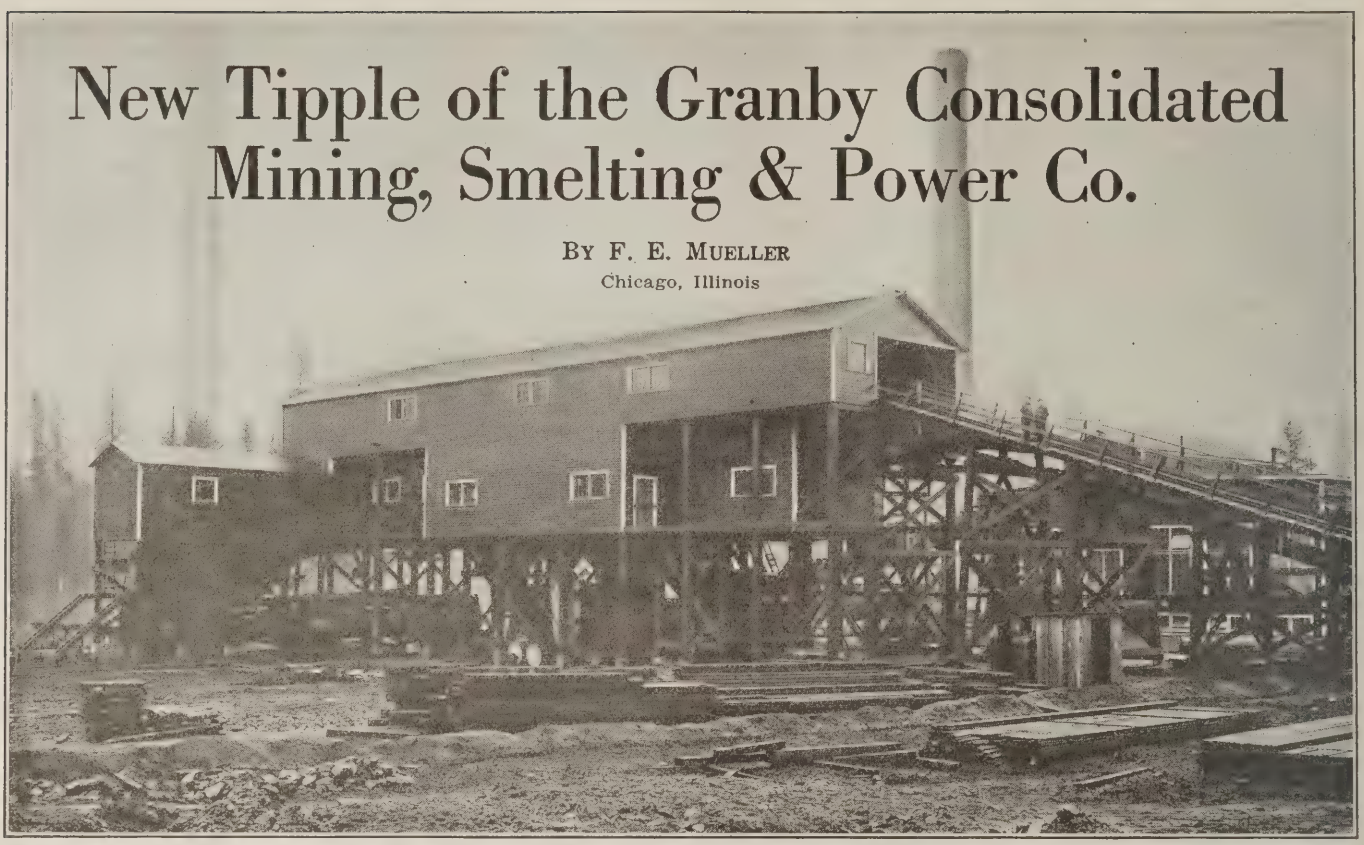
In addition to commutating poles on the generator, there is a compensating winding placed in slots in the faces of the main poles. This considerably improves the efficiency and gives extremely good commutating characteristics. This winding consists of but one continuous coil per pole. Each coil is form-wound to exact dimensions, and is put into open slots in the pole faces, where it is held by wedges. This construction gives one joint per pole instead of two joints per conductor, as has been the custom in the past, where jumpers were used between bars. No difficulty is found in removing and replacing coils.

The motor is a six-pole, revolving-field machine, provided with squirrel-cage damper winding in the pole faces. This permits of starting the set from the alternating-current side and also insures its stability under sudden variation of load. The field may be overexcited to draw "leading" reactive current from the line, thus compensating for the "lagging" current of induction motors. This helps the voltage regulation, especially where a long transmission line is used. A voltage regulator may be employed, which will hold the alternating voltage constant within the range of the set.

The performance of this set is as follows: Efficiency at one-half load, 81.4 per cent.; three-quarter load, 85 per cent.; full load, 86.5 per cent.; one and a half load, 88 per cent.

Carbonization of Illinois Coals in Inclined Gas Retorts

Under the conditions existing in the winter of 1917-18 it was desirable to use as much as possible of the coal mined locally in order that long railroad hauls might be avoided and that the crowded transportation systems be lightened. Gas manufacturers of the middle west saw the importance of a local supply of coal because of the increasing difficulty of obtaining supplies of eastern gas coal, and many companies considered the possibility of using Illinois coal for at least part of their requirements. A high yield of gas of good quality is the result sought in the manufacture of illuminating gas in retorts. Coke, tar and ammonia are byproducts that are recovered in order to increase the economy of process. Coke is the chief of these byproducts, and its quality should be given consideration in selecting and carbonizing the coal.



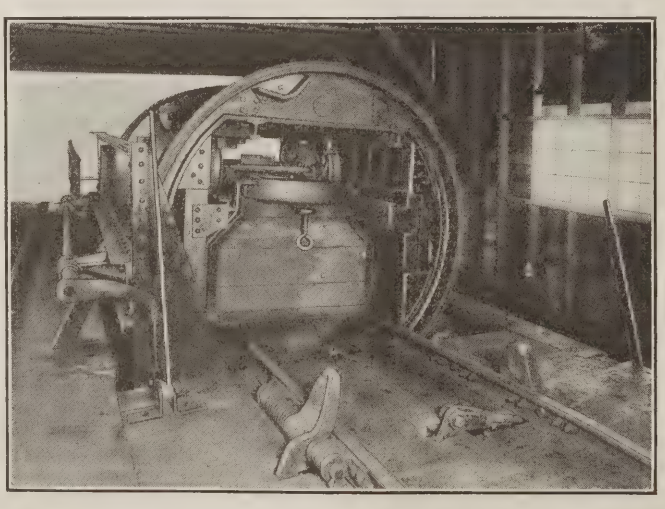
Tests were undertaken in an endeavor to obtain further information regarding the use of Illinois coals in gas retorts. These tests were made by the Bureau of Mines in coöperation with the Illinois State Geological Survey and the Engineering Experiment Station of the University of Illinois. It was desired to ascertain how the quality of the coke obtained was affected by mixing Illinois with eastern gas coal. Where Illinois coals have been used for gas making, the usual practice has been to charge a part of the retorts with Illinois coal alone and the rest with an eastern gas coal.

The coke from the two coals was sold separately; that from the eastern coals was sold for domestic purposes while that from the Illinois coal was consumed at the plant. Another object of the tests was to permit the use of better operating conditions than are possible when the two coals are coked separately. These tests are described in Coöperative Coal Mining Series—Bulletin No. 20—under the title of "Carbonization of Illinois Coals in Inclined Gas Retorts," by F. K. Ovitz.

In this bulletin the following summary of results and conclusions is given: Illinois coal mixed with Kentucky coal before charging yields better coke than Illinois coal alone. If all the retorts are charged with the same mixture, uniform operating conditions can be maintained to insure proper carbonization of all the charges. Coke from Illinois coal alone contained more ash and had more tendency to form clinker than coke from a mixture of Illinois and Kentucky coals. The yield of coke from mixtures was larger than from Illinois coals alone, and increased as the percentage of Kentucky coal was increased. The amount of breeze in the coke made from unmixed Illinois coal was greater than in coke from mixtures. Mixtures gave higher gas yields and consequently enabled greater production of gas with a given equipment than could be obtained from Illinois coal alone.

New Tipple of the Granby Consolidated Mining, Smelting & Power Co.

By F. E. Mueller
Chicago, Illinois



FROM time to time articles and photographs have been published showing coal measures and giving general data covering the new mining plant of the Granby Consolidated Mining, Smelting and Power Co., Ltd., at Cassidy Siding, near Nanaimo, on Vancouver Island. It is not the purpose here to go into details concerning the mine development or the surface plant. It is sufficient to state that the arrangement of the camp, housing facilities for the comfort of the employees, the shops, bathhouse and boiler equipment are second to none in the west, the entire arrangement lending itself readily to the ultimate development of this property.

The engineers entrusted to the Roberts & Schaefer Co., of Chicago, the development of the tipple. In view of the agitation against anything other than a solid body car, and consequently the use of rotary dumps, and also the careful consideration that must be given to the preparation of coal by picking or washing, a description of the general arrangement of this plant should prove of interest.

The general layout of mine car tracks, tipple and proposed washery, together with the location of slope with respect to the railroad tracks, is shown in one of the illustrations. It will be noticed that sufficient room has been provided for the storage of loaded cars pulled out of the slope, the loads being permitted, after passing over the knuckle to drift down grade at ground level to the loaded trip feeders, which push the cars one at a time onto the loaded car-haul.

Another illustration shows the mine car that is in use at this property. The loaded car-haul and tipple are of sufficient capacity to handle three cars per minute. The headpiece of this article shows the completed tipple, the Marcus house, and at the extreme left the loading boom shed.

After the cars have reached the top of the loaded car-haul they drift over a platform scale and then on toward the rotary dump, which is also illustrated. This rotary dump is of the Head-Wrightson type—the Canadian rights of which, together with those of the Marcus patent picking table screen, have been entrusted to the care of the Roberts & Schaefer Co. since the outbreak of the war. This type of rotary dump is not new to coal operators of western Canada, as it has been in successful use at a number of mines; but probably nowhere has it operated with a car of such large capacity as at Cassidy Siding.

VIEW OF THE ROTARY DUMP AND MINE CAR

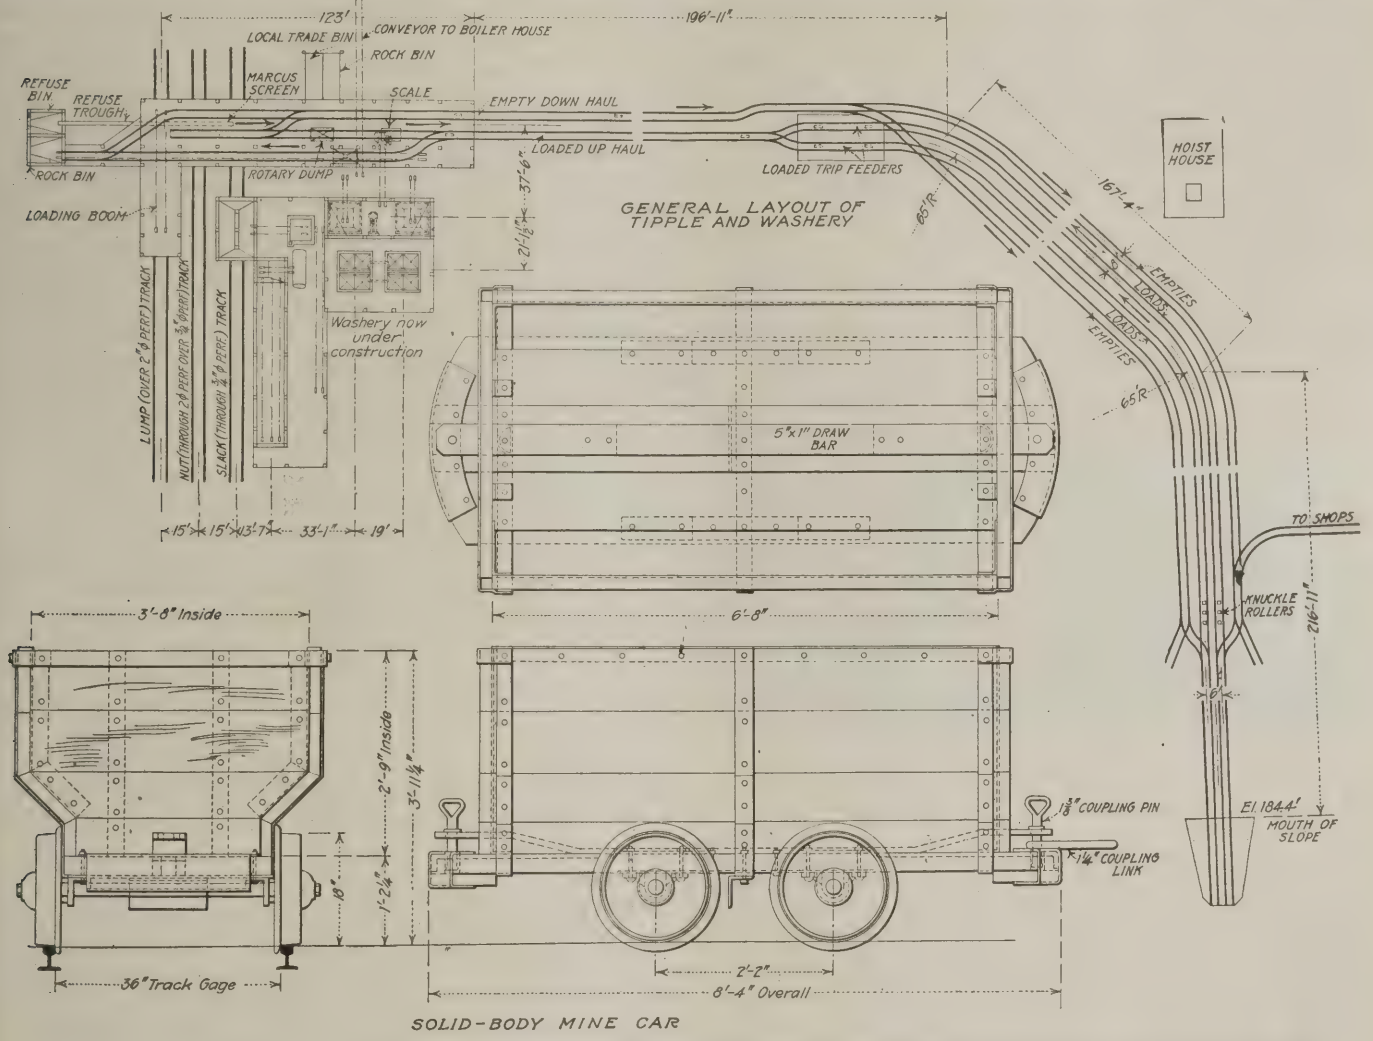
Another feature of interest in connection with this dump is that it is provided with Mining Safety Device Co.'s feeders so that the feed of cars to the dump is automatically controlled, thereby avoiding delay and liability to wrecks which might occur if the cars were not regulated into the dump. All parts of the car feeders

and revolving dump are of substantial construction and are easily accessible in case repairs are necessary.

The empty cars standing in the revolving dump are started forward by the load entering, the arrangement of tipple tracks being such that empty cars run by gravity from the rotary dump to the kickback and thence to the empty track. From here they are lowered by means of a car-haul to the ground level, whence they can drift on to either of the empty storage tracks for making up trips preparatory to lowering into the slope.

Provision has been made for handling mine cars loaded with rock by taking them off at the head of the loaded car-haul and passing them over a rock track, which leads to a rock bin. This, however, is for future requirements, at which time a duplicate revolving dump will be placed over the rock bin. The empty rock cars will drift by gravity back to the empty mine car track of the tipple and thence on over the down haul to the empty yard.

For the early development of the mine the rock will be handled over the rotary coal dump. A bypass is provided in the chutes leading from the dump so that the rock can be diverted into a temporary rock bin from which it is disposed of by means of wagons. Provision is also made in connection with the rotary dump and chutes leading therefrom to handle local-trade (or house) coal.



The coal from the rotary dump is delivered into a receiving hopper from which it is mechanically fed onto a Marcus horizontal screen 5 ft. wide, the upper deck of which is provided with perforated plate for producing lump, nut and slack coals on three tracks, or combinations of these sizes as may be desired.

Provision is also made in connection with the Marcus screen for diverting the nut and slack coals to a conveyor which delivers this mixture to the elevator of a washery which is now being installed, or the slack from the tipple can be diverted to the conveyor leading to the boiler house.

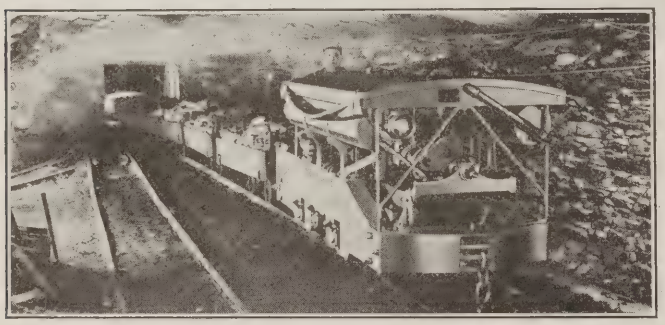
Pickings from the table are carried forward in a pickings trough which shakes with and is part of the screen proper. These pickings are delivered to a refuse bin built in conjunction with the rock bin. Provision is also made in the tipple for delivering bone coal to a crusher from which it is conveyed into the boiler house.

Ample facilities are provided in connection with the screen for thoroughly picking the lump coal. After passing over the lump perforations this is delivered without breakage onto an apron conveyor type of loading boom which lowers it into railroad cars.

With the arrangements provided for handling mine cars and the facilities for preparing and handling the finished coal products, the preparation here given should prove one that will permit of low-cost output. When the washery is built this mine will load a product onto railroad cars that will be among the best of the island coals.

GENERAL LAYOUT OF TRACKS, TIPPLE AND PROPOSED WASHERY, AND DETAILS OF SOLID-BODY MINE CAR IN USE AT THE PLANT

The Gasoline Locomotive Underground



By Paul Teas
Cleveland, Ohio

The old mine mule has had his day, not alone in outdoor work but underground as well. Mine owners long ago accepted the gasoline haulage unit as a valuable investment for outside haulage, but many have been slow in discovering that its usefulness reaches underground also. The facts are that nearly all of the good qualities of the locomotive in open-air work apply equally within the mine. Among these are the following:

1. Ability to haul longer trains and to move a greater tonnage per hour than would be possible with all the animals that could be put on the job. A marked reduction in the per-ton cost of getting out the coal naturally follows.

2. Simplicity of construction and ease of operation make it possible to man the outfit with comparatively unskilled labor.

3. Low operating cost. Fuel consumption runs usually from 7 to 15 gal. of gasoline per day, depending, of course, on the tonnage handled, distance traveled and grades encountered; also, to a degree, on the quality

GASOLINE MOTOR OPERATING UNDERGROUND

of the fuel. Two men handle the outfit—one motorman and one brakeman.

Making a liberal allowance for fuel, lubrication, wages, and interest and depreciation, the operating cost of the mechanical unit, in proportion to what it does, drops far below that of animal haulage. Furthermore, the locomotive is always ready for service, works winter and summer alike, and requires little or no care when not running.

Makers of gasoline locomotives who have studied underground haulage assert that success depends largely upon the proper adjustment of the carburetor—to secure a "lean" mixture of gasoline vapor and prevent the production of carbon monoxide gas—and upon a fair condition of ventilation within the mine.

The average operator, checking up conditions at his own mine, is not likely to encounter any serious obstacle to the operation of a locomotive to the limits of his trackage. In this connection the experience of some prominent companies are interesting.

The Central Fairmont Coal Co., Clarksburg, W. Va., with a drift mine running back about 5760 ft., operates gasoline locomotives with entire success. This mine is ventilated with only one fan, and the locomotives have to pull against a stiff grade. This makes a strong case in favor of the locomotive, since the tendency to throw off heavy fumes naturally would be greater when pulling against heavy resistance than when running on the level or down grade. The owners consider this as convincing evidence that underground gasoline locomotive haulage is a particular success in this instance.

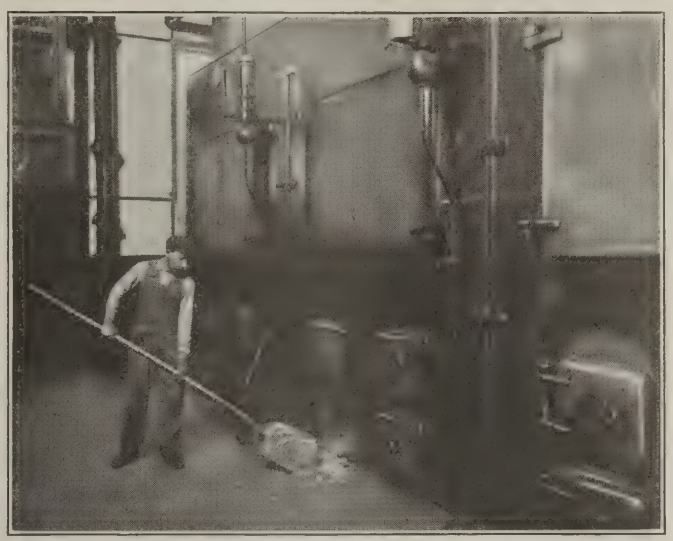
Another drift operation near Clarksburg also reports good results from a gasoline locomotive under similar conditions. The Francois Coal and Coke Co. operates about 500 ft. from the mine entrance and ventilates with one shaft. This company has used gasoline haulage for some years and is well pleased with the results secured.

At Reynoldsville, W. Va., the Hutchinson Coal Co. has placed its underground haulage upon gasoline locomotives with good results. Over in the Keystone State other concerns have shared this experience, among them the W. A. Stone Fuel Co., at Pt. Merion, and the Irwin Gas Coal Co., of Greensburg. Both firms state from experience that the gasoline locomotive when given a fair chance will work as well "down below" as in the open.

Supporting evidence comes from other mining fields. The American Gypsum Co., for example, had to "sell" the idea of gasoline haulage to the state inspector before he would sanction such an installation at the company's mine at Akron, N. Y. The haul here is approximately one-half mile underground. Ventilation is had through an airshaft about 3700 ft. back from the main shaft. The roof is quite low, and the locomotive pulls against a stiff grade under load. Not until the inspector had made personal investigation would he "O. K." the purchase of a gasoline outfit. Riding directly back of the locomotive—a Plymouth—he gave it a thorough trying-out. His report was conclusive—"combustion and air circulation thoroughly satisfactory." The Gypsum company has since purchased a second locomotive of the same kind.

The McKinney Steel Co. has several gasoline locomotives at work in its "gopher" mines at Virginia, Minn. These work back as far as 1000 ft. from the opening. The "85" Mining Co., operating a gold mine at Lordsburg, N. M., and the Southern California Edison Co., at Inyokern, Cal., both have reported good performance by gasoline locomotives underground. Ventilation in the former case is through a single air shaft, and the haulage zone extends back 800 ft. from the mine entrance. The Edison company is putting through a hydro-electric project that includes the driving of two tunnels. The haulage unit in this instance operates about a mile underground. Ventilation is provided through air pumped through pipes to the face of the work.

A reliable locomotive is cheaper in first cost than enough mules to do the same work; it will cost less to operate and keep up. It may be installed without making any important changes in tracks or other established equipment. Such a machine will start at a turn of the crank, will go nearly everywhere quickly and with big loads. When it stops, practically all the expense connected with it stops. These are the salient considerations in favor of gasoline locomotive haulage.



Only one mine in Ohio is operated by longwall, that of the La Belle Iron Works at Steubenville. The working face at the Rail and River mine in Belmont County, Ohio, is situated on an average 4¾ miles away from the entrance. The general trend in the Ohio coal field is a dip of about 27 ft. in the mile (or about a half of one per cent.) toward the southeast.

Money Saved by Use of Steam Jet Ash Conveyor

By Guy S. Hamilton
Chicago, Ill.

The Canada West Coal Co., Ltd., of Tabor, Alberta, has five 150-hp. boilers and one 500-hp. boiler installed in its boiler plant. The coal used is a fine dirty slack which has been stored on the open prairie. Owing to the inclusion of mining machine dirt, this contains about 25 per cent. of ash.

This percentage of ash is not greater than that used in many other coal-mine boiler plants, and the ash-handling problem encountered is paralleled by that of many other mines. How could the daily accumulation of ashes be quickly and economically conveyed from the boiler room to the disposal station some 250 ft. away?

INSTALLATION OF STEAM JET CONVEYOR RESULTED IN LARGE SAVING IN MANPOWER

The Canada West company was employing two ash wheelers whose sole duty was to wheel the ashes from the boilers to a dump wagon outside. Here the ashes were reshoveled into the wagon and the teamster hauled them to the dump pile or disposal station. Three men and a horse were kept constantly employed at this work. They were not used for any other purpose.

The officials of the mine felt that the scarcity of labor warranted the use of the men available at some more productive labor, and accordingly quietly cast about for some sort of mechanical equipment that would take the place of the ash handler. They finally decided to install the steam jet conveyor as a means of ash handling.

About a month ago J. R. Howard, the general manager, wrote to the manufacturers—the American Steam Conveyor Corporation, Chicago—concerning the economies effected by the use of this equipment, setting forth the following figures:

COST OF ASH DISPOSAL PREVIOUS TO INSTALLATION OF ASH CONVEYOR, PER 24-HOUR DAY	
2 Ash wheelers @ $5.44	$10.88
1 Teamster @ $4.08	4.08
1 Horse and feed @ $1.50	1.50
Total	$16.46
COST OF ASH DISPOSAL AFTER INSTALLATION OF CONVEYOR	
1 Laborer, 9 hr.	$4.08
Saving per 24-hr. day	$12.38

It will be noticed that no charge is here made for steam, but the laborer does not spend his entire time handling ashes. Between fire cleanings he acts as assistant fireman and boiler-room helper.

The conveyor installed in the plant consists of a line of pipe into which the ashes are fed and through which they are carried to a discharge point by current action. Thus this is not a mechanical conveyor. Nothing moves but the ashes and the current of air and steam. This current is created by the action of a jet of high-velocity steam in the direction of the travel of the ashes. This steam discharge tends to create a vacuum behind it, which in turn creates a current of air through the air intake in the line.

Ash intakes are located conveniently in front of the boiler ash pit door so that the firemen can rake the ashes into them with the least effort. The powerful suction pulls the ashes through the system toward the "steam unit fitting," or that point where the steam is introduced into the system. Here the force of the steam itself ejects the ashes through the remaining or "discharge line" of the system. All the ashes from a cleaning can be handled in about 7 min. The grade of the conveyor pipe line rises about 8 per cent. for 200 ft., then 45 per cent. for about 40 ft., discharging onto an open pile.

The upkeep of the system has been relatively small—less than 1 per cent. of the first cost of the equipment during the year it has been in service. During the 300 working days of the year this conveyer has saved for the Canada West Coal Co. a sum amounting to $3714, more by half than the first cost of the system. And every day it is paying a handsome percentage on the original investment.

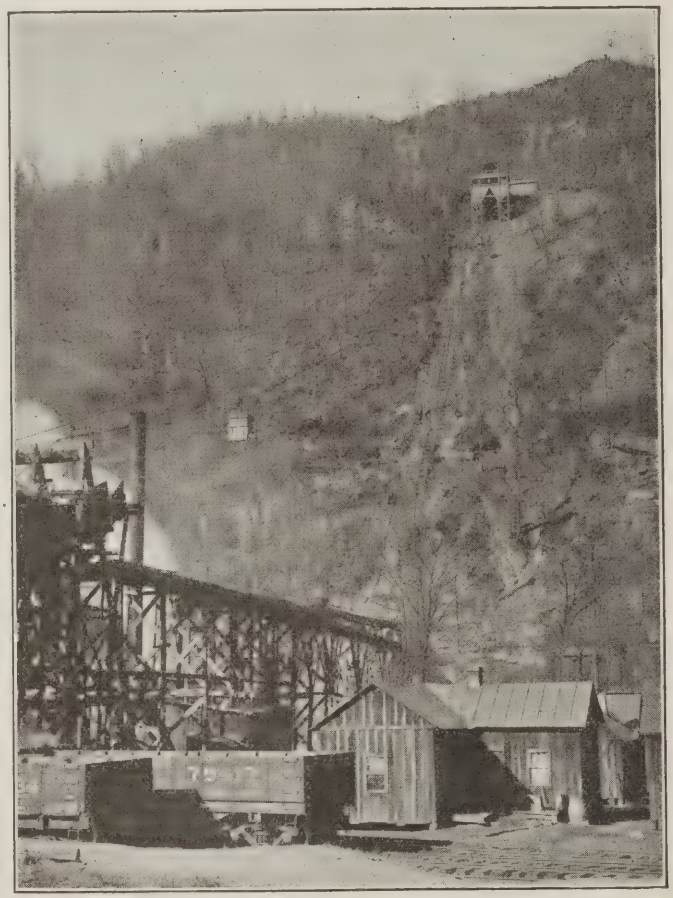
The steam-jet ash conveyor has intrinsic merits of which saving money is but one. Boiler-room cleanliness, absence of dissatisfied labor, convenience of operation, are considerations that make it desirable.

Illinois Coals Supplant Eastern Coke in Gas Manufacture

Certain Illinois coals instead of eastern coke can be used for the manufacture of water gas and at a considerably decreased cost, according to experiments that have been made in the city gas plant at Streator, Ill. This means the utilization of nearby coals at water-gas plants in the central states instead of having to depend upon the coke from eastern coals that have to be transported some distance.

Last winter Governor Lowden of Illinois appointed a state technical committee on gas, byproducts and public utilities, and through the committee a coöperative experimental program on gas manufacture was outlined by the Illinois Geological Survey, the University of Illinois, the Illinois Gas Association and the Bureau of Mines, Department of the Interior. Engineers from the Bureau of Mines and the State Geological Survey obtained permission to make their experiments with the Streator gas plant, which supplies gas for the entire city of Streator. In these experiments the engineers were able to obtain the same capacity of the plant when using Illinois coal as formerly was obtained with eastern coke and at probably a decreased cost.

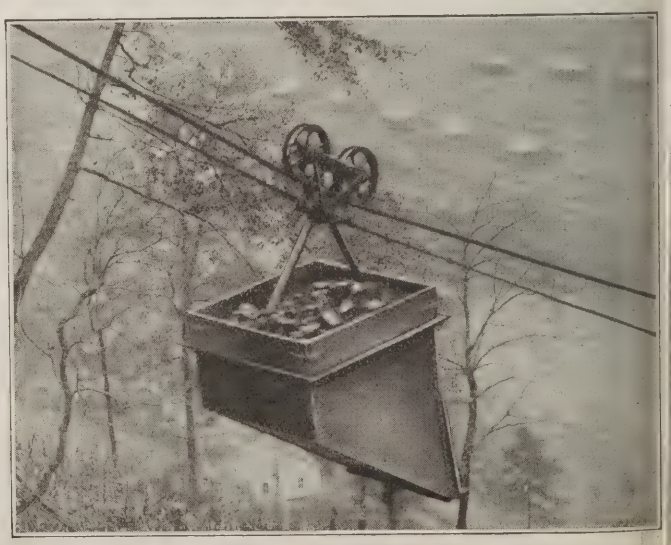
Coal Transportation by Aerial Tramway



By F. W. Grice
St. Louis, Mo.

During the last few years the aërial wire rope tramway has played an important part in the development of the coal-mining industry. The wartime need for more coal created a demand for a simple and efficient method of transportation from mine to tipple, a method free from the usual delays and interruptions, and one that could be depended upon to perform its work day in and day out regardless of weather conditions.

The adoption of the aërial tramway, particularly in the mountainous sections and where streams had to be crossed, has proved satisfactory and has resulted in a considerable reduction in operating costs. In a number of instances inclines have been discarded and aërial tramways installed with good results. The number of attendants has been reduced, a higher capacity developed, and delays in operation practically eliminated.

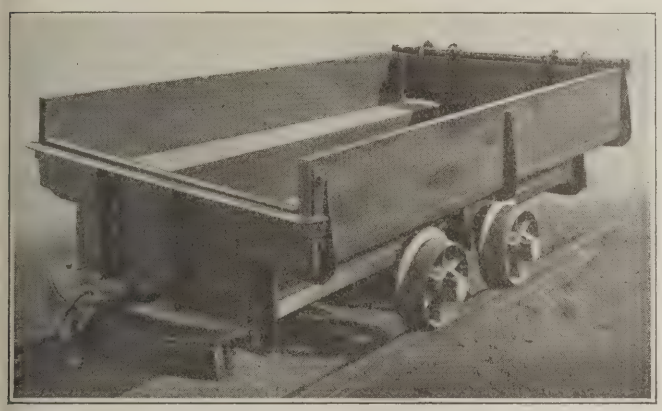


An example of an installation of this kind may be found at the plant of the Rex Coal Co., of Kitts, Ky. The mine of this company is located near the top of a steep mountain at the foot of which is a small river. The railroad and tipple are on opposite sides of this stream. Formerly an incline was used to bring the coal down the mountain side. The track thence led across a trestle to the tipple. When the need for greater capacity and efficiency arose with the outbreak of the war, the installation of an aërial wire rope tramway was decided upon. This installation was completed in the latter part of 1917 and has been in successful operation ever since. With the completion of the tramway the incline was abandoned.

This tramway is of the gravity, two-bucket or jig-back type, installed in a single span without intermediate supports. As the name implies, it consists of two buckets operating back and forth upon separate parallel track cables. These buckets are so spaced that when one is at the loading station at one extremity of the line the other is at the opposite extremity at the discharge station. They are controlled from the loading station by means of a small endless haulage rope. The coal is brought out of the mine in cars and dumped into a 50-ton bin at the loading station. One man loads the buckets and controls the entire operation of the line. At the tipple or discharge end the buckets dump the coal automatically into a chute leading to the shaker screens. Maintenance on this equipment has been low, the operation, adjustment and oiling being taken care of by the one attendant. Oiling of the track cables, over which the buckets run, is accomplished automatically by means of oiling devices mounted on the buckets themselves.

Another application of this method of transportation is at the mines of the White Star Coal Co., White Star, Ky., where two aërial tramways of the two-bucket type have been installed. The purchasers state that they

TYPICAL EXAMPLES OF AËRIAL TRAMWAY INSTALLATIONS AT KENTUCKY COAL MINES



have been operating these tramways for over a year, have never experienced trouble of any kind with them and consider them superior to the incline. Inasmuch as this firm also operates two inclines, this statement carries considerable weight.

Details concerning the operation of these tramways may be secured by writing to H. H. Bennet, secretary and treasurer of the Rex Coal Co., Kitts, Ky., to W. L. Hammond, general manager of the White Star Coal Co., White Star, Ky., or to the Broderick & Bascom Rope Co., St. Louis, Mo., which furnished the installations.

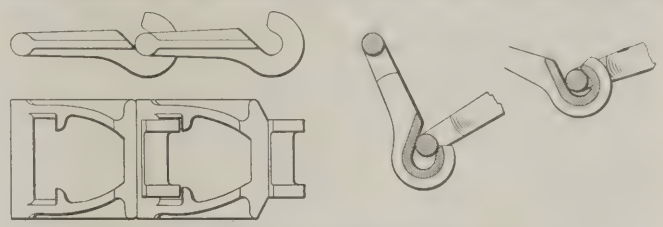
New Type of Mine Car

The Anniston Steel Co., of Anniston, Ala., has recently produced a type of mine car that embodies several novel features in design. The specifications for this car are as follows: Capacity, 2000 lb.; inside length, 7 ft.; inside height, 18½ in.; height above rail, 30 in.; width at top, 4 ft.; diameter of wheels, 12 in.; track gage, 36 in.; wheel base, 20 inches.

All body irons are made of structural shapes formed to exact dimensions. Stiffening bars are made from Z-bar, 1¾ x 2 x 1½ in., all riveted to the body binders and bolted at each end to the bumper. This holds the

MINE CAR THAT POSSESSES MANY NEW FEATURES

car in perfect alignment. The drawbars are made from 2 x 3½ x ⅜-in. tees. Attached to the ends of this bar are electric cast steel drawbar hooks and eyes, with electric forged steel hitchings.



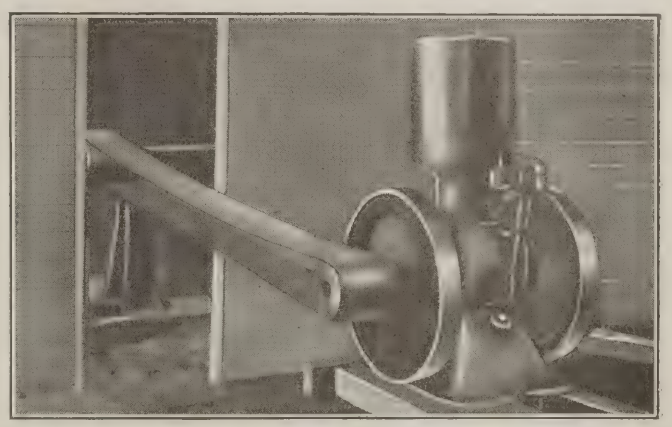
The assembly of the truck and its attachment to the bottom of the car is either by 3 x 3 x ⅜-in. angles or by 10-in. 15-lb. channels, as required. In either case these are riveted to the body irons as well as the drawbar and stiffening Z-bar. The wheels are provided with a ⅜-in. pipe plug for oiling purposes. The axle housings are bolted through the channels or angles, passing through the entire bottoms and inside washer plates.

The axles are made from sufficiently high carbon steel to permit turning and hardening to exact dimensions that portion used for a bearing surface. The wheels are of electric cast steel, cast in steel chillers to insure their being perfectly concentric, thus facilitating the machining and boring. These wheels are greased or oiled before assembling and are bored to a tolerance of 0.002 in. for application of the Hyatt shock absorber roller bearing. The housings are also electric steel castings, designed especially to prevent dust and other disintegrating substances from entering the bearings and are well packed with felt for this purpose. The oak used is the best grade found on the market.

A New Sprocket Chain

A new type of sprocket chain link has been invented by J. C. Law, of Carbondale, Penn. This chain is designed to obviate the shortcomings of the ordinary link belt, particularly in respect to the weak portion of the link where its side is notched to permit the attachment of one link to another.

A lug projects inward from either side of the link to bind against the hook of the next link and thus to pre-



DETAILS OF SPROCKET CHAIN LINK

vent the two from becoming detached. In connecting links together they may be joined by simply placing them at right angles and slipping the end bar of one into the hook of the next. Adjacent links will not become detached in any position they normally assume.

This chain link is designed to work upon ordinary sprockets. The two chief advantages sought are greater ease of connection, link to link, and greater strength. It would appear that both of these objects had been accomplished. This type of chain will be placed upon the market in a few months.

Driving Fans by Means of Internal-Combustion Engines

Many medium-sized coal and metal mine owners have been installing gasoline and kerosene engines lately for operating their ventilating fans and blowers. As the air shaft is sometimes quite a distance from the main power plant, it has been found economical to operate the fans by internal-combustion engines. The cost of

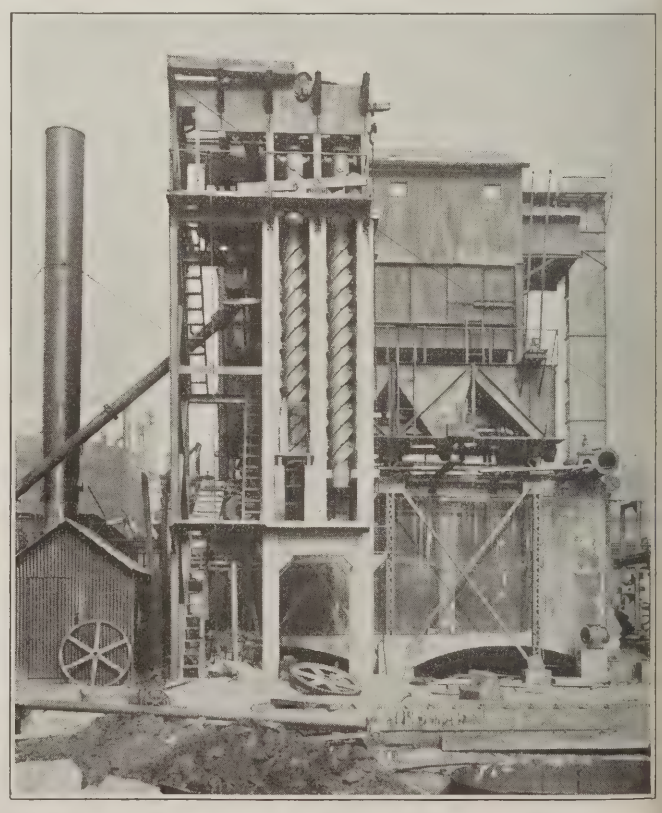
THIS ENGINE DRIVES A FIVE-FOOT FAN

both installation and operation is small. Exact figures on this point are not available, but generally where air shafts are in out-of-the-way places that are hard to get at, a light compact engine makes the best power unit. The accompanying illustration shows a 6-hp. Novo engine driving a 5-ft. fan at a mine of the Kanawha Coal Co., Charleston, W. Va.

A mine owner should be careful in the selection of an engine. A reliable and simple machine that will stand the day-in-and-day-out grind is the only kind to buy.

PLANT OF THE DENVER COAL BYPRODUCTS CO., THE LARGEST LOW-TEMPERATURE COAL BYPR

G-L Low-Temperature Carbonizing Process



SPECIAL CORRESPONDENCE

SYNOPSIS — *Coal is now burned raw wastefully and inefficiently. The process here described reduces the amount of gas evolved by the usual processes of carbonizing and secures an increased output of oils. Fuel of any desired volatile content may be produced.*

COAL in most instances is burned today just as it was when first discovered hundreds or thousands of years ago—that is, it is burned raw. In its natural or raw state bituminous coal burns under ordinary circumstances and manipulation with ease and inefficiency, with smoke and incompleteness. It is difficult, except by means of special furnaces and careful manipulation, to burn raw bituminous coal under a boiler smokelessly; in the ordinary house furnace or the kitchen range it is next to impossible. While smoke —that is, the emission of minute particles of solid carbon from burning coal—does not in itself constitute any appreciable loss, it usually forms a good indication that other and far more serious losses are occurring. Dense black smoke is the telltale of incomplete combustion.

That the burning of raw bituminous coal is an expensive luxury has long been recognized—and the more "bituminous" the coal the more expensive the luxury. In other words, it has long been known that high-volatile coal contained other products of greater value than its heat. These substances are extractable only by distillation. This distillation ordinarily yields a solid residual fuel or coke of low-volatile content, a large volume of gas, a small amount of ammonia and a variable quantity of oils and pitch. There are thus made two major fuels, one solid and one gaseous, both of which may be readily burned, giving complete combustion and no smoke.

The ordinary byproduct coke oven operates at high temperature and yields large volumes of gas together with comparatively small quantities of oils. As a re-

VIEW OF TWO RETORTS, WITH BRICK SETTING REMOVED

N THE WORLD, PRODUCING HIGH YIELDS OF AROMATIC TAR OILS AND SMOKELESS FUELS

sult this process of coking has found most favor where large quantities of gas are or may be consumed in industrial processes such as steel manufacture, or where existing density of population entails a demand for gas for domestic purposes.

Many experiments have been made in low-temperature distillation processes, but these heretofore have presented many difficulties, chief of which has been the length of time required for heat to penetrate any considerable thickness of a coal charge.

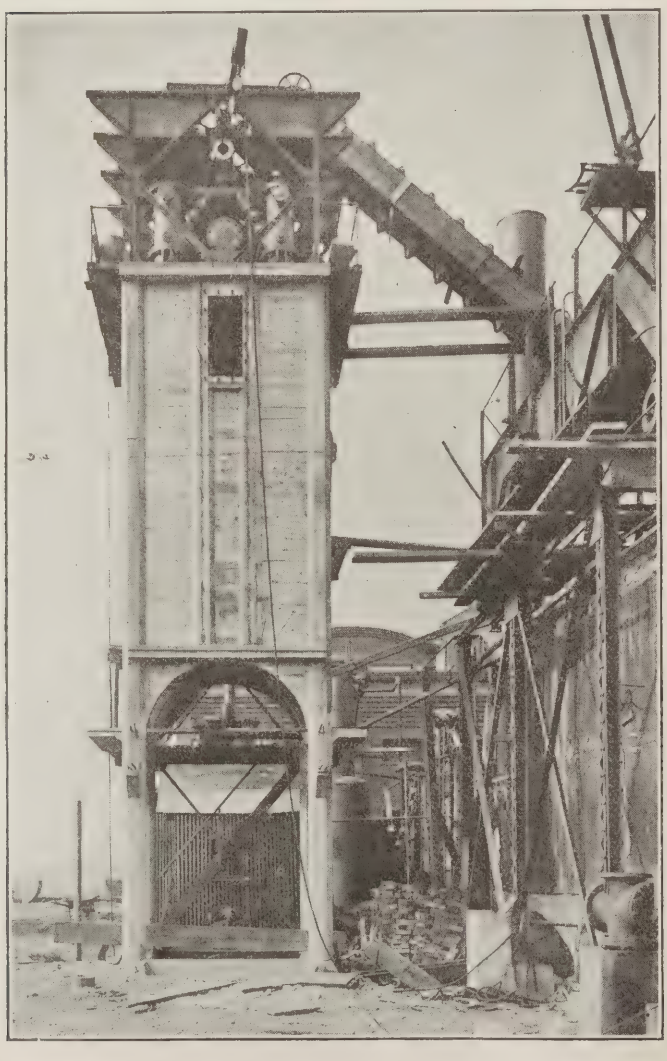
The Denver Coal Byproducts Co., of Denver, Colo., a subsidiary of the American Coal Byproducts Co., 115 Broadway, New York City, has had a low-temperature carbonizing plant in commercial operation for some time, and the results obtained are so significant as to be almost boundless in scope both as to utility and possible financial return. The plant is operated under the Greene-Laucks patents, or on what is known as the G-L process. This differs in many respects quite radically from previous attempts at low-temperature coal carbonization.

The retorts used are arranged in groups, units or batteries of four. They are made of cast iron, about 18 in. in diameter and 18 ft. long, and are set on end. A spiral fin is cast on the outer surface of each retort, which is incased in a firebrick setting. This fin serves a double purpose. It breaks up the currents in the ascending heating gases and materially assists in absorbing the heat therefrom and conveying it to the contents of the retort.

Coal, ground to pass a 20-mesh screen, is fed continuously into the top of the retort. Centrally mounted within the retort is a hollow-stemmed worm. This is revolved slowly by machinery and both agitates the coal charge and forces it downward, thus maintaining an operation which is automatic and continuous. Gas burners external to the retort but within the firebrick setting furnish the requisite amount of heat necessary for the carbonizing process.

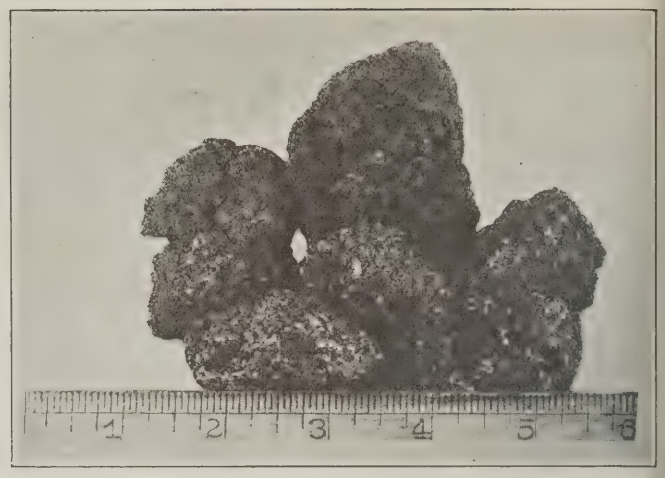
As has been stated, the worm in the center of the retort is hollow. The gases evolved in carbonizing escape through suitable openings into the interior of this worm. At the upper end of the retort the worm shaft passes through a stuffing-box, then through the driving gear that actuates the worm, and its end is finally connected to a piping system in which a vacuum of approximately 24 in. is maintained.

Everyone knows that the less pressure maintained on water the lower is the boiling point. The same rule appears to apply to coal; or, in other words, the higher the vacuum that is maintained in the coking chamber the lower will be the temperature that will induce complete carbonization. In the G-L process, which is closely analogous to boiling in a vacuum, the gases, oils and



CRUSHING AND CHARGING PLANT, AND GROUP OF RETORTS

tars are liberated from the coal at a comparatively low temperature, the maximum within the retort seldom if ever exceeding 1200 deg. F. The oils are thus expelled as vapors without being broken down by heat into gases. Escaping as vapors they are readily condensible into liquid oils after their removal from the retort.



The gas evolved in this process amounts to about 4000 to 6000 cu.ft. per ton of coal treated. Approximately half of this is consumed in coking, leaving from 2000 to 3000 cu.ft. as an excess. This is high in calorific value, running about 700 B.t.u. per cubic foot.

The ammonium sulphate resulting from this process amounts to about 20 lb. per ton of coal treated. The amount of liquids extracted varies considerably with the kind of coal, a fair average for Colorado or Rocky Mountain varieties will show a yield of: Light oils, 3 gal.; carbolic oils, 6 gal.; creosote oils, 12 gal. Runs recently made at the Denver plant showed that 77 per cent. of the oils given off were what are termed aromatics—that is, they volatilize easily—while the creosote obtained was equal in quality to that secured from pine or pine tar.

This process of coking is continuous, with never more than 250 lb. of coal in any one retort at any one time. The capacity of each retort is about 25 tons of coal per 24-hour day, or 100 tons each 24 hours from each unit or battery of four retorts. The speed of the treatment is adjustable within limits permitting of a variation in the length of time that the coal within the retort is

SIDE VIEW OF A RETORT UNIT

DOMESTIC COKE MADE FROM LIGNITE

subjected to the action of the heat from without. The quality of the coke—that is, its volatile content—may thus be governed as requirements may dictate. It is thus possible to make either a metallurgical coke containing 2 per cent. volatile or a high-grade domestic fuel, one that is comparable to and that will behave almost exactly like anthracite, containing 10 per cent. volatile matter. The domestic fuel made by this process is of course lighter, volume for volume, than is anthracite coal. It ignites much more readily. Chemically the fuels are almost identical, and their actions in furnace or stove are exactly similar except that this fuel yields a fire somewhat more flexible—that is, one that will respond more quickly to a variation in drafting. Fuel of this kind made from western coals burns to a fine powdery white ash without the least suggestion of clinkering.

The cost of carbonizing by this process including labor, fixed charges, supplies, etc., is said to be about 50c. per ton of coal treated. The present market value of the products, considering the fuel as being worth $8 per ton and neglecting entirely the excess gas, but including oils, creosotes, ammonium sulphate, etc., is placed at $17.65 per ton of coal treated. The treatment thus reveals decided possibilities.

The installation at Denver, built originally as an experimental plant, has been in commercial operation for several months. Coals (carloads or more) have been tested from Utah, Wyoming, Colorado, Texas, Illinois and Ohio, while small samples from many other localities have been tried out in the laboratory. Oil shales have also been treated, showing results similar to those obtained from coal—that is, the recovery of high percentages of aromatic oils, or unsaturated hydrocarbons. No residual fuel is made from shale, however, the revenue from this treatment beginning and ending with the byproducts.

IT WAS LEARNED, during the construction of concrete ships, that hammering on the forms (by a mechanically operated hammer) produced a vibration which greatly assisted in settling the concrete and completely filling the forms. There is a tendency to use too wet a mixture when it is desired to have a concrete which will completely fill all space in forms, especially around steel reinforcing. Intelligently used, hammering on forms accomplishes the work of tamping with a concrete by no means wet and does the work better. However, concrete beginning to set should never be vibrated; also care should be used not to displace forms. It would seem that this method could be advantageously used in various kinds of concrete work.

Mental Equipment

WHEN considering the problem of new equipment, it is well to bear in mind that the mental equipment of an organization may also be studied with profit. In order to appreciate and desire new apparatus, it is obvious that the buyer must be mentally prepared with a vision and judgment sufficiently advanced to be in position to recognize the possibilities derivable from a change in a certain method of production. If a buyer is nonprogressive in ability, initiative and imagination, he naturally will be likewise in adopting new appliances for his plant. And it is just because there are so many people whose mental equipment disqualifies them from advancing beyond their present type of machinery that salesmen and sales literature must continually hammer at and besiege them.

Buyers as a rule have to be prevailed upon to install new equipment. This process is like hitching the wagon before the horse. The natural and Utopian way, of course, is no other than that of every buyer eagerly adopting on the moment the latest and most improved type of equipment in his line. This is as it should and would be were it not that the mental equipment of the buying public lags behind like a stubborn mule, and in turn places a checkrein upon inventive genius. Mechanical equipment is limited by the mental equipment of the prospective user.

The bituminous coal industry is a rich field for men who possess a mental equipment that is not content with merely keeping pace with competitors. Coal mining is influenced so widely by geographical and local conditions that the proper equipping of a mine is an individual problem and not a matter of duplication. Devices that may show excellent results in one mine may prove a disastrous experiment in another. Invariably the mechanical equipment is blamed in these instances, whereas it is the mental attitude of the purchaser that is at fault. Such mistakes could be avoided if buyers would familiarize themselves with the growth of improvements.

Necessarily this will not mean the adoption of every piece of new machinery placed upon the market. On the contrary, it will assist in an efficient selection of the practical from the chaff, and particularly in choosing new equipment that will be compatible with the physical conditions of any one mine. Mental equipment is as much a matter of knowing what new appliances to reject as what to buy. Not only this, but in order to be really efficient it should anticipate and demand better equipment, and not be satisfied to adopt new mechanical devices until after their worth has been fully proved by universal acceptance.

This kind of mental equipment is rare and invaluable, although there is no real reason why it should be unusual. Just as the progressive man, in order to keep abreast of the times, scans the daily newspapers for the latest news, so is it necessary that the trade papers be reviewed by the buyer if he wishes to keep in the foreground of his profession. The contents and advertising of the trade journals are the common meeting ground of the buyer and seller, and as such demand more than cursory attention. They supply and stimulate interest and investigation. Real information always has to be sought, seldom, if ever, coming via a golden spoon.

To be taken in conjunction with information—and quite as important—is the buyer's ability to use his imagination. Modern business has not yet fully recognized the great value of this ability, the faculty of looking ahead for any length of time. This is the privilege of individuals in planning their careers. Once in a great while, however, a man with imagination comes to the top in a large organization, and if he is not curbed, imbues and directs the business in such a spirit. To secure such mental equipment for an organization is as important as a careful consideration of the mechanical equipment. Neglecting the human element is a short-sighted policy.

Finishing the Job

In thinking of reasons for subscribing to the Victory Liberty Loan, let Americans who remained at home consider the case of Sergeant Burr.

He went out into the open, a slip of a lad, just elevated to his sergeantcy, on a hurry order to take his patrol inside the German line, and establish communications preparatory to the attack. And, finally, his voice came in youthful treble over the wire to headquarters.

In quick, jerky sentences he outlined his location, the lay of the land, the number of machine guns—eighteen—bristling directly ahead, and then he was ordered to leave one man at the post, and to seek cover.

After a long wait the same voice came trailing in over the hidden wire;

"Sergeant Burr speaking, Sir——."

"That kid again!" muttered the officer, and, aloud; "What's keeping you? You were ordered to get to cover and leave the wire in charge of ———.

"Yes, sir," interrupted Sergeant Burr, "I couldn't think of ordering any of my men to stay in such a place. I'm staying myself!"

Thus, out there under the French sky, Sergeant Burr of the A. E. F. carried on—in range of a dozen and a half machine guns, on a shell-swept terrain. He guards a bridgehead on the Rhine border today, the Distinguished Service Cross upon his heart.

Sergeant Burr is finishing his job! It is a very splendid and gallant way of finishing it. For his fellow citizens the obligation to finish the job must certainly be as binding! Our Victory Notes will make us all feel a little more qualified to welcome back the Sergeant Burrs of the American Army.

Steel Mine Ties

By R. B. Woodworth
Pittsburgh, Penn.

A SHORT time after it had been proved conclusively that steel was the most practical form of mine timbering, the use of steel for mine ties rapidly developed. During the years 1909 to 1917, the Carnegie Steel Co. sold 317,174 tons of steel cross ties, a large percentage of which were used in mines.

The steel tie is no longer an experiment. The success attending its use has established its superiority over the wooden tie. During the last few years their output has been restricted because of the difficulty of securing the steel, but a more normal stage is approaching, an age when steel will be plentiful and an age of reconstruction, when only the best equipped collieries can compete for the world trade demanding American coal.

The fundamental considerations on which the advantages of the steel tie over those of wood rest are the following:

1. *Headroom*---One of the most important features of the steel tie is the headroom gained through its use. These ties are only ½ in. in thickness, representing a gain of 2½ in. over the wooden tie. They are especially adapted for low beds of coal, permitting larger cars and

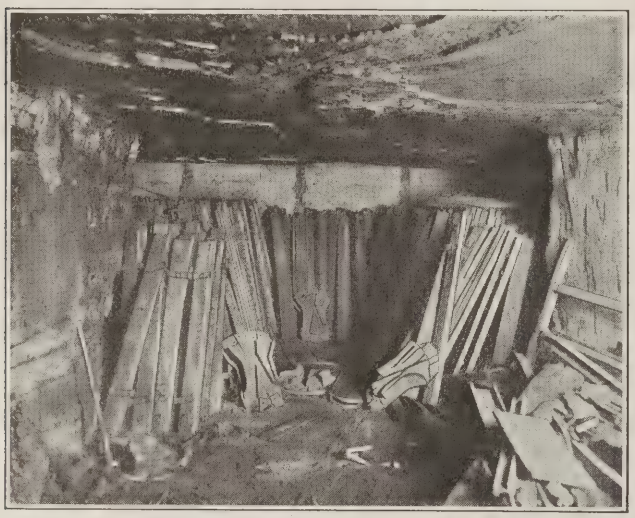


FIG. 1. UNDERGROUND STOREROOM FOR STEEL TIES

heavier topping. No excavations are needed to lay the ties, and they can be spaced much farther apart as their shallow depth permits the track to rest on the ground. They are so light and compact that great numbers can be stored in a small space. Fig. 1 shows one of the stockrooms of the Majestic Coal and Coke Co., Duquoin, Ill., where hundreds of Carnegie steel mine ties are stored ready for instant use.

The following is an extract from a paper entitled "War Economies," by George B. Pryde, general superintendent of the Union Pacific Coal Co., read before the Rocky Mountain Coal Mining Institute at Colorado Springs, Sept. 5, 1918:

> The use of steel ties has been experimented with to some extent for several years, and these experiments have reached the stage where their use is recommended, especially in low seams. They are particularly adapted for this kind of work, for they provide a good rigid track and give greater headroom than the ordinary wooden tie, thus cutting down the taking up of bottom to provide sufficient

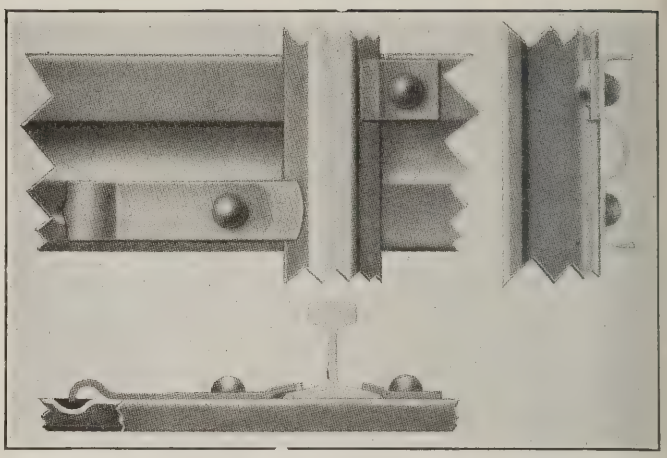

FIG. 2. TIE FOR GATHERING TRACKS IN MINES

height for haulage purposes. They are easily and quickly laid, and while they cost more than the wooden tie their longer life and adaptability as a labor saver recommend their more general use in mining low seams of coal.

2. *Endurance*—In mining it is frequently necessary that the track be exposed to excessive moisture, and that it be moved frequently. These have resulted in one of the most important advantages of the steel tie. The life of a wood tie under these conditions is short at best. Even when specially treated such ties can seldom be moved more than twice. On the other hand, steel ties under the same conditions give many times the service rendered by wood ties and can be moved repeatedly and easily. A few complaints have been made of their rapid corrosion when placed on damp floors, but this seems in no way to shorten their service. However, it can be easily overcome by a treatment in coal tar or asphaltum. Furthermore, when a sufficient quantity of such ties are desired, steel can be furnished with a certain admixture or alloy of copper, which has the effect of making the steel noncorrosive.

3. *Fire Risk*—The presence of wood in the mine always increases the possibility of fire and is a continual menace both to life and property. We can easily recall

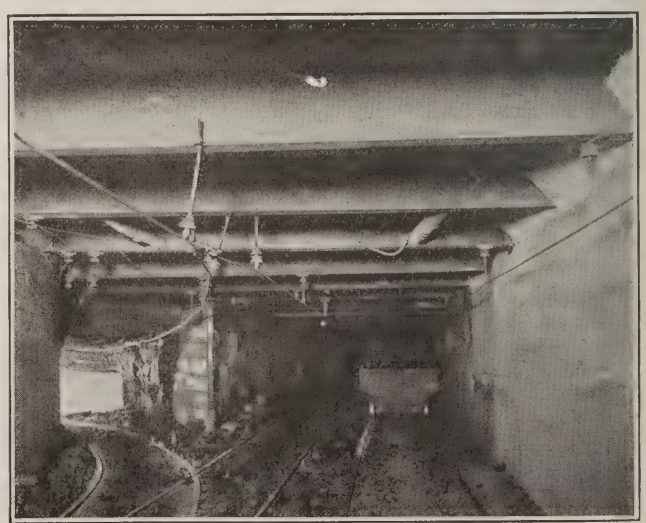

FIG. 3. STEEL CROSS TIES ARE REPLACING WOOD TIES IN THIS ENTRY

disastrous fires and the great toll of life taken thereby which would not have occurred had it not been for the large amount of combustible material present. The use of steel within the mines is fire insurance—an elimination of fire risk. Why should we not have fireproof construction below ground as well as above?

4. *Scrap Value*—At the end of their period of usefulness steel mine ties have a scrap value of approximately one-third their original cost. Wood after a short period of service in the mines has no value whatever, but becomes a continual menace to life and property. The first cost of steel is a trifle more than that of wood, but its longer and better service and its scrap value make it the more economical.

5. *Simplicity*—The design of steel mine ties is simple. The Carnegie steel mine tie, one type of which is shown in Fig. 2, is so constructed that one blow of the hammer firmly and rigidly holds the rail in place, and accurately to gage, preventing derailments and saving time. There are no loose bolts or fastenings, nothing to get lost, as these are part of the tie. One simple turn of the attached clip is all that is necessary. This

FIG. 4. SHAFT BOTTOM LAID WITH STEEL TIES

simplicity of construction and lightness make the use of steel ties a great economy in time, money and labor.

Considering the lateness of the use of steel cross ties for mining operations their utilization is widespread. The Union Pacific Coal Co. has installed steel mine ties in its mines located at Reliance, Superior, Hanna, Rock Springs and Cumberland, Wyo. They doubtless have had much to do with increasing the output of these mines, the total yearly production of which amounts to 3,600,000 tons of bituminous coal.

In Mine No. 9 of the Old Ben Coal Corporation at West Frankfort, Ill., both steel mine ties and steel timbers have been installed. As the average thickness of the bed is 8 ft. 6 in. these ties and timbers were not installed for the purpose of gaining headroom but because they have been demonstrated to be economical in every respect. The daily capacity of this mine averages 4500 to 5000 tons. This represents quite an increase over the output when wooden ties and timbers were employed.

Fig. 3 shows the main entry of Mine No. 9. About 1600 ft. of this entry has been timbered with steel I-beams resting on concrete walls. The roof has been lagged with wood. Steel cross ties are replacing the wood ties in the track. About four steel ties are now

FIG. 5. LOOKING TOWARD MAIN SHAFT IN ILLINOIS MINE

used per rail, and as the wooden ones decay they will gradually be replaced by steel.

Fig. 4 shows the shaft bottom of the south entry of this same mine. The shaft bottom is a highly strategic point at a high-production plant. Through it passes the tonnage of the mine. The capacity of the shaft is greatly increased by the facilities at and around the bottom itself. Conditions here have been wonderfully improved by the use of steel—a middle line of props has been eliminated by the use of steel timbers and much headroom is saved by steel ties, thus permitting larger cars with heavy loads.

The mine of the Majestic Coal and Coke Co., at Duquoin, Ill., is shown in Fig. 5, looking toward the main shaft. About 800 ft., of the entry is timbered with steel and the track is laid partly with steel and partly with wooden ties. Fig. 6 is a good illustration of the use of cross ties in low beds of coal. Their many advantages are obvious. The photograph was taken in the Wenonah mine of the Turkey Gap Coal and Coke Co., Wenonah, W. Va., where steel cross ties are used extensively. This company also uses the steel cross ties in its Modoc mine at Springton, W. Va. The Pocahontas Fuel Co., Inc., is using steel cross ties in the Jenkinjones mine, at Jenkinjones, W. Va., and in the Boissevain mine, Boissevain, Virginia.

In the 1918 mining catalog published by the Consolidated Keystone Publishing Co., Inc., page 466, is shown a comparison of installation and maintenance

FIG. 6. SHOWS USE OF CROSS TIES IN LOW BEDS

costs between wood ties and steel ties for room work in mines. The following is a summary:

Based on rooms 280 ft. long with steel ties spaced 4 ft. center to center and wood ties 2 ft. center to center, this estimate contemplates using each wood tie in two consecutive rooms and after the second year renewing annually 15 per cent. of steel ties, or ten new ties per year per room. The total cost at the end of life of first room for steel is $22.40; for wood, $19.60. The total cost at the end of life of second room for steel is $24.50; for wood, $28., or a saving of $3.50 when steel was used. The total cost at the end of life of third room for steel, $29; for wood, $47.60, or a saving of $18.60 in favor of steel. The total cost at the end of life of fourth room for steel, $33.50; for wood, $56, or a saving per room in favor of steel ties of $22.50.

The miners themselves prefer the steel ties because they entail much less work. If given their choice they will take steel any time. By using wood they are decreasing their production, as the time and labor involved in laying wooden ties is greater. Wood is becoming more and more difficult to secure, and the large sales and widespread adoption of steel ties are proving their utility.

Back Up Efficient Coal-Mining Apparatus with Efficient Office Equipment

By G. W. Laine, Jr.
New York City

After several years of intense wartime activity, a breathing spell is being experienced. This gives opportunity for a comparison of operation, under the pressing conditions of the past, with standard economical practice and the adjustment of certain factors that will lead to more efficient methods for the future.

It is highly essential for everyone interested in economical production and operation to study past conditions, for unless the lessons of the past are used as stepping stones, the pressure of competition and unforeseen circumstances ahead will be likely to cause difficulties.

During the pressure of war and the accompanying high prices, it was possible for many inefficient systems to be used without serious losses; but with readjustment there must be investigation of every means at our disposal that will promote economy of operation.

Many large concerns are reorganizing their departments, giving particular attention to their accounting work and making studies with the view of installing those mechanical aids best suited to such work. Not only is it necessary that consideration be given to efficient accounting equipment, but it is now realized by many that there is to be a more serious shortage of labor than was anticipated.

Unless the equipment for calculating and preparing data necessary to the operation of mines and other industries is secured, difficulty will be experienced in getting promptly, in suitable form, the vital facts essential to the maintenance and operation of a successful plant.

It is well that improved mine equipment is being studied at this time with a view to securing the most up-to-date devices and methods. Whatever equipment is considered, whatever is found to be most applicable, and whatever is adopted, there is all the more reason that the efficiency of operation, that the economy of mechanical appliances, should continue into the office where facts are compiled, where the records are kept and where the information necessary to the welfare of the whole organization is at hand for those who administer the affairs.

The efficiency of office equipment affects that of all other equipment. Machines may do good work in the mine, power distribution may be of the best, but unless the calculation of costs is efficient, the economy is not complete. Economy of operation also means economy in office methods. The days of paper and pencil for handling the "figure work" of the mill, the mine or the office are passed, and today machines are assuming part or all of the burden.

A careful investigation should be made of equipment of this kind, for when there are machines for adding and listing, machines for adding and upon which other calculations can also be performed, and also calculating machines which handle multiplication and division as easily as addition, and upon which subtraction can be performed directly, it is desirable to obtain the instrument that fills the need most completely.

The difference between the old methods of figuring and the modern calculating machines is so great that many opportunities where the old methods are employed exist for waste. Even the difference between machines is sufficient to cause enough loss to be appreciable.

No machine for handling figures is properly a calculating machine unless it will multiply, divide and subtract as readily and directly as it will add. These features are all available in the Monroe calculating machine, which has many advantages in the preparation of the intricate data involved in coal-mine accounting.

Considering only the cost report required of bituminous coal production by the Federal Trade Commission, so extensive is the work involved in computing the data required in the different subdivisions of the report, such as mining, ventilation, drainage, stripping, haulage, power, overhead, general expense, besides the various accounts and the cost figures which are necessary in the management of mines, that a considerable force must be maintained to handle this work. Intricate calculations are also necessary in the engineering department. Here the adding feature of calculating machines plays a much less important part, but the ability of a machine to extract square and cube roots is of great assistance.

It is remarkable the savings that may be accomplished by even one machine of this kind, and many concerns are adopting them in all departments because of their adaptability to all kinds of calculations. Some concerns

with this machine have reduced to hours work which formerly required days to perform. One which I have in mind, by using the Monroe 45 min. every morning, was able to prepare reports daily which formerly could not be pepared at greater frequency than once a week, but which were necessary to the quality of the product and were desired as often as possible.

One of the coal operators in western Pennsylvania says of the machines used in its offices, that "without a doubt the little machine is a valuable asset in any line where accurate figures are required; but on the A-1 sheets direct from the mine, where the tonnage is figured both gross and net, from pounds through the proper channels to final invoice totals, it is indispensable. Especially is this true since the Government requirements are so strict in regard to commissions and specific prices. Again, on the cost sheet—the most vital and necessary organ between mine and head office, and no doubt the most dreaded work of the payroll clerk, where the itemized distribution of cost is averaged to a final total—its accuracy and rapidity has cut the work more than 50 per cent. and pulled the thorn from previously abhorred and ofttimes neglected labor."

Just how these machines handle calculations will be interesting when such devices are being considered on their merits for handling the burden of figures. Perhaps the greatest saving is due to the absolute accuracy of the machine and the fact that because of a visible check it is not necessary to repeat any operation in order to have a positive proof of accuracy. There are only three simple parts to be considered in the operation of the Monroe machine. These consist of the keyboard and two dials; the upper dial having a capacity of 8 figures and the lower dial with 16 figures.

In a simple problem of multiplication, the figure to be multiplied is placed on the keyboard, where it remains until the work is finished. The number by which this is multiplied is turned into the upper dial by means of an operating crank at the side of the machine. This is easily turned and registers the figures of the multiplier in the upper dial. Simultaneously with the registration of the figure in the upper dial, the result of the multiplication of the factor on the keyboard by the number on the upper dial appears on the lower dial. The visibility of the three factors on the machine is sufficient proof that the result on the lower dial is correct.

The comparison might be made that writing the figure on the keyboard by depressing the keys requires approximately the same or less time than writing the number on paper. Writing the multiplier on the upper dial by turning the operating crank is approximately the same as writing the multiplier on paper. With paper and pencil, we are only ready to start multiplication, with the machine the result has already appeared on the lower dial.

Work involving the multiplication of large numbers, such for instance as those of six or seven digits, by numbers of six digits, which would require approximately 6 min. by paper and pencil without any assurance of accuracy—that is, multiplied but not checked—would require only about 45 sec. with this machine, and the machine results would be correct. This is a saving of over 88 per cent. in time, and if the comparison were made with pencil and paper work, including the time for verification, nearly 100 per cent. of the time would be saved.

To make a comparison in a different way, it might be stated with absolute veracity that the multiplication of seven digits by six digits would require ninety times as long by paper and pencil as with this machine, and we would not be sure of our results if accomplished by the long way.

Simplicity and accuracy are not the only features which make this device an economical factor in business arithmetic. The flexibility of the machine makes possible the continued multiplication of one factor by several others with much fewer operations than would be required for separate multiplications. If we have one number to be multiplied by several others, as would be the case in the distribution of a given amount over several accounts, according to percentages, we would set the constant factor, or the number to be multiplied, on the keyboard and turn the first multiplier into the upper dial. The product appears on the lower dial.

Now, in multiplying by the second number it is only necessary to change the number on the upper dial from the first multiplier to the second multiplier, and the result is changed accordingly. The number on the upper dial is changed from one number to another by forward or reverse rotation of the operating crank in the proper position; for example, if a number on the upper dial was 23 and we desired to multiply by 52, we would make one reverse turn of the crank in the units position, which would change the 3 to a 2, and then shift to the 10's position, and by three forward turns of the crank change the 2 to 5. We would then have the result on the lower dial as the product of the number on the keyboard by the number on the upper dial.

Results Can Be Determined Rapidly

In this way, no matter how many multiplications are to be performed of a given number by others, the results can be determined rapidly. It will readily be seen that in work of this kind a much larger percentage of the time can be saved than even in the case of multiplications, where different numbers are involved.

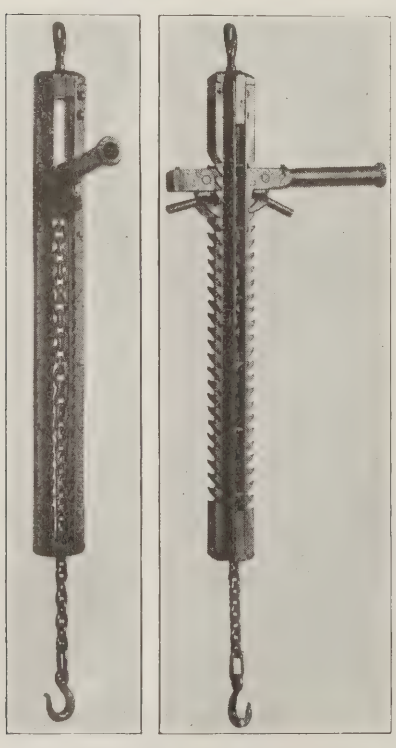
Addition is a simple process. The numbers to be added are set on the keyboard, and by a forward turn of the crank the number is added to that appearing on the lower dial, the keyboard being cleared with each stroke of the crank and made ready for the set-up of the next number.

Subtraction is equally as simple. The first number is turned into the lower dial by a forward turn of the crank, and the number to be subtracted is set on the keyboard and deducted from the figure in the lower dial by a reverse turn of the crank. It will be noticed that no mental work, whatever, is involved in these computations—it being merely necessary to place the figures on the keyboard and add them to those in the lower dial by a forward turn or subtract them by a reverse turn.

As division is merely a series of subtractions of the divisor or multiple of the divisor from the dividend or number to be divided, the process on this machine is no more complicated than any of the other operations. Reverse turns of the operating crank register red figures on the upper dial of the machine. Division is performed by turning the number to be divided into the lower dial and then setting the divisor on the keyboard. There are no complicated rules to learn, for the work is done in the same sequence as with paper and pencil.

Arithmetic as found in business, regardless of whether it is concerned with extending invoices, figur-

ing analyses of products, computing costs or solving complicated formulas involving square or cube roots, is after all only a combination of four simple processes —addition, subtraction, multiplication and division. The machine which will do these four things and save from 60 to 95 per cent. of the time and effort required by the usual processes is a benefactor to the cause of economy.



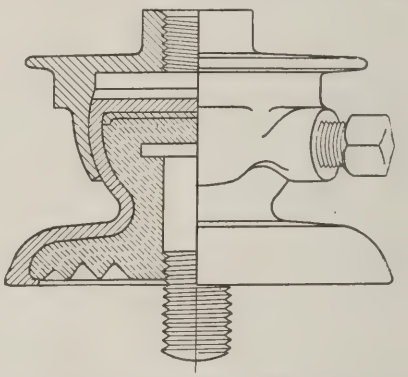
Because of the direct operating feature, the two-way mechanism, making possible addition and subtraction by simple forward or reverse turns of the crank, may be decidedly curtailed. For example, if it was desired to multiply by 98 it would only be necessary to multiply by 100, by a forward turn of the crank in the 100's position and two reverse turns of the crank in the units position; or in other words, to add the number 100 times and to subtract it twice.

No difficulty is experienced in understanding any of the operations or "shortcuts" on this machine, and anyone can operate it after a few minutes' instruction. This is a feature which should also be considered when investigating calculating-machine equipment, for if an experienced operator is necessary, much depends on the capability of the operator and also on his attention and goodwill.

The last, but one of the most important factors governing the selection of equipment to facilitate economical operation, should be its durability, the repairs which may be necessary and the costs and delays incidental to any trouble which may develop. The construction of the Monroe and the service departments available without charge to the user are in keeping with the standards of the organization of its manufacturer.

Universal Lifting and Pulling Jack

The Elk Engineering Works, of St. Mary's Penn., is placing on the market what it has termed the "Universal lifting and pulling jack." This is shown in the accompanying illustration. The body of the device is built of steel angles with malleable iron end pieces. The hook at the upper end is drop-forged. The chain travel is equal to 3 ft., and a movement of the lever either up or down causes a pulling action on the chain. There are no gears or attachments, and the entire device weighs 70 lb. It is well adapted for moving mine timber or for other work where a powerful pulling or lifting apparatus is desired. Its simplicity and ease of operation will appeal to mining men.

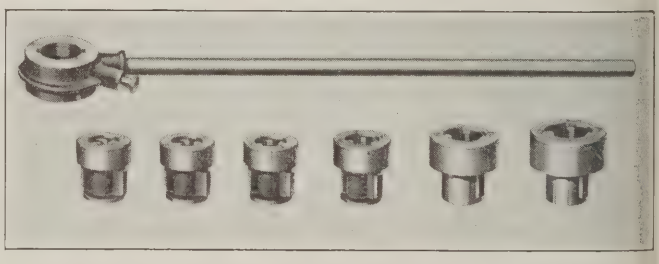


POWERFUL PULLING JACK

New Hanger Aligns and Plumbs Trolley Wire

Every man who has strung trolley wire in a mine knows the difficulty of keeping the trolley wire free from kinks at every suspension point. The Ohio Brass Co. has now produced a trolley hanger (Types SH and SK) which overcomes this difficulty.

The insulating member of the Type S hanger has a half ball top over which is clinched the socket casting. Although the two pieces cannot become separated the lower half of the hanger is free to turn or be tilted in any direction after the hanger has been attached to the roof or timber.



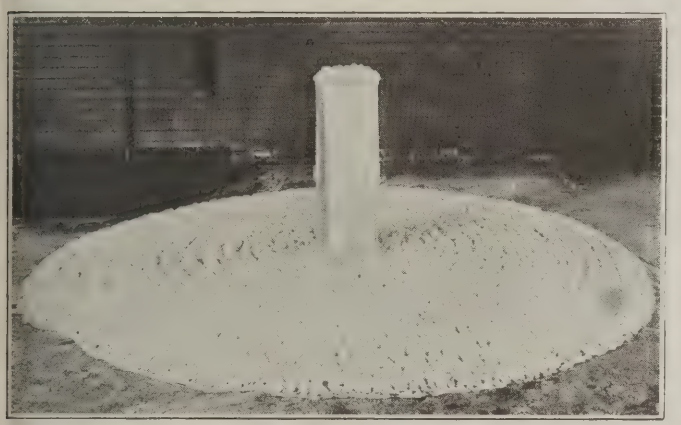
THIS HANGER KEEPS WIRE FREE FROM KINKS

With the set screw loose, the hanger is screwed on the expansion bolt or lagged to the timber. The clamp is then tightened on wire and hanger. The lower part of the hanger is twisted and rotated until the wire is true and straight. Each of the three set screws is turned up, which makes a rigid unit of the suspension.

Types SH and SK are identical in principle. The SH is designed for lagging to timber, while the SK is screwed onto an expansion bolt driven into the roof.

New Ratchet Pipe Threader

The Borden Co., of Warren, Ohio, has placed on the market a new pipe-threading tool known as the No. 3 Beaver, Jr. This is a ratchet tool with various sizes of cutting heads, these heads being made for pipe from $\frac{1}{8}$ to 1 in. in diameter. The ratcheting feature of this tool is one of importance. It permits the threading of pipe in places that would otherwise be inaccessible, such as in narrow trenches or ditches, between the studding or rafters of buildings, or in cramped quarters generally. Of course, the ratchet does not prevent the tool from being used like an ordinary pipe threader at the bench vise. Even here the ratcheting device has its advantages, since it permits the operator to move the lever through the arc that is most convenient.



RATCHET TOOL WITH VARIOUS SIZES OF CUTTERS

Firefoam Extinguishers

The ordinary means of extinguishing a fire is to isolate it from its supply of oxygen or cool the fuel below the combustion temperature. As a general rule this isolation or cooling is accomplished by a coating of water. When water is thrown upon a fire it forms a thin film over the surface of combustible material, excluding the atmospheric oxygen. This cools and extinguishes the fire. A similar result may be accomplished by an inert gas—that is, one that will not support combustion—such as carbon dioxide.

One of the chief difficulties experienced with the ordinary so-called chemical extinguisher is that the gas evolved, although heavier than air, is soon dissipated either by diffusion, by air currents or both. The full quenching effect of the nonsupporter of combustion is thus either lost or is at best only temporary.

In order to overcome this difficulty the Foamite Firefoam Co. has developed and placed upon the market an extinguisher that in outward appearance is similar to ordinary chemical extiguishers, but which possesses different qualities when in action. The chemicals employed in this device generate roughly eight times their volume of carbon dioxide gas and imprison this gas

THE FIRE-SMOTHERING "PANCAKE" THAT RESULTS WHEN THE CHEMICALS ARE MIXED IN AN OPEN CONTAINER, AND A STAIRCASE THAT WAS SAVED FROM FIRE BY AN APPLICATION OF THE MIXTURE

within a vast number of minute bubbles. The nonsupporter of combustion is thus confined in a thick blanket of lather tough enough to last for several hours, and one that will adhere tenaciously to any surface that it strikes.

The two liquids employed are held in separate compartments of the container and are not mingled until ejected from the nozzle of the hose. Once mingled they promptly react upon each other, forming carbon dioxide. One of the illustrations shows the effect of mixing the chemicals in a can and allowing the resulting spume to run over the top. A "pancake" of fire-smothering carbon-dioxide lather is the result.

Another illustration shows a stairway that was drenched with gasoline. This was then set on fire and extinguished with one of these extinguishers. The resultant fire-smothering blanket may plainly be seen coating the surfaces of the stairway and brick wall back of it.

This coating, as has been said, is sufficiently tenacious to remain in place for a long time. If it is desired to remove it from the surfaces coated before it is dry, this may be done by sweeping or by shoveling if the thickness is great enough to warrant this method. It eventually dries to a fine white powder that may be readily swept from building surfaces with a broom or brushed from clothing with an ordinary clothes brush.

This fire-fighting apparatus is now manufactured in sizes ranging from a 3-gal. fire pail and a 2½-gal. hand extinguisher up to 500 and 800 gal. engines mounted on wheels, skids or trucks. Special apparatus or engines of special design or size may also be built. This means of fire protection possesses one peculiar advantage—it may be rated and installed upon a strictly scientific or engineering basis. If a given surface area is to be protected the amount of chemicals necessary therefor may be calculated with exactitude.

This method of arresting combustion, although applicable to any fire, is particularly effective in combating fires in oil tanks, reservoirs or storage places where water (on account of its greater specific gravity) would be useless. Some of the largest of oil tank fires have been promptly extinguished by this means.

For work inside the mine it seems to possess great possibilities, in that the extinguishing gases are permanently held in the retaining bubble blanket and cannot readily diffuse and foul the air.

Increasing Use of Gate Valves

Gate valves are finding increasing favor among mining men, and for certain classes of work are taking the place formerly held by globe valves entirely. For water lines they give a quick, sure opening which is not so likely to clog as is the case when the globe valve seat is to be passed. For slushing work where the water is of high acid strength, an iron body valve, extra heavy type, with brass gate is used. On breaker, shaker and loading gallery lines a wood-lined iron body gate valve of special design, the patent of Isaac Beaver, is giving long-time service. Some foremen are inclined to use gate valves for steam lines also, but the number thus employed is small. The "ground seat" valves still have the preference for this kind of work at present.

Overstocked Condition of Coal Market Does Not Make for Maximum Output

Stocks of bituminous coal, as displayed by the survey recently completed by the Fuel Administration, and which is given on page 839 of this issue, are larger than was generally supposed, and it is the opinion of officials having to do with coal that no important increase in production will take place before August. Even then it is predicted that production will climb only slowly. The stimulation to production which usually comes in August is due to a considerable extent to the fact that the Lakes are in a position to handle maximum tonnage. Owing to the large stocks in the Northwest, it is anticipated that this stimulation to increased output will not be so great this year as has been the case formerly.

Rumors of contracts being made at low prices continue to reach Washington, but the unsettling effect of such rumors are expected to be discounted to a considerable extent by the publicity which now is to be given contracts for railroad fuel. At the request of J. D. A. Morrow, general secretary of the National Coal Association, the Director General of Railroads has sent out instructions that the publicity is to cover current orders as well as contracts.

Whether the situation is to be aided by the Industrial Board of the Department of Commerce probably will be decided in the near future. Secretary Redfield has put the issue squarely up to Director General Hines and has indicated that the board will be dissolved at once if Mr. Hines will not give it his support.

In a report on the business situation issued by the Committee on Statistics and Standards of the Chamber of Commerce of the United States, the following reference is made to coal:

"There has been a failing off in the demand for coal and a consequent decrease in production. Last fall bituminous coal was produced at the rate of twelve million tons per month. Today it is seven million tons. The mild weather and early spring also were factors in decreased demand. Mines are running from three to four days a week.

In normal times there is always a slackening in demand but during the war production was at the maximum all the time and the present slackening is more in evidence than normally. Prices have not varied since the restrictions were removed. High grades have increased slightly and low grades have fallen off. The coal operators have shown reluctance to reduce prices. There is a heavy export demand but ships cannot be had to move coal wanted abroad. Production of anthracite coal is about normal."

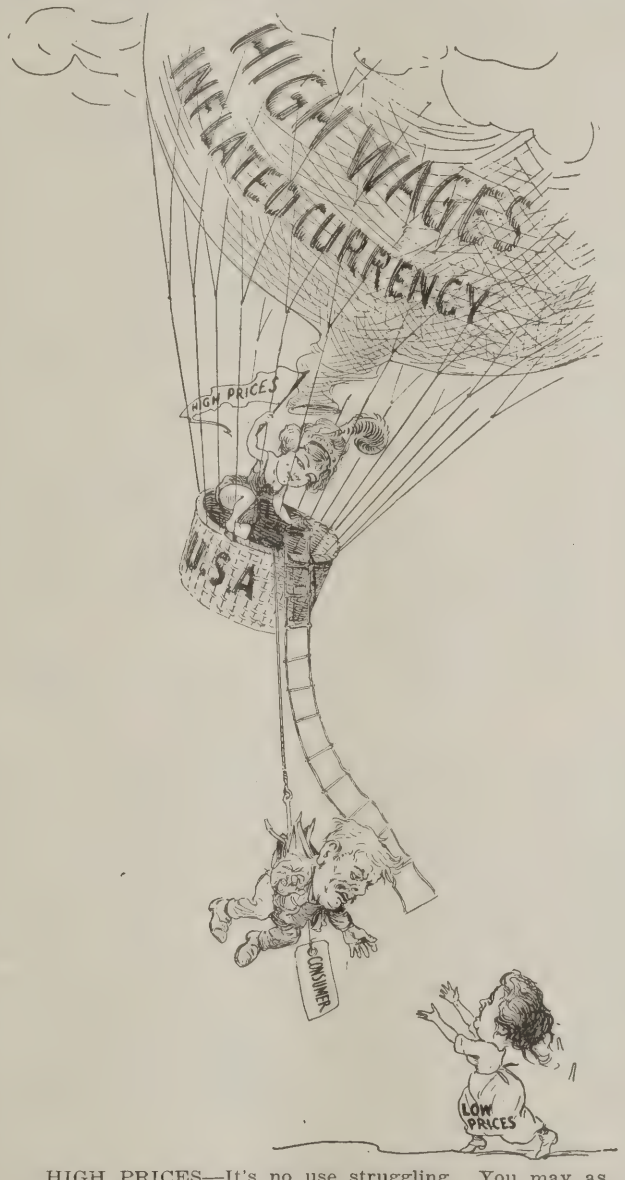
Railroad Administration To Take Over Coal Traffic Bureaus

It now is practically certain that the Illinois-Indiana and Ohio coal traffic bureaus will be taken over by the Railroad Administration. These bureaus formerly were conducted by the railroads to gather coal statistics and were turned over to the Fuel Administration. The Fuel Administration soon will be a thing of the past, and some apprehension has been felt as to the future of these bureaus. It is understood, however, that the Railroad Administration has been impressed with their value and that they will be permitted to go ahead with their work without any interruption.

Coming Annual Convention of National Coal Association

Every effort is being made by the National Coal Association to make its annual convention of more than average service to the coal operators of the country. The meeting is to be held in Chicago, May 21, 22 and 23. Since there is an unusual number of uncertainties besetting the coal trade at this time, it is believed the exchange of ideas at this meeting will be of more than ordinary value. Work on the program has not been completed, but Dr. H. A. Garfield, the Federal Fuel Administrator, and other prominent figures having to do with the coal industry will be heard.

Several important amendments to the Association's charter will be voted upon. Officers and members of the board of directors will be chosen for next year. The members of the board will recommend that J. D. A. Morrow, now the general secretary of the Association, be made a vice president. Mr. Morrow will continue to direct the activities of the Association. Since his duties largely are executive, and not secretarial, it is the idea of the board of directors to authorize the selection of a secretary who can relieve Mr. Morrow of some of the secretarial details.



Advantage will be taken of the gathering of so many coal operators to demonstrate at the convention the details of the work of the open-price trade bureaus.

The coal division of the Geological Survey is much gratified as a result of the success of its plan wherein the local trade associations submit statistics. While the data from these sources are not so complete as are those furnished during the war by the district representatives of the Fuel Administration, it is certain that no other plan could be devised to secure such information without large appropriations being available.

EDITORIALS

At Least One Commodity Is Cheaper—Money

SPEAKING generally wages have not risen appreciably when measured in the goods for which wages are exchangeable. They cannot rise figured in goods, because there is only a certain amount of goods in the world to divide. The prices of any given goods have not increased much when measured in the commodities for which the goods in question may be exchanged. Some wages measured in goods are a little higher than they ought to be. Some prices measured by the prices of other goods would have to be lowered to produce perfect justice. But on the whole, goods are goods, and the price of all of them cannot be too high as measured in terms of one another. Wages are really nothing but goods; they can only be made high by a plethora of goods; they can only be made low by a scarcity of product. They are only high in comparison with money. We can always increase the quantity of money, and make wages and prices rise proportionately to the quantity of money in circulation. But the goods will only *appear* to be dearer and the wages will only *appear* to be higher. It is not dollars we work for; we labor for goods or for the power to buy goods when we will, and goods are none too plentiful just now. So high prices and high wages do not help or hinder us, unless the changes in price and wages are unequally distributed. That is usually the case when there is a readjustment of these items. Some persons profit and other persons suffer. The profiting of one and the losing of another, the bettering of John and the injuring of Jack, balance each other. The only safe bet is in large production. That is a joy that we can experience without having a headache in the morning.

HIGH PRICES—It's no use struggling. You may as well go up with the basket, for with high wages and inflated currency in the balloon it can't do otherwise than ascend.

They tell the story of a farmer who complained that he had been charged too much for a buggy. He had bought one some years before, and he remembered that it did not cost anything like as much as the new one. The hardware merchant looked up his old accounts and found that the farmer had not paid for the first buggy in money but in wheat. So he wrote to the farmer and told him he would refund him his money, let him keep the new buggy, deliver him a good piece of household furniture and a good kitchen stove if only the farmer would bring him as many bushels of wheat as he delivered to him for the first buggy. The buggy was cheap, not dear, as measured in commodities. Like the farmer we need to learn that prices are *not* high in commodity values while all commodities *are* high as compared with money. The unions and the Government printing presses of the world have made money low in commodity value. There is no hope that the prices in the United States will go down while the unions hold their own and the volume of currency remains unchanged or even increases (for bonds are still being sold) so what is the use of waiting for low prices? We shall see higher prices before very long.

Somehow the public believes itself independent of a little item like inflated currency. It is ready to believe that its own psychological condition, its own thoughts about the prospects of business cannot be changed; but it holds that the inflation of the currency can be overlooked if only one will squint really hard or hold a hand over one eye. The public is partly right, however. The inflation of the currency can be in a degree minimized. For instance, in India there has been at all times a wonderful absorption of silver money. The people make it into ornaments. In America there has been an influx of gold and an increase in credit instruments (as for instance Liberty Bonds). They don't depress the value of the dollar as much as they well might, having in consideration their overwhelming volume. The reason is because the people are not circulating either, as freely as they might, nor as freely as they will when prosperous times come, when every one will seek to make the most of coin and credit.

Low-Temperature Carbonization

WE PRINT on page 810 of this issue a description of the low-temperature coal-carbonization process employed by the Denver Coal Byproducts Co., of Denver, Colo. This process, known as the Greene-Laucks, or G-L, has, we are informed, attained no small measure of commercial success.

Coal Age holds no brief for the Greene-Laucks or any other coal-carbonizing process that was ever conceived or perfected. It would appear, however, that the time is now ripe to make all possible improvements in our methods of abstracting the benefits contained in nature's storehouse of energy. The farmer who under any but exceptional circumstances would feed unthreshed wheat into the furnace of his straw-burning boiler would rightly be considered foolish. Yet American industry annually feeds millions and hundreds of millions of tons of raw coal into its furnaces, fully aware meanwhile that this coal contains byproducts of much greater value than the heat liberated by its combustion.

This yearly waste is a sin rather of omission than of commission. In the past coal has been coal; it has meant to the public, at least, only heat and the comfort that may result from or be induced by it. The perfection and commercial application of some means for abstracting the valuable byproducts from raw coal before it is burned will be welcomed by heat-users generally. Especially will this be the case if the resulting solid fuel will be more efficient in use than the substance from which it is made.

The McGraw-Hill Co. is expressing its unqualified faith in the correctness of its prognostications that prices will increase or at least remain at the present level by adding a story to its present structure. It desires to complete the work before wages and prices are higher and before labor and materials are hard to obtain.

What Is Wrong with Anthracite Pea Coal?

PEA coal is a drug on the domestic market, and operators are realizing that the situation is fast becoming serious. All the other sizes of anthracite are absorbed as quickly as they are produced, with many orders for stove coal going unfilled, but pea coal continues to accumulate. Probably the lack of demand for this size is more troublesome to the independent operators, who because they have no storage facilities for the accommodation of their surplus output are confronted with heavy demurrage bills on the coal before it can be moved from the mines. As a result much of it is usually sold at a loss. Of course, it is possible for the larger companies to run their surplus into storage yards; but this proves to be an expensive proceeding, as the cost for the extra handling to and from the yard mounts up rapidly.

There are two main reasons for the existence of the present condition. First, the operators themselves have spoiled, if not ruined, the pea-coal market by shipping during the past two years a size that more nearly resembled buckwheat than pea. Of course, it may be said that during the war they were encouraged by the fuel authorities to increase the percentage of buckwheat, but now that the war is over the operators should at least size the coal on the pre-war basis. Dealers report that their trade will simply not have the coal in its present condition. The operators spent much time in building up a domestic trade on pea coal, as for many years it was considered nothing more than a steam size and was sold at a low price for that purpose. In order to take up the surplus production of this size a domestic trade was built up in the eastern market.

The second reason for the objections coming from consumers is that the difference in price between pea and nut, the next larger size, is so small that the consumer, from the standpoint of economy alone, is coming more and more to prefer the larger size.

The market is rapidly approaching a break on pea coal, and the dealers are holding off in the anticipation of being able to procure this coal for storage at a much lower price than now prevails. Inasmuch as the mines cannot operate without producing this size, it would seem that the wisest course for the operators to pursue would be to reduce the price of pea coal from $4.80 to, say, $4.20 per ton, which would establish a ratio of $2 between that size and nut coal, and thus make it more attractive to the consumer. We know that the operators have been viewing the pea-coal situation with much alarm, and it would not be at all surprising if some action were taken soon; but at the same time the operators should see to it that the old-time preparation, so far as size is concerned, is restored.

Price reductionists have delayed house construction so that it is doubtful whether this winter we will have shelter for the public and schools for our scholars. "He kept us out of excess prices" is a slogan like "He kept us out of war." We pay for it sooner or later. When we pay we pay double for the delay.

Were They Fools or Wise?

TOO MUCH has been said of the services of labor and capital during the World War. No sacrifice of effort and of resources can compare with the sacrifices—financial as well as personal—of those who fought for a dollar a day and, while risking their lives, also during the period of conflict, surrendered their chances to lay by a competence for old age and wedded responsibilities. Labor and capital have again an opportunity in the Fifth Loan to prove that the war in a degree was won not alone by the heroic soldiers, but by the provident sacrifice of those who stayed at home. By refusing to place on the altar a money sacrifice to meet the greater offering that our boys so unhesitatingly made, we are in effect saying that they were fools to surrender so much for liberty and justice.

A living wage cannot be guaranteed. One might as well determine arbitrarily how much an acre of ground should produce by inquiring how much the owner of the land needs to get from it in order to make a living. Given, however, efficiency of labor and capital and steady work, there is absolute assurance that a living wage and more than a living wage for every normal person can be obtained even without guarantees. What the worker really wants is not as much as will enable him to live, but as much as he can earn.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

In the anthracite region the old pressure to induce the mine workers to work on holidays and holy days is being resumed. Naturally the men resent it after a period of idleness and colliery closing. The operators will, of course, receive what blame is to be borne, though the really guilty party is the buyer of coal. He talked lower price and waited for it and at the last moment put in his orders.

He has a righteous indignation that the orders are not filled as soon as filed. He cannot see why he should pay the extra dime, seeing that his order was put in before the increased price went into effect. The very purpose of the differential is to spread buying and to promote a steadying of the labor demand. Why should he expect that a delayed order should be given the concession granted to one delivered more promptly?

If there had been no advantage this year in placing the order before Apr. 30 all the orders would have come in on that date, and the mine workers would have been idle throughout the month of April except where some individual might have been compelled to buy coal to finish out the winter. The differential is of value only as it serves to maintain steady work, and it should always be interpreted so as to promote that result.

WHY SHORTEN HOURS WHEN ORDERS ARE UNFILLED?

The rush of orders, let us hope, will end, in the anthracite region, the agitation for shorter days and shorter weeks. The plan never had any applicability to the anthracite region, where, working steadily, it is barely possible to get out the coal the nation demands. It is to be expected that soon a rush will begin in the bituminous region also, for the slow time worked hitherto makes the possibility of future activity quite bright.

The Philadelphia & Reading Coal and Iron Co. has notified the miners that, as serious accidents have arisen from gas being set off by smokers, no smoking in their mines will be allowed.

A number of apprentice boys and several machinists employed in the Drifton shops of the Lehigh Valley Coal Co. were recently "suspended indefinitely" for their part in organizing a shop union.

At the mines of the Potter Coal Co., Coral, Indiana County, Pennsylvania, the mine workers have been on strike for some time to enforce the recognition of the union, despite the fact that the wages in effect at the Potter Coal Co.'s mines are higher than union wages.

MILITIA QUELLING MINE RIOT AT LINTON, IND.

On Apr. 28 the authorities of Linton, Greene County, Indiana, appealed to the Governor for troops to quell a riot said to have been the outcome of a strike of workers at that place. He dispatched one company of militia. Another company is being mobilized at Terre Haute for similar service.

The strike of the coal workers in Kansas, Arkansas and Oklahoma fields was extended by Alexander Howat, president of District No. 14, into Missouri, on Apr. 18, when that labor leader declared a strike in the mine of the Liberty Coal Co. at Appleton City, Mo. About 6000 men are now involved.

The mine workers in Nova Scotia were to vote on the five-day week on Apr. 22. The result of the vote is not yet known. The executive board voted $500 for the relief of unemployed mine workers in Cumberland, where three mines are closed down. The board also passed a resolution at the Glace Bay meeting calling on the Federal Government of Canada to provide ships to replace those commandeered for the use of Great Britain. According to the mine leaders Great Britain has 20 or 30 coal carriers built by the Canadian Government. The use of these ships by the British Shipping Board interferes with the shipment of coal from Nova Scotia. The board advocates the payment of subsidies to Canadian shipping interests engaged in such coal trade, if that be necessary to reëstablish the St. Lawrence market or to transport the coal to New England or South America.

The mine workers of Nova Scotia are not yet members of the United Mine Workers of America but the transfer from the Amalgamated Mine Workers of Nova Scotia to the international union will soon be effected. The New Brunswick mine workers have also applied for permission to join the United Mine Workers of America. It is expected that Nova Scotia and New Brunswick will form together District No. 26.

In Upper Silesia the mine workers have decided, as a result of the prerogatives given them, to oust a half a dozen of the managers and directors of some of the largest Silesian mines. Among those thus summarily removed are Herr Vogl, one of Germany's wealthiest men. He is a director of Prince Henkel Bon Donnermark's properties.

Anthracite Region—"Full Speed Ahead"

Mine managers in the anthracite region are much concerned over the coming labor shortage. Many foreigners are planning to return to Europe. The conditions obtaining in the mother countries seem in no way to abate their ardor to return. The departure of these men from the anthracite region will result in a shortage of inside labor next winter when labor is usually extremely hard to get.

Nearly all the collieries of the Lehigh region were idle on Good Friday and Easter Monday. The Lehigh Valley Coal Co., which has just resumed a full-time schedule, requested their men to work on the Easter holidays, but the request was unheeded.

Short Strike at Vesta Coal Co's Mines

Some time ago the miners at Vesta Mine No. 5, Vestaburg, Washington County, Pennsylvania, went out on strike, the ostensible reason being that a one-legged man was refused a house. He had lost his leg in the employ of the company, had received compensation, had left the employment of the company, and accepted a job elsewhere. When he returned, he thought he was entitled to rent a house of the company. In that field houses are very scarce, and persons may consider themselves fortunate if they are able to secure a passable good boarding place, a private house not being procurable. Besides this reason a number of other reasons were given for excluding him. Probably the real reason was the strength of Bolshevism among the Russian miners at that mine. They are very active and not as well educated as they might be. Many of them really believed that the time had arrived for them to take over the active working of the mine. However the trouble was amicably settled, and the men returned to work.

When pay day arrived their statements showed that they were fined a dollar a day for each day they were on strike, or four dollars each. All the mines of the company then went on a sympathy strike for the return of the four dollars which each man had been fined.

They did this against the direct warning of the district officers of the union. After staying out about ten days they voted to return to work. Neither the district officers, nor the international would support the strike. They openly declared that the men were in the wrong. The strikers concluded they did not want to fight the district, the inter-

national officers of the United Mine Workers of America, as well as the coal company, and they went back to work.

It was unofficially stated that the men who went out on the sympathy strike would be fined only two dollars, as that was all the mines would have worked in the religious season during which the strike occurred. The conservative, and English-speaking miners were opposed to the strike from the start, but were outvoted by the foreigners. The company had plenty of coal in stock, the miners wanted a holiday, the strike has been amicably settled, so probably everybody is well satisfied.

Struck to Have Two Men Ousted

About 100 miners employed in the mines at Kaymoor, in the New River field, Fayette County, West Virginia, were on strike for a few days last week, quitting work when the company by whom they are employed refused to discharge two of their fellow workers, whose discharge the miners insisted upon. Not deeming there was sufficient cause for the discharge of the two employees, the company refused to accede to the request for their discharge. After being out on strike for a few days the miners were ordered back to work by international officials of the United Mine Workers' organization.

Bower, W. Va., Field Is Organized

The Bower field in Braxton County, West Virginia, has been organized by the United Mine Workers of America and will be included within the jurisdiction of District No. 17, of which F. C. Keeney is president and Fred Mooney, secretary. Locals have been organized in this field at Bower, Copen, and Copen Creek by Board Member Nick Aeill. A wage scale has been agreed upon and contracts between the companies and the mine workers have been signed. The mines at Copen and Bower are operated by the West Virginia Coal & Coke Company. The Bower field is on the Coal and Coke Railroad and is sometimes placed in the Fairmont field. It lies about midway between Charleston and Fairmont.

The union made an effort during the summer of 1917 to organize all the mines in that field, but the coal companies which were operating the mines in that region at that time resisted the efforts of the organization. At one point in the field several shooting affrays occurred, and for a time bad blood existed between the organization officials and those of the company, it being necessary to call out three members of the special deputy sheriff's force to preserve order. The story printed a few days ago in a labor paper to the effect that the first attempt to organize the field was a failure because of the interference of state guards is wholly untrue, as the state police were at all times neutral.

Unwilling To Hear Unsubstantiated Claims

Further hearings have been held in the New River field by Judge Allison O. Smith, representing the United States Fuel Administration, for the purpose of adjudicating claims made by a large number of mine workers in connection with the advance of $1.40 allowed to monthly men. The hearings were held by Judge Smith at Stamford on Apr. 7 and 8. In all there were about 66 cases for Judge Smith to settle when the hearing commenced.

Even Mine Workers' Commissioner Dwyer, representing the operators, declares that a large number of mine workers have filed claims for back pay without first comprehending the terms of the advance and that consequently there is no ground for some of the claims, but nevertheless it has been necessary to look into all of them.

However, in order to expedite further consideration of claims, Umpire Smith has directed Commissioner T. L. Lewis, representing the operators, and Commissioner Dwyer, representing the miners, to investigate all claims in the New River and Winding Gulf districts not heretofore adjudicated, submitting to him only such claims as cannot otherwise be agreed upon.

Miners Insist on Fair Coal Prices

Declaring that the wages of the miner are too low and that a cut in the price of coal at the present time would further affect the wage scale, the executive board of District 11, United Mine Workers of America, has taken steps to oppose the reduction of the price of coal to railroads, and a letter announcing the board's stand has been sent to W. D. Hines, director general of railroads. The board declared that a reduction to railroads would prompt the public to ask also for lower rates, which, it is said, would affect the miners' pay.

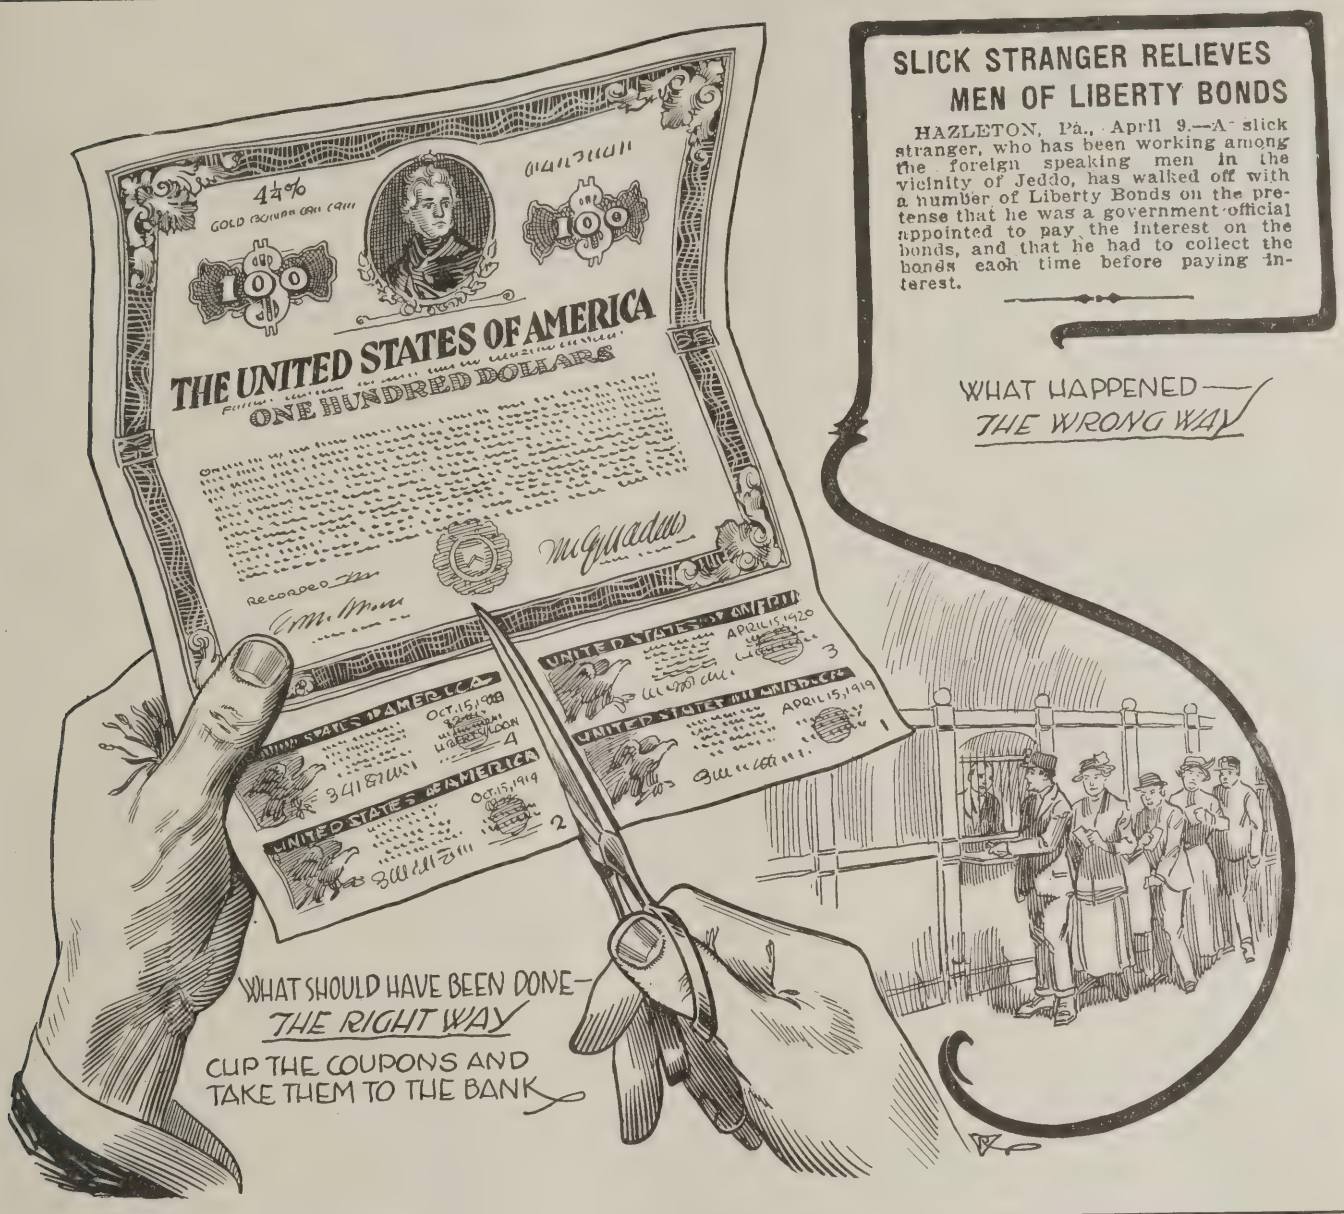
A joint statement was made by President Ed Stewart and Secretary William Mitch of the board, as follows:

"At the board meeting, the question of the reduction in the price of coal to the Railroad Administration was brought before that body. A stand was taken that this board would oppose a reduction in the price of coal brought by the railroads, and a letter announcing this was sent to Director General Hines.

"The wage scale of the miners is absolutely too low. If the railroads get a reduction in the price of coal the public will be prompted to ask for a lower price than the operators are in a position to give. If a lower rate is granted, it would mean that the miner would suffer. By this, it should not be taken to mean that the miners are encouraging profiteering. They favor only a fair price for coal, but it is a fact that many mines are merely breaking even and not making a profit."

The mine workers are determined that fair prices shall be conceded to the operators, for they well know that there is no advantage to them to deal with a bankrupt, or near bankrupt, concern. Such a corporation must inevitably take risks in the safety and treatment of its employees or go out of business. The mine worker recently has been noting that his union is formed not so much to deal with the operator as with the consumer. He is beginning to realize and acknowledge that his interests are identical with those of the operator. In consequence a new alignment is insensibly forming.

Miners Question "One Big Canadian Union"



At a recent labor convention held at Calgary, Alberta, the approval of that province was registered in favor of the proposal that Canadian workmen should organize "One Big Canadian Union" and withdraw from affiliation with the American Federation of Labor, which has its headquarters and the bulk of its membership in the United States.

The idea is not meeting with complete endorsement, as is evidenced by the observations of David Rees, international organizer of the United Mine Workers of America, who is an old coal miner and closely in touch with the coal miners' unions in British Columbia and Alberta. He says, in part:

"There is no doubt in my mind that the Western Conference should have done that for which it was called together—that is, it should have outlined a more progressive policy for the Trades and Labor Council of Canada. We find that in centers like Toronto, Montreal and in other parts of the East the labor people are clamoring for a change. Consequently, had the Western Congress outlined its policy it could well have hoped to have had the Eastern labor men working unitedly with it on the occasion of the next Trades Congress at Hamilton, Ont., next September."

Recently an Industrial Commission was appointed to investigate the relations between capital and labor throughout the Dominion of Canada. G. D. Robertson, the Minister of Labor, has announced that the question of the labor situation in the mines of British Columbia will be tackled first. The coal-mine workers are bitterly opposed to the appointment of T. Moore, president of the Trades and Labor Congress, and I. W. Bruce as members of the commission representing labor. The Fernie mine workers' leaders have been telegraphing the Minister of Labor and Dr. Bonnell, the member of Parliament for the district, demanding that these appointments be reconsidered.

Simplest Thing in the World To Cut Your Liberty Bond Coupons

CUT OFF your coupons as they become due and get your money for them from the bank or from the company for which you work. Each coupon shows when the payment of your interest is due from the Government and how much the interest is. Keep hold of your bond, don't part with it till you sell it. Cut off only such coupons as are due. If you can't tell which are due, ask a banker or the clerk at the company store. Don't do business with complete strangers from outside your home town, no matter how smoothly they talk.

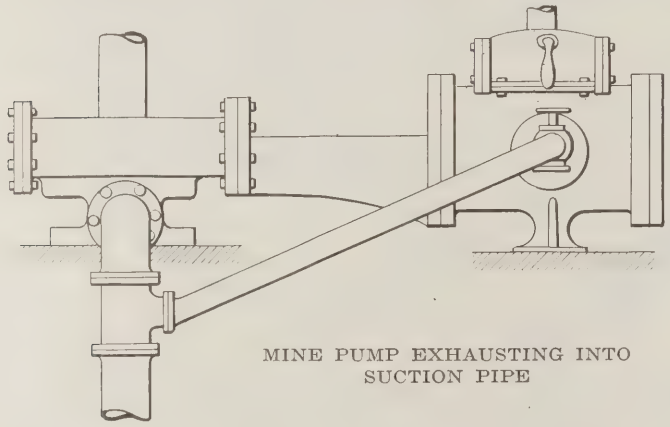
DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Calculating Depth of Shaft

The following algebraic solution has been offered by two contributors, regarding the problem presented in *Coal Age*, Mar. 6, p. 464, in which the depth of the shaft is calculated from its width and the amount a plumb-bob rises when swung from one side to the opposite side of the shaft.

In the case mentioned, the width of the shaft was 20 ft. and the plumb-bob rose 6 ft. when swung to the opposite side. In the solutions offered, x = depth of shaft. Then,



$$x^2 = (x - 6)^2 + 20^2$$
$$x^2 = x^2 - 12x + 36 \times 400$$
$$12x = 436$$
$$x = 36\tfrac{1}{3} \text{ ft., or } 36 \text{ ft. } 4 \text{ in.}$$

Exhaust from Steam Pump

Letter No. 1—In answer to the inquiry of "Assistant Superintendent," *Coal Age*, Mar. 20, p. 549, in regard to turning the exhaust steam from a mine pump into the suction or the discharge line of the pump, let me say that my experience has taught me that much benefit can be derived from exhausting into the suction pipe.

In my own practice, I have adopted this plan many times, and it has not only made it possible to get rid

MINE PUMP EXHAUSTING INTO SUCTION PIPE

of the annoyance of the steam exhausted into the mine entries, but I have found that it decreases the back pressure on the steam-end of the pump, and the same amount of water can be pumped with a lower steam pressure than when exhausting into the atmosphere.

On the other hand, I can see nothing but trouble ahead should the exhaust be turned into the discharge pipe. I have never seen that done or tried to do it myself, but the plan does not appeal to me as being practical, while the other scheme has always worked successfully.

One precaution, however, it is always necessary to observe. The engine must never be permitted to exhaust into the suction pipe, until after the pump is in full operation. Should the exhaust be turned into the empty suction pipe, before the pump has commenced to draw its water, the pipe would become heated and the pump would not start. A three-way valve must be provided that will permit the engine to exhaust into the atmosphere when starting the pump. Then, after the pump is running, this valve should be turned so that the engine will exhaust into the suction pipe, where the steam will be immediately condensed and pumped to the surface as water.

I have attempted to show in the accompanying sketch the connection between the steam end of the pump and the suction pipe. As shown in the figure, the three-way valve is located on the horizontal arm of the pipe attached to the exhaust nozzle of the pump. There is also provided a short nozzle for exhausting into the atmosphere when starting a pump.

SAMUEL MCKAY, Supt.,
Burgettstown, Penn. Harmon Creek Coal Co.

Letter No. 2—Kindly permit me to present a few comments, in addition to what has already been offered in reply to the inquiry regarding the proper disposal of the steam exhausted from a mine pump.

The inquiry does not state the size of the Cameron pump in question; but, judging from the fact that mention is made of exhausting the steam into a barrel, I would assume that the pump is a small one. This being the case, it is not to be expected that it would be desirable to go into great expense, in the way of making alterations required to produce any material change in operation. If no change is to be made in the piping arrangements about the best plan that could be adopted would be to conduct the exhaust directly into the sump.

EXHAUSTING INTO THE COLUMN PIPE WOULD CERTAINLY PROVE A FAILURE

In regard to exhausting into the column pipe into which the pump is discharging, it can be stated with certainty that this would not be successful when pumping against a head of 25 or 30 ft. or more, as the back pressure opposing the exhaust would effectually counterbalance any advantage that would arise by reason of getting rid of the exhaust steam.

On the other hand, assuming that it is worth while to make changes in the installation, I would advise conducting the exhaust steam directly into the suction line of the pump. In doing this, let me suggest that the matter should be referred to some reliable pump manufacturer for their advice. In that case, all necessary details should be submitted, in order to permit him to act intelligently. Preferably, the proposition should be submitted to the manufacturer of the pump in question, who will be more familiar with its construction and requirements.

The arrangement will differ with almost every type of pump; but, in general, it may be stated that the exhaust steam entering the suction line will result in a condensing action and give a higher vacuum gage, whereby the speed and capacity of the pump will be in-

creased, the pump then discharging a larger quantity of water, per pound of steam consumed. With a properly designed nozzle, the efficiency of the pump will be increased.

In this connection, however, it should be remembered that the temperature of the water entering the pump will be raised somewhat, which will increase the corrosive action if the water is at all acid. The effect of this corrosive action on the pump barrel, plungers, valve seats, valves and column lines must be carefully noted to ascertain if the advantage to be gained will offset the injury that will be done to the equipment.

Turning the water into the sump will produce the same effect, as far as getting rid of the steam is concerned, but will not give the increased advantage due to the higher vacuum gage produced when exhausting into the suction pipe. Where the mine water is very acid I would not recommend the plan of exhausting into the suction pipe. If possible, in such case, turn the exhaust into the sump, or into some abandoned airway or conduct it at once to the surface.

Scranton, Penn. SUPERINTENDENT.

Gravity-Plane Haulage

Letter No. 2—Referring to the letter by "Wire Rope," *Coal Age*, Mar. 6, p. 459, responding to an inquiry regarding a proposed gravity-plane haulage, which appeared in the issue of Jan. 2, p. 32, allow me to suggest that it would be interesting if the writer of that letter would adduce figures to prove the superiority of the aërial tramway that he advises installing in place of the gravity incline proposed in the inquiry. His reference to the cost of the wire rope required for the operation of the incline seems to point to that factor as determining his choice. It would be instructive if he would give us some idea as to the probable cost of rope for his aërial tramway.

Regarding the question of space available for landing 25-car trips, since no mention is made in the inquiry of any unfavorable conditions, it is natural to assume that this question has been duly considered by the superintendent making the inquiry and that proper landing space can be provided. Let me add, also, that in remarking favorably on this proposed aërial tramway (p. 459), the editor should have gone more fully into the matter than he did and explained the reason for his conclusions in respect to the proposition.

Gravity Tramroad vs. Aerial Tram or Cableway

Although the inquiry does not state what tonnage it is desired to handle from the mine to the tipple, it would be further interesting to know what tonnage it would be possible to handle over an aërial tramway; and it is to be hoped that "Wire Rope" will give us his estimate of the capacity of such an equipment. Knowledge of the experience of one or two individuals, with this means of transportation, makes me skeptical, to a degree, of its advisability.

Personally, I can see no reason why it should be impossible to operate a tramroad such as was proposed in the inquiry of this superintendent, if ample provision is made in the original plant, in respect to factors of safety in hoisting and in relation to rope, drawbars, couplings, shackles, etc. Even if it can be shown to be impracticable to run 25-car trips on this incline, I believe it can be successfully operated by the use of a gunboat or monitor.

The reply of the editor, following the inquiry (page 32) suggests the use of a "barney" to counterbalance the weight of the descending loaded trip, the weight of the barney being yet sufficient to draw an empty trip of the same number of cars up the incline. May I inquire what advantage would be derived from the use of this barney, and ask to know the experience on which his suggestion is based.

Long and Steep Gravity Plane Controlled by Water-Cooled Air Brake

Referring to the statement of "wire rope," who says he has never seen an incline operated by gravity on as large a scale as the one proposed in this inquiry, let me say that this fact does not prove the proposition to be impracticable. I have in mind a gravity tramway that is 5800 ft. long and contains about 2500 ft. of 20 per cent. grade. Trips of 17 cars are operated by gravity on this tramway. The empty cars weigh 3250 lb., each, and carry an average of 3.6 tons of coal. Occasionally, a car will be loaded with 5 tons of coal.

Taking the first figure given, which is a fair average capacity for these cars, a loaded trip of 17 cars will carry 122,400 lb. of coal and have a total weight of 177,650 lb. A 1½-in., 6-strand, 19-wire Roebling, blue-center, rope is used on this incline. Tandem, slip-ring drums are installed at the head of the incline to lower the cars. The drums are equipped with internal water-cooled brakes actuated by air compressed by the operation of the machine.

This incline has handled an average of 2300 tons of coal per day, month in and month out. I know of several other gravity trams where the conditions are probably as severe as those involved in this inquiry. Also, allow me to ask why the editor suggested a 1¼-in. cast-steel, 6-strand, 7-wire, haulage rope for this tramway.

R. M. MAGRAW, Gen. Supt.,
Hiawatha, Utah. United States Fuel Co.

In the experience of the editor, the advisability of installing an aërial cableway, for the transportation of minerals from a mine opening located at a considerable elevation above the tipple where the output is to be loaded for shipment, is based on the following items: Ease and rapidity of installation and lower first-cost of equipment; continuous and uniform transportation of output from mine to tipple; liability to delays caused by derailment, making up of trips, weather conditions, etc., reduced to a minimum; minimum cost of upkeep by reason of eliminating track repairs; avoidance of risks due to runaway cars on incline; and less wear and tear of mine cars, due to hoisting on steep inclines. Where the arrangements for loading the buckets are made automatic, no system of inclined-plane haulage can equal the tonnage capacity of an aërial cableway, and nothing is more convenient or safer in its operation.

The suggestion of employing a barney is made for the purpose of reducing the margin between the weight of the descending loaded and ascending empty trips and thereby lessening the duty of the brake required to control the speed of the drum sufficiently to insure safety. This is based on an experience had in the operation of a gravity plane in the far west (1884) and the later observation of the working of steep inclines in the middle Anthracite Valley (Penn.).

Regarding the suggested 1¼-in., cast-steel, 6-strand, 7-wire, haulage rope (page 459), it will be noted that,

making allowance for the added weight of the rope, the estimated diameter of this rope was finally increased to $1\frac{3}{8}$ inches.

Mining practice assumes that a 6-strand 7-wire haulage rope gives better service on an incline than a 6-strand, 19-wire, hoisting rope, owing to its greater resistance to abrasion, the individual wires of the former being larger than those of the latter, which also gives greater rigidity to the rope for haulage purposes.

It should be stated, here, that it is, of course, possible to lower any weight of loaded trip on an incline having any steep grade whatsoever, provided that it is possible to control the descent of the loaded cars with safety. Numerous instances are on record, however, of steep inclines operated by gravity that have been the scene of serious and fatal accidents, owing to the failure of the brake to control the descent of the loaded trip. For this reason, it is always practicable to govern the number of cars hauled on such an incline, so as to avoid this risk by establishing a safe margin between the weight of the loaded and empty trips; or by employing a barney as a go-between on such inclines.

Correct Accounting

Letter No. 2—Referring to the letter of Thomas T. Brewster, which appearedin *Coal Age*, Mar. 13, p. 501, it appears to me that the view he takes of the proper accounting of mine equipment and supplies is radically wrong. While it may be admitted that there would result a slight saving in the matter of accounting, if such minor items as fall under the head of supplies for immediate use were to be charged at once to operating expense, the same rule will not apply to actual equipment and to many other supplies that must be carried in stock in order to avoid the delay that would result if it was necessary to send for such supplies every time they were needed.

Let me illustrate by assuming that the inventory for the year 1918 showed, say three locomotives, five pumps, 20,000 ft. copper wire, eac., and the following year, there sis purchased one locomotive, two pumps, 2000 ft. of wire, or other similar equipment. It stands to reason that the inventory for 1919 will then show four locomotives, seven pumps, 22,000 ft. copper wire, etc. Now, as stated in the editorial note that follows Mr. Brewster's letter, a suitable valuation should be attached to each item of the inventory, and these values will decrease year by year, according to the life of each article of equipment. The total valuation, however, shown by the inventory may be much increased by the purchases for that year.

Equipment and Stock Supplies Not Expense

My idea is that much of the equipment and material purchased for the operation of a mine will last for 10, 15 or 20 years and be a part of the entire plant. Evidently, it would be wrong to charge the cost of such items to the operating expense of the single year when they were purchased. It is my opinion that all new material, such as wire, tee rails, motors, pumps and other machinery, should be charged either to the equipment or the stock account. Then, when supplies are taken from the supply room for use in the mine, they should be charged to operating expense. Only in this way can a correct account of the expense of running a mine be kept for each year.

When a piece of equipment has become so badly worn that it is no longer of use and is discarded, it is cast aside or, as we say, "scrapped," but the balance sheet for the year will show the net loss or gain. At the end of each fiscal year, the balance of the equipment account must be made to conform to the inventoried valuation of equipment by crediting the former account with an entry that is then charged to the profit-and-loss account, on the ledger. In closing, let me say that I would be very sorry to have my operating expense account charged with material that was not used in the operation of the mine for that year and which my son or grandson might use in years to come.

Burgettstown, Penn. ACCOUNTANT.

A Modified Longwall System

Letter No. 2—Referring to the interesting article of F. A. Pocock, *Coal Age*, Feb. 27, p. 395, regarding the 5-entry, panel-longwall system he has presented for the working of a 3-ft. seam of coal such as the Freeport or Kittanning series, let me say that it would seem that the author of the article has concentrated his entire thought on producing a method that would insure the largest possible output in the shortest possible time. Whether or not this plan can be worked out in detail, in practice, remains to be seen.

There are, to my mind, some objectionable features respecting the details given by Mr. Pocock, in the working out of the system he presents. These objections suggest themselves to me as the result of a long experience in longwall mining, in Scotland and England and, later, in Pennsylvania, where I had to contend with strata and conditions similar to those he has described.

Brief Survey of the Proposition

If I understand the proposition correctly, it is proposed to start the development by driving a five-entry system of main headings, and turn five-entry crossheadings to the right and left of these, leaving 600-ft. pillars between each set of crossheadings. As the work proceeds, the plan appears to be to work out each alternate pillar on each side of the main heading, on the advancing system, by starting a longwall conveyor face, after leaving a solid pillar of coal 300 ft. thick for the protection of the main headings.

It is proposed to use two conveyors on each face, the length of each conveyor being 100 yd. As each advancing longwall face reaches the boundary, the succeeding alternate pillars are then to be drawn back in a similar manner, on the retreating system. The coal is to be undercut to a depth of 10 ft., using an arcwall machine for that purpose.

My first objection refers to the proper support of the roof, which is described as not being self-supporting over a considerable area. Let me assume, for instance, that the conveyor requires a space of 2 ft. 6 in., and the cutting machine, another 3 ft., while the depth of undercut is 10 ft. The best support that can be given, in that case, is to set posts within a foot of the coal and immediately behind the machine as it moves along the face.

Now, when the machine has finished one cut across the face, the area of roof left unsupported over the coal that is undercut will be, at the least, $(10 \times 600) \div 9 = 666$ sq.yd. The fact that this roof must remain unsupported until the coal has been loaded out makes

it a question in my mind if a very serious collapse of the roof will not take place. It seems to me that it would be a miracle if an accident did not follow.

Another objection that occurs to me relates to the proposed deep undercutting of the coal. I believe that any person who has had much experience in longwall machine mining will agree with me that at least some of this coal will be wedged practically solid and will have to be blasted before it can be loaded out.

It is also a question whether all of the coal from a 10-ft. mining can be cleared from the face, each day, in time to allow packs being formed at each end of the face and the necessary chocks built and the conveyor moved forward. Mr. Pocock has even suggested three shifts a day, the machine making a 10-ft. cut in each shift, which is practically impossible of accomplishment.

Ten-foot Cut Not Safe in Longwall Work

Again, it is my belief that it will require twice the manual labor to load a 10-ft. cut onto the conveyor than would be required with a 5-ft. cut; and the results will not show the same tonnage per man. After the first 5 ft. of the 10-ft. undercut has been loaded out, the difficulty of handling the remaining 5 ft. would suggest the necessity of, first, moving the conveyor forward and drawing and resetting posts and cribs, all of which would increase the time for the roof to settle and bind the coal that remains unloaded.

I do not wish to be understood, however, as holding that the proposed method has no good features, as my objections relate only to the details of working. Let me say that, in my opinion, better results would be obtained by pushing the development until a number of sections can be opened that would give the same output with a 5-ft. undercut in the longwall faces.

Such a plan would certainly be more favorable to the support of the roof and avoid the risk of the undermined coal being held fast by the settlement that will naturally take place when a 10-ft. cut is made in the face. Let me suggest, further, that special care must be taken to insure the complete withdrawal of all props and other timber supports in the waste, always leaving three rows of staggered props behind the conveyor.

The idea of securing a large output in the shortest possible time is all right if the method adopted is such as to insure the safety of the men and the property. Too great haste in gaining a large output, in coal mining, will generally involve future loss, as was the case when I assumed charge as general superintendent of a mine in Derbyshire, England, where my predecessor had worked out the coal too close to the outcrop and brought on a heavy squeeze, besides permitting the surface water to enter the mine.

McKeesport, Penn. Andrew Orr Bain.

Efficiency in Firebossing

Letter No. 14—A long experience in firebossing in mines, followed by a period of mine foremanship and a later service as state mine inspector, has interested me deeply in the discussion of the development of the highest efficiency in our firebosses.

I have come to realize to the fullest extent that all of these official positions carry with them great responsibilities. However, in respect to the safety and protection of life, I am convinced that the greatest responsibilities rest on every fireboss who attempts to discharge his duties faithfully to the state and to the men employed in the mine.

There are many qualifications that an efficient fireboss must possess, but the most essental are: practical experience, habits of industry, honesty and faithfulness in the performance of duty. He must also be resourceful and calculating, taking nothing for granted, but investigating every situation for himself and to his own satisfaction.

It is a matter of regret that too many miners who hold fireboss certificates, or mine-foreman certificates with fireboss privileges, seem to think that these certificates are the only qualifications they need, and make no further effort to increase their efficiency by diligent study. They forget or do not realize that the knowledge gained by such study will not only fit them for the better performance of their work, but will give them a quicker perception and enable them to grasp a situation more promptly and act more quickly and judiciously in an emergency.

Every fireboss must have a high estimate of human life. He must realize that the lives of the men employed in the mine are in his keeping. He should be fully awake to the great responsibility resting on him in his official position, and his attitude and bearing should be such that he will command the highest respect and confidence, both of the men in his charge and the company who employs him.

Full Control of Ventilation with Fireboss

Referring to the excellent letter of W. H. Luxton, *Coal Age*, Mar. 27, p. 590, I want to indorse the suggestion he makes that "the ventilation of the mine should be entirely in the charge of the fireboss." In my opinion, the fireboss should be the final judge as to whether or not the ventilation is sufficient or adequate in the section of the mine of which he has charge.

Personally, I would not accept the position of fireboss in a gassy mine, unless I was given full control of the ventilation. Neither would I undertake to perform the duties of that position in a mine where the fireboss was regarded as a "necessary evil," and made subordinate to the foreman in every respect.

For a number of years, I was employed as fireboss in a very gassy and dusty mine where I had full charge of the ventilation and gave such instructions to the foreman and bratticemen as, in my opinion, were required to conduct the air to those parts of the mine where it was most needed for the safety of the men. I ranked as foreman, in the absence of that official. If a slate fall occurred on a haulage road, at a time when the foreman was in some remote part of the mine, I at once assumed charge of the situation and started men to clear up the fall.

In that mine, when making my morning rounds it was my habit to note down any slate falls on the roads, stating how the slate would have to be handled—whether gobbed or loaded out, and how much time would be required for the work. I would give the number, size and length of timbers needed and report these items to the foreman. Besides that, I was able to inform him what was the prospect for a good day's run, stating where loose coal was plentiful and where shots had failed to break down the coal.

This information always enabled the foreman to properly distribute the drivers, and greatly expedited the work in the mine. It appears to me that any effi-

cient fireboss will do the same, reporting where dangerous conditions exist on the roads or in the rooms, and stating what is required to make such places safe. In fact, all unusual conditions should be reported to the foreman, by the fireboss on his return to the shaft bottom or the mine entrance.

Allow me to conclude this letter by saying that a fireboss should work in harmony and in conjunction with the mine foreman in every instance, having in view the safety of the men and the successful operation of the mine. At the same time, it is my belief that the line should be drawn when it comes to making it a part of the duty of a fireboss, even in small mines, to busy himself with pumps, tracklaying, setting timbers, and various things of a similar nature, as was suggested by Edward H. Coxe, in his letter, Jan. 23, p. 199. Mr. Coxe might just as well have used his imagination farther, and, perhaps, he would have found that mine foremen and superintendents of little mines have about as much time to devote to such work and the laying of track, as firebosses.

JOHN ROSE,
Dayton, Tenn. Former District Mine Inspector.

Letter No. 15—So many good points have been brought out in the discussion regarding "efficiency in firebossing," that it is difficult to say which is of the greatest importance. However, the most salient point that has developed appears to be the question of whether the fireboss, in addition to the duties required of him in making the examination of the mine in the morning and looking after the safety of the men and giving them needed instruction while at work in their places, shall do such other work as digging coal, ditching, tracklaying, timbering and cleaning up falls.

While I believe the disposition of a good fireboss should be such as to make him generally useful (and this would certainly add to his efficiency in most mines) too much depends on the need of his keeping in close touch with the conditions existing in the mine to enable him to do much else besides, particularly if the mine is generating gas. It must be remembered that conditions, in most mines, are not so favorable that the safety of the mine, respecting gases and proper ventilation, is assured when the fireboss has completed his rounds in the morning.

In addition to making the examination of the working places, roadways and travelingways, the fireboss must often do much work in the way of putting up brattice that a shot has dislodged, before he can clear a place of gas. At times, it may happen that he is obliged to hang canvas that should have been put up by the bratticemen the day before; and, it is safe to say, that the morning examination will often prove a busy half-shift.

The Second Round of the Fireboss

The second half of a fireboss' shift will generally have to be devoted to a closer inspection of the working places, in order to see that bad roof and other dangerous conditions are removed, necessary timbers set, breakthroughs made in compliance with the law, and air-courses and travelingways cleared of all obstructions. The proper performance of these duties will generally leave him little time for the other work mentioned.

In the event of a fall blocking the track, wires down, or cars derailed, it is of course the duty of both the mine foreman and the fireboss to lend a hand and do everything possible to restore conditions and prevent delays. I have seen many good firebosses help their foremen in a way that has increased the production of the mine. Such firebosses are doing far more efficient service than when directed to perform some manual labor that can be done as well or better by other men.

There are, undoubtedly, a large number of firebosses who are responsible and dependable in respect to the reported condition of the mine as being safe for work, but the number who prove their efficiency by assisting the foreman in a way that increases the production of the mine, I believe, is not so great. Firebosses of the latter type are a valuable asset to the foreman and the company who employ them. It should not be expected, however, as some of the remarks that have been made would seem to intimate, that a mine foreman should hand over the keys of his authority to his fireboss.

Two Types of Efficiency in Firebossing

No good foreman will fail to appreciate the service rendered by a truly efficient fireboss and give him due credit for his work; but he will not waste much time with a fireboss who lacks ambition and possesses no qualifications for a higher position. A foreman is apt, at times, to keep such a fireboss busy and ask him to perform tasks that will not interfere with his regular duties in looking after the safety of the mine. Such firebosses represent one grade of efficiency. They are faithful, reliable and trusted by everyone in the mine.

Another type of efficiency is represented by the fireboss who, while just as qualified for his own particular work, possesses the knack of proving himself useful in other ways, by his success in the handling of men, expediting the work and increasing the output of coal. It is this class of men that are not satisfied to remain in the position of fireboss. Their peculiar ability is recognized, sooner or later, if not by their own company, then by others. Good men cannot be kept down.

An Example of Good Firebossing

The following incident, which I recall, illustrates exactly my idea of *efficiency in firebossing:* A young fireboss came suddenly on a gang of men cleaning up a fall. His unexpected approach interrupted their moments of leisure and the men jumped for their tools, only to discover that, as they said, "We thought you were the boss," whereupon they again resumed their pipes and attitude of leisure.

As the fall blocked off one section of the mine from which much coal was hauled, the young fireboss promptly threw off his coat and started to break some of the slate, saying as he did so, "Do you want me to tell the boss that you fellows quit?" The men were quick to observe that he made no attempt to display his authority or to assume that he was a boss, and the result was that they started at once to work and indulged in no more foolishness.

The foreman was never told of the incident; but the fireboss, it should be stated, gained the reputation of being efficient, which he richly deserved. It is a common thing for some firebosses to air their supposed grievances, but such are not the ones who are in line for promotion.

ESSEX.
Thomas, W. Va.

[This letter will close the discussion on "Efficiency in Firebossing."—Editor.]

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

Dew Point in Mine Air

Kindly explain, in the columns of *Coal Age*, at what temperature air will deposit its moisture on the roof, floor and sides of an airway in a mine. Also, please state at what temperature air will begin to absorb moisture from the mine workings. STUDENT.

Thompson, Penn.

The capacity of air to carry moisture depends on its temperature. In other words, the weight of water vapor required to saturate a cubic foot of air increases as the temperature of the air rises, but not in the same ratio. When the point of saturation of air, at any given temperature, is reached the weight of vapor contained in a cubic foot of the air is a fixed quantity. It is evident, then, that any fall of temperature when the air is saturated will result in some of the vapor being deposited as moisture. The point at which moisture begins to be deposited is called the "dew point," which varies with the temperature. The pressure or tension of vapor also changes with the temperature and must be taken from a table of saturated-vapor pressures.

Now, applying these facts to the conditions existing in mine workings, we will assume the temperature of the mine is, say 60 deg. F. The vapor pressure, at that temperature, is 0.2545 lb. per sq.in., and the corresponding absolute temperature 460 + 60 = 520 deg. F. Knowing these data, the weight of vapor saturating a cubic foot of air or space is calculated by the formula

$$w = \frac{5793 p_v}{460 + t} = \frac{5793 \times 0.2545}{520} = 2.8 \text{ gr. per cu.ft.}$$

But the outside air blowing into the mine may not be saturated and its temperature may be such that it may hold a greater or a less weight of moisture than this amount. For example, suppose the outside air has a temperature of 80 deg. F. and 60 per cent. humidity. That is to say, the air is only carrying 60 per cent. of the weight of moisture that would saturate it.

Now, when this air enters the mine and its temperature has fallen to that of the mine atmosphere (60 deg. F.), its capacity for carrying moisture is greatly lessened. The weight of moisture taken into the mine is

$$w = 0.60\left(\frac{5793 \times 0.5027}{460 + 80}\right) = 3.2 \text{ gr. per cu.ft.}$$

In making these calculations, it is necessary to refer to a table giving the saturated vapor pressures corresponding to different temperatures ("Mine Gases and Ventilation"—Beard, p. 62. Notice the saturated vapor pressure, for a temperature of 60 deg. F., is 0.2545 lb. per sq.in., while that for a pressure of 80 deg. F. is 0.5027 lb. per square inch.

In the case just cited, it is evident that the intake current, which was *dry*, on entering the mine at a temperature of 80 deg. F., carries 0.4 gr. per cu.ft. more moisture than is required for saturation at 60 deg., or the temperature of the mine workings. Assuming a current of 100,000 cu.ft. of air per min., under these conditions, the weight of water deposited in the mine as moisture would be (100,000 × 0.4) ÷ 7000 = 5.7 lb. per min., or nearly ¾ gal. a minute.

It is evident that the answer to the question—"At what temperature will moisture be deposited in a mine air?"—depends largely on the temperature and humidity of the intake air. When the intake current carries a greater weight of misture than will saturate the air at the mine temperature, the excess moisture will be deposited in the mine, but not otherwise. Air is said to be "dry" when it carries less moisture than is required for its saturation, and "wet" when any decrease of its temperature will cause a deposit of moisture; or, in other words, when the dew point is reached.

In answer to the second question, it can only be said that *dry air* will always absorb moisture from moist bodies with which it is in contact. Here, also, the temperature at which this will take place depends on the conditions previously mentioned.

Efficiency of Mine Hoist

The card taken from an engine when hoisting at a certain shaft mine showed that the indicated horsepower, or the power developed in the cylinder of the engine was 60 hp. At the time the card was taken, the engine was hoisting a load of three tons. The depth of the shaft was 148.5 ft. and it required just 30 sec. to make the hoist.

Now, neglecting the friction of the hoist, what is the efficiency of the engine? Also, what is meant by the term "compression," and what is its object?

Divernon, Ill. HOISTING ENGINEER.

To answer the first question, from the data given, it would be necessary to make no allowance for acceleration or retardation when starting and stopping the hoist, and assume that the speed of winding was 148.5 ÷ 30 = 4.95 ft. per sec. In that case, the work performed in the shaft is (3 × 2000) 4.95 × 60 = 1,728,000 ft.-lb. per min. On that basis, the efficiency of the engine is

$$\frac{1{,}728{,}000 \times 100}{60 \times 33{,}000} = 90 \text{ per cent.}$$

However, while this method gives what may be called the *average efficiency* of the hoist it is well to remember that the work in hoisting is not uniform; but, starting from zero, at the beginning of the hoist, the power expended increases to a maximum during acceleration; and decreases when retardation begins, till it again becomes zero when the hoist is finished. To estimate the efficiency of the engine under full load at maximum speed it is necessary to know the time of acceleration and retardation.

The term "compression," in engine practice, refers to the compression of the steam in the cylinder of the engine from the time the valve closes the exhaust port to the end of the stroke. The object sought is to assist in bringing the piston to rest and starting it forward on the next stroke.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Miscellaneous Questions

(Answered by Request)

Ques.—How can you tell whether or not any obstruction is in an airway or air-course that you have not passed through?

Ans.—Any unusual obstruction in an airway would be indicated by a decrease in the quantity of air passing, or an increase in the water gage, or both, for that airway or section of the mine. Assuming the power on the air remains unchanged, any obstruction in an air-course decreases the quantity of air passing and produces, at the same time, a rise in the water gage, the quantity of air varying inversely as the water gage.

Ques.—What is the rubbing surface in an airway 4 ft. high, 9 ft. wide and 1000 ft. long?

Ans.—The rubbing surface in this airway is $1000 \times 2(4 + 9) = 26{,}000$ sq.ft.

Ques.—What is the capacity of a double-acting plunger pump if the plunger is 20 in. in diameter, the stroke 40 in., and the pump is making 25 r.p.m.?

Ans.—The sectional area of a 20-in. plunger is $a = 0.7854\left(\frac{20}{12}\right)^2 = 2.182$ sq.ft. At a speed of 25 r.p.m., a single plunger makes 50 strokes a minute, and the length of stroke being 40 in. or $3\frac{1}{3}$ ft., the plunger displacement is $2.182 \times 3\frac{1}{3} \times 50 = 363\frac{2}{3}$ cu.ft. per min. Unless otherwise stated, it is customary to assume the efficiency of the water-end of a good pump as 85 per cent. of the plunger displacement, which would make the capacity $0.85 \times 363\frac{2}{3}\left(\frac{1728}{231}\right) = 2720$ gal. per min.

Ques.—What equipment is required to be kept at the mine, for the care of the injured?

Ans.—The bituminous mine law of Pennsylvania (1911), Art. 13, requires that one ambulance and at least two stretchers, together with woolen and waterproof blankets, bandages, splints, and other medical supplies shall be kept on hand and ready for immediate use in time of need, at every mine in which 50 or more persons are employed inside. The law further provides that where 90 per cent. of the workmen live within a radius of a mile from the mine, no ambulance will be required; and where two or more mines are located within a mile of each other a single ambulance is sufficient for such mines.

Ques.—What must be the sectional area of a square airway that is required to pass 50,000 cu.ft. of air per min., under a 1-in. water gage, the length of the airway, including the return, being 1 mile?

Ans.—First, write the formula expressing the pressure required to pass a given quantity of air through a given airway. Thus,

$$p = \frac{kloQ^2}{a^3}$$

For a square airway, the perimeter is four times the square root of the area; thus, $o = 4\sqrt{a}$. Then, substituting this value for the perimeter of the square airway, in the formula just given, and solving with respect to the sectional area (a), gives

$$a = \sqrt[5]{\left(\frac{4klQ^2}{5.2w.g.}\right)^2}$$

Now, substituting the values $k = 0.00000002$; $l = 5280$; $Q = 50{,}000$; $w.\ g. = 1$, we find, for the sectional area of a square airway required to pass 50,000 cu.ft. of air per min. under a water gage of 1 in.

$$a = \sqrt[5]{\left(\frac{4 \times 0.00000002 \times 5280 \times 50{,}000^2}{5.2 \times 1}\right)^2}$$

$$= 132.77 \text{ sq. ft.}$$

Each side of this airway is $\sqrt{132.77} = 11.52$ feet.

Ques.—From what source is the greatest number of accidents at the working face, and how would you endeavor to lessen or prevent them?

Ans.—The latest report of the bituminous district of Pennsylvania, states that of the 412 lives lost, in the year 1916, in the bituminous mines of the state, 227, or 55.1 per cent. of these were due to "falls of coal, slate and roof." Of this number, 159, or 70.05 per cent., were killed at the faces of rooms; 37, or 16.3 per cent., while drawing pillars; and the remaining 31, or 13.65 per cent., on the entries, airways or travelingways in the mines.

Ques.—Ignoring friction, what quantity of water will be discharged from a borehole 22 in. in diameter and 4 yd. long, under a head of 150 ft.?

Ans.—The theoretical velocity due to a head of 150 ft. is $v = \sqrt{2gh} = \sqrt{2 \times 32.16 \times 150} = 98.22$ ft. per sec., and the area of a 2-in. hole being $(0.7854 \times 2^2) \div 144 = 0.0218$ sq.ft., the quantity of water flowing from the hole will be $60 \times 98.22 \times 0.0218 \times 7.48 = 962$ gal. per min., there being 7.48 gal. in a cubic foot.

Ques.—A certain fan is running at a speed of 75 r.p.m. and producing 50,000 cu.ft. of air per min. The air current travels 10,000 ft. in its passage through the mine. Now, if the air is short-circuited so as to reduce the distance the air must travel to 500 ft., would the speed of the fan be increased or decreased? Explain why.

Ans.—Reducing the length of air travel reduces the mine resistance in the same proportion. When the resistance against which a fan is operating is reduced, the result is that a larger quantity of air will flow through the fan. But, the frictional resistance within the fan itself increases as the square of the quantity of air passing. This means a large increase in the work absorbed within the fan and lost. The result is that less power is available for turning the fan, which will run a little slower under the same steam pressure at the throttle, than it did before the air was short-circuited.

In other words, the rush of air through the fan when the mine resistance is reduced or cut out causes a loss in the power available for turning the fan, because a larger proportion of that power is absorbed in passing the air through the fan itself. The power then turning the fan being less, the speed of turning is decreased.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Italian Coal Situation

An article in the *Corriere della Sera*, Milan, Mar. 16, 1919, states that the problem of obtaining an adequate coal supply in Italy has continued to become more serious since the armistice, although it was believed that with the suspension of hostilities the solution would gradually become easier. In order that the actual state of affairs may be well understood, it seems opportune to furnish certain data regarding the year preceding the war.

In 1913 Italy imported on the average 900,000 tons of coal per month, equal to 10,800,000 tons annually—2,200,000 tons for the state railways, 200,000 for the other railways and steam trams, 700,000 for the navy and merchant marine, 1,200,000 for the gas works, and the remainder for private industry.

During the war the consumption of coal by private industry increased in some branches, such as metallurgy, and decreased in others. The total shows a progressive decrease in accordance with the decrease in the total imports of coal, due to the shortage of tonnage and to diminished production. During the war the Italian government informed the allies that the requirements of Italy should be placed at 740,000 tons, which was later reduced to 690,000 tons. There was allotted a monthly supply of only 600,000 tons, but it was only an allotment, for there was always furnished a smaller quantity—5,280,000, equal to a monthly average of 440,000 tons in 1917; 6,400,000, equal to a monthly average of about 530,000 tons in 1918. The most critical month was February, 1918, during which Italy received only 328,000 tons of coal.

Before the war, of the total exports of coal to Italy about 9,000,000 tons came from England, about 1,000,000 from Germany and Austria, about 160,000 from France, and about 90,000 from the United States. America increased its exports of coal to Italy to 300,000 tons in 1914, and to 1,742,000 in 1915. In 1916 they were 1,056,000 tons, but in 1917 they dropped to 451,000 tons. In the last period of the war they ceased almost entirely, because, in their desire to save tonnage, the allied powers decided that Italy should be supplied with coal from England in preference to America.

The armistice having come, the Italian government had the assurance of a monthly average of 800,000 tons for two months and of 1,000,000 for the succeeding months, but instead of improving the situation has become steadily worse. In November Italy received 647,000 tons of coal; in December, 472,000; in January, 439,000; in February, 502,000. In March, in all probability, Italy will not receive more than 375,000 tons.

Temporary Supplies from France

Hon. Crespi recently obtained from the interallied economic commission the concession, without any assurance for the succeeding months, of 100,000 tons of coal from the Saar Basin, from St. Etienne and Salon. This 100,000 tons will arrive naturally, by land. It is a long-flame coal, not suitable for locomotives, and will serve for other uses.

With reference to the furnishing of coal by France, it may be said that this was carried on actively from January, 1918, to January, 1919. It was agreed to by the allies, always with a view to conserving tonnage, that France should ship its coal by land and replenish its supply from England.

In 1918 Italy received 2,000,000 tons of French coal out of total imports of 6,400,000. The balance was all English. Italy only received 42,000 tons from France in January and February. All the rest was English coal.

The Importation of American Coal

A favorable prospect for the solution of the difficult problem is contained in the possibility of sending American coal to Italy. England leaves Italy entirely free to obtain supplies from this country. Some time ago we tried to establish a regular service of supply to Italy. As yet, however, the great obstacle has been the lack of ships. It was necessary that Italy should send for the coal herself, and such ships as were available were not sufficient to actually establish a regular importation. It was an absolute impossibility to do so, and it must be borne in mind that 75 per cent. of the coal exported to Italy is handled by British ships and only 25 per cent. by neutral or Italian vessels. With regard to prices, owing to the increased cost of transportation, American coal is more expensive than the English. It appears, however, that we are preparing to make considerable reductions, which will facilitate the fulfillment of the desire which exists both in Italy and America to establish a regular service of supply.

Requirements of Certain Industries

The requirements of the Italian brick manufacturers are 60,000 tons per month even for a moderate activity in the industry; the metallurgical establishments are now renewing their activity after some months of depression; the steamship lines again in operation need 30,000 tons per month; the railroads now use 240,000 tons per month, but if Italy is to restore the service as it was before the war she will need at least 300,000 tons for her railroads. The gas works, at a reasonable estimate, use 76,000 tons per month, and in the end it will be necessary to let them have 100,000 tons, without calculating the needs of the recovered territory.

Ships Will Soon Be Available For Foreign Trade

The next thirty days will find our ships available for the world's foreign markets, according to a statement given to the American Manufacturers' Export Association by John H. Rosseter, Director of Operations of the United States Shipping Board.

Mr. Rosseter, in replying to a request of the Association for information regarding the recent report to the effect that the European civilian relief program would take a great many vessels away from export trade, gave assurances that the Shipping Board is making every effort to fairly meet the extraordinary demand for American ships.

"Until the economic policies that will control international commercial interests are actually declared by the Peace Conference," said Mr. Rosseter, "America's business interest must mark time in the march the country is to take into the markets of the world. The action of the Government as far as its present shipping policy is concerned has been taken, "asserted Mr. Rosseter," for the purpose of clearing away as rapidly as possible the clouds of uncertainty that now hang over the foreign markets of the world.

"If economic reconstruction and readjustment in international affairs is to be rapid," Mr. Rosseter continued, "the business and commercial interests of the country must for a very short time continue to evidence the remarkable spirit of patience so splendidly displayed throughout the months of the war. The situation in Europe today is exceedingly precarious. It is plainly the duty of the United States to aid in removing these conditions which are impeding a rapid and quick return to normal in the country's foreign commercial affairs. With this as a guiding purpose, the Government is sending one hundred million dollars worth of foodstuffs for distribution among the starving peoples of Europe. The completion of this food program is most important. The proper solution of the great questions now before the Peace Conference depends upon its successful completion. To successfully complete it, the Government has found it absolutely necessary to devote practically every ton of its available shipping to that end. Ships that are essential in regular foreign trade routes have been assigned to the food program. The Government realizes fully what this kind of disruption to ordinary and routine trade means, but I can give the business interests of the country the utmost assurance that this condition is only temporary.

"The Shipping Board has provided not less than 1,390,000 deadweight tons of steamers for European relief during a period of three months.

"The foreign business interests of the United States," Mr. Rosseter points out, "are giving precedence to two programs—the Government's food program on the one hand and the Army program on the other. The food program is being carried out for the purpose of infusing new life into the markets of Europe, Russia and the Balkans; the Army program, which is all-important, has to do with the bringing home of our boys within the shortest possible time. Ships play an important part in both these programs. Until they are completed, America's commercial interests must make the most of a difficult situation."

When asked specifically whether the Government was withdrawing ships from commercial purposes to assign them to the two programs mentioned, Mr. Rosseter replied:

"The fact is, that the commercial interests of the country have not been given the opportunity to utilize America's new merchant fleet. Conditions from the time we entered the war up to the present moment have been such that sacrifice was the watchword of America's business men as far as foreign markets have been concerned.

"I personally believe that the next thirty days will find our ships available for the world's foreign markets, and the industries of the country will no longer be obstructed for want of tonnage. Of course, as I have pointed out, we are now taking the first real and definite step toward that object—the completion of the two shipping programs now before the Government.

"Today I can happily say we see our way clearing to carrying in United States ships the total of all the European relief demands, and we can now turn our attention and our surplus ships to commercial needs."

Foreign Coal Trade Opportunity

An American consular officer reports that a man in Switzerland wishes to represent an American coal firm. References are furnished. Those interested may obtain the name and address by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or any of its branches. Refer to Number 29180.

Increased Cost of Fuel in Argentina

Supplies of all kinds have increased tremendously in price in Argentina since the beginning of the war and have been hard to obtain at any price; but the increase in price and scarcity of fuel has contributed more directly than any other factor in increasing the cost and difficulty of operating the railways. Coal has risen in price from about $7 before the war to something like $50 in 1918; in 1916-17 the average price was about $25 or $30 a ton. In normal times the Central Argentine Ry. consumes annually about 400,000 tons; the Great Southern, 380,000; the Pacific, 280,000; the Western, 190,000; and other companies in proportion to their mileage and traffic. Not only has coal increased in price but the supply has been so limited that the railways have been forced to burn large quantities of wood.

It is estimated that the Great Southern, the Buenos Aires Pacific, the Buenos Aires Western, and the Central Argentine together use approximately 3,000,000 tons of wood annually under the present abnormal conditions. In addition, the industrial enterprises burn 8,000,000 tons, and all this fuel must be brought down from a restricted area in the northern part of the

republic. The carrying capacities of the lines serving this region are wholly inadequate, with the result that the Southern and some of the other systems having no wooded districts of their own to draw from have been unable to obtain sufficient wood at any price.

Coal Mining Development in Belgian Kongo

(British and South African Export Gazette)

Coal, and above all, good coking coal, is the one great essential to the adequate development of Katanga's vast mineral and other industrial resources. Had the great coal field, discovered some seven years ago in the region traversed by the Lukuga River, produced coal suitable for the manufacture of coke, it would doubtless have been exploited long ere this and despite the war, but we believe the small amount of development work originally attempted by the Societe Geologique et Miniere des Industriels Belges has long been at a standstill. Now, however, interest in the subject is revived in connection with the recent discovery—in which the concern mentioned participated—of important coal measures situated on the main railway line some distance north of Elisabethville. Whether these, unlike those in the region of Lake Tanganyika, will afford an early supply of coking coal remains to be seen. From the scanty evidence before us we are inclined to regard both fields as of very similar character, and, therefore, not likely to produce the class of coal required—at least, not until it becomes possible to carry the workings to a greater depth than has hitherto been reached.

In spite of this, there is good ground for anticipating a revival of practical work on the coal fields of Katanga, both in view of the great opening offering for bunker coal at Dar-es-Salaam, Zanzibar, and even Mombasa and Beira, and the advisability of converting the railway locomotives and lake steamboats of Katanga itself from the use of wood fuel to coal. With such large areas of coal measures already assured, it is unthinkable that a policy of inertia should be continued now that that incubus of war conditions is lifting, and especially in view of the possibility of striking coal suitable for the production of coke, for which the great local copper-smelting industry offers a market already large and capable of unlimited expansion. At present Katanga imports coal and coke from Rhodesia, mainly for the service of the copper-smelting industry to an annual value of, roughly, $262,500; but the country's actual requirements, in order to do away with the use of wood fuel and eventually to keep pace with the extension of the Cape to Cairo line northward, must far exceed this figure.

Abbreviations in Foreign Correspondence

American coal exporters, in corresponding with foreign firms, make frequent use of trade abbreviations and commercial terms which are not understood and cause considerable embarrassment. When an abbreviation is first used its meaning should be explained fully, as commercial terms, and particularly technical abbreviations, although familiar enough in business circles in the United States, may be entirely unknown abroad. Fluctuation in exchange and different systems of measurement cause sufficient perplexity to foreign merchants without this additional handicap of trade abbreviations or technical terms so often misunderstood or unintelligible.

Coal Mining in Coahuila, Mexico

The effects of the reëstablishment of the coal-mining industry in Coahuila, reports Vice Counsul Blocker from Piedras Negras, Mexico, under date of Feb. 20, have been very far-reaching, because other industries have been benefited. It is the opinion of well-informed persons that the development has reached a point where about 40,000 tons of coal (steam and railroad) and about 18,000 tons of coke are produced and marketed monthly, this being something like one-half and one-third, respectively, of normal production. The producers have now reached the point in their improvements and developments whereby the aggregate output could be rapidly and permanently increased to nearly normal, provided the market were in a condition to absorb the increase.

Owing to difficulties and peculiarities of the geographical and transportation conditions, it is economically impossible to market this coal south of Mexico City, on the west coast, in Sonora, Cananea, etc. To these districts fuels are imported, principally from the United States.

The recent great decline in the prices of metals, such as copper, lead and zinc, and the lack of a market for these ores, has affected the coal-mining industry. Several smelters have suspended operations entirely, and all have curtailed their work. This means a decrease in consumption of coal and coke.

Increase in Price of German Coal

Since Sept. 1, 1918, the price of coal and coke in Germany has doubled, reports the *Berliner Tageblatt* of Mar. 21, in printing the list of the basic rates effective Apr. 1, announced by the Rhenish Westphalian Coal Syndicate. Under the new schedule, the price of anthracite ranges from about $17 to $18 a metric ton (2200 lb.), coke brings from $20 to $22, and briquets from $15 to $16.50. This represents an advance since Jan. 1 of $5 a ton for coal and briquets, and $7.50 for coke. How much more than these prices is paid by the ultimate consumer is not noted.

The *Tageblatt*, while admitting that there is a certain justification for the rise because of the many strikes, which have kept down production and caused material increases in wages, laments bitterly over the decision of the coal barons, and declares that the high prices are dealing a heavy blow to German industry and constitute a real national calamity. It points out that the iron and steel men are likely again to increase the prices of their products as a result of the rise of the cost of fuel, and that the prospects for a resumption of German domestic and foreign trade are gloomy indeed. Before the war coal in Germany sold at from $4 to $5 a ton.

To Form Coal Export Association Under Webb Law

J. H. Wheelwright, of Baltimore, president of the National Coal Association, at a meeting of the Board of Directors of the association held at Cleveland, Ohio, on Apr. 23, told the directors that the Government had invited him to request the bituminous operators to form an export association, under the Webb law, somewhat similar to the organization of textile importers.

Mr. Wheelwright said Government officials had decided that assistance should be given to coal exporters in obtaining ships and in other ways, in order that conditions abroad might be alleviated by American coal and a permanent foreign trade in coal be established. Appointment of a committee to proceed with the formation of a coal exporters' association was authorized.

Coal for St. Lawrence Ports

The coal trade between Nova Scotia mines and St. Lawrence River ports, which was interrupted through an incident of the war, will likely be restored at an early date in consequence of a decision in the English courts in a suit brought by the Dominion Steel Corporation against a number of vessel owners. When war was declared the owners took the stand that their charters with the Corporation for carrying their coal were canceled, and sent the vessels on more lucrative business elsewhere for the past four years.

The value of this trade may be gathered from the enormous increase in imports of bituminous coal from the United States. During the year ending March 31, 1918, these imports of American bituminous coal to Montreal and Quebec amounted to $8,331,021, as compared with $2,418,169 for the year ending March 31, 1914. The difference, amounting to about $6,000,000 a year, will represent the amount of Nova Scotia coal trade to St. Lawrence ports which was lost through the action of these vessel owners. The courts have ruled that the vessels must be returned to the Dominion Steel Corporation until the expiration of their charters, which are on favorable terms for a long period of years, just as soon as they are released from Government service. The corporation will also claim heavy damages from the vessel owners for failure to carry out their contracts.

Coal in Maracaibo

Hard coal of good quality is found to the west of Maracaibo, in abundance on a concession owned by the Caribbean Coal Co., an American corporation. As yet no coal has been exported from this region, but it is expected that in a few years a railroad from the mines to deep water of the Gulf of Venezuela will be completed and that as much as 500,000 tons of coal can be exported from that mine annually.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Apr. 28 states that freight conditions are practically the same as a week ago, and that the few charters effected during this period were at the Chartering Committee's maximum rates. The demand for tonnage to carry coals to the River Plate has decreased considerably, and the report states that English firms are now selling Cardiff coal there at figures which American shippers cannot compete. Consequently American exporters are losing their share of the River Plate coal business.

The Chartering Committee's rates are as quoted below:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50; 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons dis. Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis., or $21 net, 600 tons dis.; Buenos Aires, $18.50 net, 600 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.50 net, 500 tons dis.; Bahia, $18.50 net. To Nitrate Range, $165.50 gross, prepaid.

COAL AND COKE NEWS

EDITED BY ALEX MOSS

Harrisburg, Penn.

Representatives of some of the largest producers of anthracite and bituminous coal in Pennsylvania on Apr. 22 entered protest against any increase in rates for workmen's compensation at the second conference on the suggested amendments held at the Capitol.

B. M. Clark, of Punxsutawney, representing the Central Bituminous Operators' Association, and James E. Eichenauer, of Pittsburgh, speaking for the Pittsburgh Coal Operators' Association, said that any legislation for an increase would be ill-advised at this time, as conditions are abnormal, costs are at the peak, the market is depressed, and the mines of the state are facing serious competition from other states. Mr. Clark made an extended argument, saying that sales are now made at a loss and that he does not see any immediate betterment.

John Brophy, representing the central Pennsylvania miners, of which he is the president, said that the mine workers did not expect the industry to be at a low ebb always, and that "the coal companies can afford this increase and should be made to afford it; the miners expect it and feel that it is due them." Mr. Brophy said that the market conditions were bad now, but looked for an improvement.

Thomas Kennedy, president of District No. 9 of the anthracite mine workers, said he could not reconcile the statements of the anthracite operators' representatives in agreement with those of the men from the bituminous field, because the conditions in the hard and soft coal fields are entirely different. In the anthracite region the mines are working six days a week with an advance in price coming. The miners, he said, were promised an increase in compensation and have been patient. He said that faith should be kept with them and reminded his hearers that in western states farmers organized politically. In Pennsylvania, he said, the miners are organized.

Brownsville, Penn.

In the central Pennsylvania bituminous field the mines producing the United States Navy preferred grades of smokeless coal are faring well and working better than in the recent past. In the western Pennsylvania field there is little change. In the Connellsville coke region the reduction in output keeps steadily on, but there is a feeling among many that the bottom must soon be reached notwithstanding the controversy over steel prices.

The proxy committee of the United Coal Corporation has notified stockholders that since sending out the proxies for the annual meeting a proposition has been received from the J. H. Hillman & Sons Co., and approved by the board of directors of the United Coal Corporation, for the mutual operation of these and other properties, and that the name of the latter company be changed to "Hillman Coal and Coke Co." The proposition will be submitted for the approval of stockholders of the United Coal Corporation at the annual meeting to be held May 5.

There would not seem to be much doubt as to how this proposition will be received, as Mr. Hillman is the majority stockholder of the United Coal Corporation. The "other properties" will presumably include the Hecla Coal and Coke Co., of which Mr. Hillman is principal owner and president, and possibly the Thompson-Connellsville Coke Co., of which Mr. Hillman will soon obtain control.

Charleston, W. Va.

High rates to lake points from West Virginia's producing regions were impeding the fullest development of lake business during the third week of April, in addition, of course, to the fact that there was much coal still on hand in lake territory. Despite such conditions a slightly larger volume of coal was being moved from West Virginia to lake points than had been the case earlier in the month, but such increases were limited to one or two districts, tending, of course, to increase production in such districts.

Coal is moving to tidewater in about the same proportion as it had been in preceding weeks. Export orders are becoming somewhat more plentiful, some coal having been purchased for delivery to points in Sweden. The fullest development of export business has been greatly retarded insofar as West Virginia coal is concerned by a shortage of vessels. Such export orders as have been received, however, have given impetus to production at some mines in the state.

Strict adherence to the imposition of penalties for demurrage is tending to make tidewater embargoes no longer necessary. Shipments of coal for railroad use during the week ending April 19 see-sawed considerably. During part of the week railroad fuel constituted one-third of the total shipments from certain regions. By the middle of the week such shipments had materially decreased. Railroads are not purchasing West Virginia fuel on long-time contracts.

The large amount of coal it has been necessary to screen in getting out prepared sizes has had its effect on the price of slack, which being accumulated in large quantities, has declined to some extent.

Production at the most was not over 45 per cent. during the third week of April in West Virginia.

There are in the southern part of West Virginia a total of 767 mines, or rather mining properties. This is shown in geographical mining maps prepared by Secretary Walter H. Cunningham, of the West Virginia Coal Association, who resides at Huntington. Such properties are located on the Virginian, Chesapeake & Ohio, Norfolk & Western, Kanawha & Michigan, Coal & Coke and Kanawha & West Virginia railroads.

After May and June no further examinations to determine the fitness of miners to hold mine foremen's certificates will be given, but during May and June seven examinations will be held under the auspices of the State Department of Mines on the following dates and at the following places: Fairmont, May 13; Wheeling, May 20; Charleston, May 27; Mt. Hope, June 3; Thomas, June 10; Logan, June 17; Welch, June 24. Another examination will be held for the benefit of those taking the miner's short course, at the end of that course at the State University.

Huntington, W. Va.

In connection with the announcement recently made as to the plans of the Main Island Creek Coal Company at Sterrett, it is also stated that within a short time the company will be able to begin the operation of six new mines at that point, working in the Island Creek seam. Through the operation of those new mines the company will be able to increase its total product to the extent of 6000 tons a day at least. This will place the Main Island Co. among the large producers of the state, as the company has already an annual production of 846,696 tons. Opening of the new mines will relieve the unemployment situation in the Logan field, as many miners will be given work. In planning for the extension of operations the company is also giving much consideration to the advancement of living conditions among employees and is providing adequate recreational facilities.

Coal from the mines of the Island Creek Coal Co. operating in the Logan field, filling 23 barges, left Huntington on Saturday, Apr. 19 in one coal tow, the largest ever shipped by water from Huntington in one tow. Had the coal been loaded in average capacity railway cars it would have required 322 cars to transport the coal.

Fairmont, W. Va.

A number of mines in the northern part of the state, and particularly in the Fairmont region, are working on export orders, some of the coal so mined being for consumption in Sweden and some for consumption in Italy. Undoubtedly such a class of business has tended to prevent greater idleness among the mines in northern West Virginia. There would have been, and there would be now, a large volume of such business if only the vessel space could be secured for the transportation of such coal.

There was, to some extent, a diminution of lake shipments from the Fairmont region during the week ending Apr. 19. Coal was being moved to lake points at the rate of about 50 or 60 cars a day. Coal for tidewater was moved at the rate of about 40 or 50 cars a day; that is, from the Monongah division of the Baltimore & Ohio. While the shipment of railroad fuel started off with a flourish, it gradually diminished during the week, being at the rate of about 135 cars a day during the latter half of the week.

It is regarded as certain that over half the mines in the northern part of the state were idle during the week and that production on the whole was not over 45 per cent., if that much. Contrasted with previous weeks, the demand for coal is livelier.

Louisville, Ky.

The Northeastern Kentucky Coal Operators' Association, in session at Paintsville, Ky., recently decided to undertake welfare work on a much larger scale, in an effort to provide better roads, schools, churches, and homes for their employees, of whom there are about 20,000 in all. A committee was named which will investigate conditions in the best fields, and endeavor to go them one better in an effort to make the miners more satisfied.

A legislative committee was named to advise the members of all pending legislative enactments, either Federal or state, and to coöperate fully with the National Coal Association, American Mining Congress and Kentucky Mine Owners' Association in preventing antagonistic legislation, and for the purpose of having enforced good state and Federal laws relative to mineral rights, liquor, compensation matters, etc.

The Community Welfare and Publicity Committee will endeavor to bring about better relations between miners and mine owners, promote common interest between producers, employees, consumers and carriers, to the end that mines may be operated on a fuller and better schedule.

Victoria, B. C.

An action is in progress in the courts of British Columbia in which the Canadian Colliers (D), Ltd., are the plaintiffs and the Pacific Coast Coal Mines, Ltd., the defendants, the suit being for damages for trespass and for an accounting and payment for coal alleged to have been taken from the Alexandre mine property, South Wellington, in 1911. The plaintiffs maintain that the coal was taken without their knowledge or consent, and it is understood to be the plea of the defendants that whatever was done by them was with the consent of the plaintiff company's officials.

With further reference to the Settlers' Rights Act of British Columbia, which was disallowed by the Dominion government in 1917 and on being re-enacted by the Province last year was refused the signature of the Lieutenant-Governor, it is interesting to note that the Vancouver Island settlers interested are making a concerted move to bring their case directly to the attention of the Federal Government. Meetings of those who have property without the coal rights therein have been held, and it is probable that a delegation will leave the Pacific coast shortly to carry the grievances to the ears of those in control at the Canadian capital.

The Merritt Collieries, Ltd., is opening up a new No. 3 slope. It is the Diamond Vale field and when completed is expected to result in a material increase in the coal production of that section.

A distinct improvement is apparent in the coal production of British Columbia during the month of March in comparison with that of February, there being a difference of approximately 28,000 tons. The total for March is about 223,000 tons. The reason definite figures are not given is that

returns have not been received from one or more of the smaller of the Province's producing mines. In March the Crow's Nest Pass Collieries were working at least five days a week, which is better than was done in February. It may be observed incidentally, in connection with the Vancouver Island output, that the new Wakesiah mine of the Canadian Western Fuel Co., which was expected to be in operation by this date, is still in the development stage, the work of opening up the property having ceased some weeks ago.

New York, N. Y.

Charles S. Allen, secretary of The Wholesale Coal Trade Association of New York, representing that organization and a number of individual producers and shippers, has filed with the Interstate Commerce Commission the complaint authorized by the Association, against Walker D. Hines, Director-General of Railroads, and 23 railroad companies as defendants with a view of having the Commission establish new demurrage regulations and also to issue an order to prevent the collection of any unlawful demurrage charges which have been assessed against the complainants since Dec. 1, 1918, and which remain unpaid at the present time.

These charges, Mr. Allen estimates already amount to $500,000 on bituminous shipments in the New York harbor alone, and to $1,000,000 on shipments of anthracite and bituminous in the ports of New York, Baltimore and Philadelphia.

Mr. Allen in his complaint charges discrimination against the tidewater ports in that Mr. Hines or his agents, the railroads, maintain at the so-called lake ports a demurrage rate or charge of $1 per car per day in excess of five days, or other number of days, or free time averaged over periods of six months, or any other periods exceeding one month, while contemporaneously maintaining at the so-called tidewater ports of New York, Philadelphia, Hampton Roads and Baltimore a demurrage rate of $2 per car per day in excess of five days' free time average over a period of one calendar month, which he says "results in an undue and unreasonable preference and advantage to said 'lake ports' and an undue and unreasonable prejudice and disadvantage to the said 'tidewater ports' and to the other consuming centers to which coal is shipped through such ports; and also results in undue and unreasonable preference and advantage to buyers in the coal fields shipping to or through the lake ports as against buyers shipping to or through the tidewater ports; that if due consideration be given all the facts, circumstances and conditions surrounding the transportation, delivery and handling of coal to the tidewater ports as compared with the lake ports, a longer free time, averaged over a longer period and with no higher demurrage charge or penalty would be justified at the tidewater ports than at the lake ports."

On and after today (May 1) the office of J. W. Howe, Commissioner of the Tidewater Coal Exchange, will be located in this city instead of in Washington, D. C. At the same time it was announced that J. W. Searles, the Deputy Commissioner at New York, had resigned and would return to his former position as sales manager of the Pennsylvania Coal and Coke Corporation in the Whitehall Building, and that A. D. Thompson, who was assistant to Mr. Searles, had also resigned and had accepted a position with the Wittenberg Coal Co., 11 Broadway. R. A. Magruder, who was chief clerk in the Washington office of the Exchange, will continue to occupy the same position in the New York office.

Bids were opened in the New York War Department offices on Apr. 22 for furnishing and delivering 5500 tons of bituminous coal, deliveries to be made between May 1 and June 30 to places designated by the Quartermaster's Corp. Bids were based on net tons f.o.b. mines, and were as follows: Alden Coal Mining Co., Pool 10, $2.38; Pool 11, $2.24. Whitney Coal Mining Co., Philadelphia, Pool 11, $2.10. Cortright Coal Co., Philadelphia, Pool 4, $2.75; Pool 9, $3.10; Pool 10, $2.95; Pool 11, $2.60. E. P. Bavlo, Hampton, N. J., Pool 10, $2.09½. Dickerman & Englis, Pool 10, $2.65. Salem Coal & Coke Co., Clearfield, Penn., Pool 14, $2.49. Curry Coal Mining Co., Expedit, Penn., Pool 10, $2.60. Huskin Coal Mining Co., Windber, Penn., Pool 10, $2.75. Midland Mining Co., Cumberland, Md., Pool 10, $2.65. Seaboard Coal Co., New York, Pool 11, $2.60. Indiana Smokeless Coal Co., Pool 11, $2.09. Barnes & Tucker, Philadelphia, Pool 10, $2.55. Operators' Coal Mining Co., Johnstown, Penn., Pool 10, $2.65; Pool 11, $2.65. Campbell, Peacock & Kinzer, Philadelphia, Pool 10, $2.13.

PENNSYLVANIA

Anthracite

Middleport—The Kaska colliery of the Alliance Coal Co., near here, will be placed in operation soon. The dewatering of the workings is a big job and is causing the delay in resuming mining at this time.

Harrisburg—President John Brophy, of the central Pennsylvania or No. 2 district of the United Mine Workers of America, with a large delegation of union men on Apr. 9, made a strong protest against the terms of the anti-sedition bill.

Wilkes-Barre—As soon as an adjustment is made of the assessment valuations on its property in Dauphin County, the M. A. Hanna interests intend to electrify their collieries. It is declared that the proposed change will cost between $1,250,000 and $1,500,000. Steam is now being used for power.

Berwick—Coal dredging in the Susquehanna River between Berwick and Bloomsburg has already begun with excellent prospects of securing large quantities of coal at a profitable producing cost. Several ambitious Columbia County coal dredgers make more than a comfortable living in this business.

Hazleton—Engineers employed by Weston Dodson & Co. at their Locust Mountain colliery are now engaged in making a survey of the G. B. Markle Co. operations, with a view to applying more efficient mining plans. The presence of these men on the Markle property gave rise to a rumor that the Dodson company would acquire the Markle holdings, which rumor was promptly denied by the latter company.

McAdoo—A corps of engineers has been busy between this point and Rush Valley during the past few weeks, but its mission is a mystery. The work of proving for anthracite is under way on the Kinkie tract, at Quakake, and it is thought that the survey is in connection with this activity. Miners who were employed at Silver Brook years ago declare that there is plenty of coal in the basin which lies between Hazleton and Tamaqua.

Carbondale—The Lackawanna County Coal Co. has opened an office in this city. The new concern owns in fee the West Mountain Coal Co.'s property at Jermyn and will operate on a fee-simple lease the property of the Falls Mining Co. and on lease terms the Northeast colliery at Simpson. About two million tons of coal are said to be available for mining at the three holdings just enumerated. In the near future all the coal from the three workings will be prepared for market at the Northeast breaker. The breakers at the Falls and Jermyn plants will be dismantled. It is planned to spend about $50,000 in modernizing the Northeast colliery, and operations at the collieries will be enlarged. Electric equipment is being installed at all the plants. Coal-cutting machines are also to be provided.

Bituminous

Indiana—Pleasant Valley, a village a short distance from Lovejoy is to be the location of a new coal plant to be built by the Clearfield Bituminous Corporation. Lumber is already on the ground.

Altoona—Thirty miners presented themselves for examination here, Apr. 8, when the examining board for the tenth bituminous district met to inquire into their fitness for the offices of mine foreman and fireboss.

Portage—Alexander Brown, of Portage, a mine foreman, died at the Memorial Hospital, Johnstown, of injuries sustained on Apr. 12 in the Brown and Ghroke coal mines at Portage when he was caught under a fall of rock, the rock crushing his chest.

Webster—The United Coal Corporation is changing its Ella mine, near here, from making its own power, to power purchased from the West Penn Power Co. The rope haulage and fan, which are now steam-driven, are also being changed to electric drive.

Savan—The new mines of the Dor-Mar Coal Co. here have been closed for a period of two weeks on account of the installation of new machinery. Boilers and a haulage engine have been added to the equipment and the mines resumed work a week ago Monday.

Brownsville—The Snowdon Coke Co., operating near this place, has purchased seven acres of surface about halfway between its operation and Brownsville, on the Pittsburgh-Brownsville paved road, and will build thereon a number of houses for their employees during the spring and coming summer.

It is reported that an agreement has been reached between J. Harte Hillman, Jr., of Pittsburgh, Penn., president of the Hecla Coal and Coke Co. and William H. Brennan, of Uniontown, Penn., president of the Thompson-Connellsville Coke Co., whereby Mr. Hillman will take over the control and management of the Thompson-Connellsville Coke Co. May 1 instead of waiting till July 1, as previously arranged.

Waterman—The store of the Traders' Supply Co. at the Coy mines near here was destroyed by fire recently. Upon investigation it has developed that it is the work of some dissatisfied workmen in this vicinity. The loss is placed at several thousand dollars as the building and stock was a total loss.

Johnstown—Almost one hundred applicants appeared before the examining boards of the sixth, twenty-fourth and thirtieth districts at the examination held here last week. All the boards held the examination in the same room. The thirtieth district board had the largest number, with 44 applicants for mine foreman.

Indiana—One of the landmarks of Indiana, Library Hall, is being torn down. Library Hall stood on the large plot of ground on Church St., which was purchased by the Rochester & Pittsburgh Coal and Iron Company as a site for their new office building here. Work will probably be started on the new building at once.

Homer City—The tipple of the Homer City Coal Co. at the Tearing Run mine was partially destroyed recently by a charge of dynamite being exploded under one of the tipple piers. There has been considerable trouble with some of the miners in this vicinity lately, and this is thought to have been a plot by the miners to get even for the coal companies in closing down some of the mines here. The company has offered a reward of $500 for the arrest of the dynamiters.

DuBois—The fourth bituminous district had only 29 applicants for certificates when the inquisitorial board met under the leadership of J. I. Thomas, the inspector of the district.

Consolidated Coal Co. officials inspected nearly all the mines of that company in West Virginia on Friday, Apr. 11, the party including Carl R. Gray of Baltimore, president of the Western Maryland Ry. and a director of the coal company; Geo. T. Watson, assistant to the president; Frank Lyon of Fairmont, general manager of operations; A. Brooks Fleming, Jr., Assistant general manager of operations; C. H. Tarleton, manager of the West Virginia division; A. T. Watson, purchasing agent; F. K. Day, district superintendent; L. A. Riggs, division engineer; F. R. Raeder, district engineer; H. R. Pratt, of Baltimore, chief engineer of the Western Maryland Ry.

Pittsburgh—The Pittsburgh Coal Co. has nearly completed a three-mile connection to its Montour-Clairton branch in the southern part of Allegheny County and the northern part of Washington County in order to develop over 4000 acres of the finest coal in these two counties. The officials regard the construction of this new branch and the development of the new mine, which will be known as "Montour No. 10," as the most important work undertaken by the organization in several years, both in size and immediate results. The output will run about 5000 tons a day. Most of the miners who will work the mine will come from the Lick Run mines of the company on the Baltimore & Ohio Railroad, a few miles below the new development.

WEST VIRGINIA

Elkins—The Elkins Coal and Coke Co. has recently completed the entire electrification of its local plant. Power for operation is furnished by the West Virginia Traction and Electric Company.

Logan—Impetus has been given to the production of coal at the Logan mines of the Hutchinson Coal Co. by the receipt of orders for coal for lake delivery, such orders insuring operations on a full-time basis for the present.

Fairmont—So as to provide for additional railroad facilities the Connellsville & Dawson Coal Co. is planning for the construction of a double side track from its mines to the Baltimore & Ohio R.R. at Westchester, W. Va.

Fayette—The new power plant of the Ajax Coal Co. will be ready for operation June 1. The buildings are of stone and the equipment consists of two 150-hp. boilers, one 136-hp. engine, 96 kw. The work is being looked after by J. H. Belcher, of Cedar Grove, W. Va.

Wheeling—The Wheeling & Lake Erie Coal Co., a subsidiary of the M. A. Hanna Co., has completed negotiations for the acquirement of the three mines of the Pittsburg-Belmont Coal Co., located in Belmont

County, Ohio. It is understood that the consideration was about $1,500,000.

Thomas—For the time being, work has been suspended at the Elk Garden, West Virginia Junction and Davis plants of the Davis Coal and Coke Co. This suspension is of course only of a temporary nature. The company is operating its mines elsewhere on a basis of four days a week.

Alton—The Huston-Ziler Coal Co., which recently filed articles of incorporation with a capital of $100,000, is understood to be arranging plans for the commencement of work at an early date for the development of a tract of about 200 acres of coal properties acquired. It is expected to have an initial daily capacity of about 1½ cars.

Macdonald—The question of building new tipples at its plant at Whipple, Summerlee and Lochgelly, W. Va., is under consideration by the New River Co., operating in the New River field, the company having in mind an increase in the capacity of its mines, which now produce coal at the rate of 12,000 tons a day when in full operation.

Benwood—Announcement has been made that operations have been suspended indefinitely at the local plant of the Semet-Solvay Co., manufacturer of coke, effective Apr. 12, to allow for extensive improvements, etc. It is understood that the coal-mining industry in local sections will be effected by the suspension, as they furnish thousands of tons of coal to this plant monthly. This is the first time that the company has suspended operations in the past three years.

Fairmont—The Federal Government paid over to the owners of the land on which the plant of the Domestic Coke Corporation is being built the sum of $64,000. This was in payment for about 60 acres of land. The price paid per acre varied from $1000 to $1700. The number of men now engaged in construction work on the by-product plant is now in the neighborhood of 300. Work is also being pushed on a connecting track with the line of the Baltimore & Ohio Railroad.

Wheeling—With $1,500,000 said to have been the price paid, the Pittsburgh Belmont Coal Co., operating in the Eastern Ohio field, has come under the control of the Pittsburgh & Lake Erie Coal Co., one of the properties of M. A. Hanna & Co. This deal exceeds in magnitude any of recent months in eastern Ohio territory and involves a change in the ownership of three mines—No. 1 and No. 2 at Neff's and the No. 3 at Lafferty—making eight mines in all which will be operated by the Pittsburgh & Lake Erie Co. Acquisition of three additional mines will give the Hanna interests a greatly increased production in eastern Ohio. It is said, in fact, to be their intention to make their operations the largest in that field. Alexander Neff, president of the Pittsburgh Belmont Co., and Franklin Neff, vice president of that company, will probably remain with the new owners of their mines.

ALABAMA

Birmingham—Incomplete reports in the hands of Chief Mine Inspector C. H. Nesbitt, indicate a total coal production of approximately 18,000,000 net tons in Alabama during 1918. The output for 1917, the largest on record, was 20,413,811 tons. It is estimated that the coke production will fall short around 500,000 net tons, the make for 1917 being 4,868,598 tons.

OHIO

Zanesville—Realty deeds filed recently for record show the sale of the Harold Robertson farm, 385 acres in Washington Township, to Edward A. Laugenbach, of Canton.

ILLINOIS

Nokomis—The Nokomis mine, the Kortkamp mine, the Taylor Springs mine and the two Witt mines, which have been in the hands of T. C. Keller, receiver, were recently sold and bought in by the bondholders and will hereafter be operated as the Illinois Coal Properties Co., with Keller as superintendent.

Springfield—The Capitol Mine of the Springfield District Coal Mining Co. has been closed down and will remain closed several weeks while repairs are being made. The Nadrews and Woodside mines are also closed temporarily.

A bill has been introduced in the house providing for the inspection of coal mines every six months by inspectors employed by the Department of Mines and Mining. It has been referred to the Committee on Industrial Affairs.

Auburn—Two miners, Harry H. Sanders and Edward Smith, were recently killed by an explosion in Panther Creek mine, four miles north of here, attributed to a windy shot. Two mules also were killed. The two men were the only miners in the part of the mine where the explosion occurred. The accident occurred at 5 o'clock, just after the night shift had ceased work. The mine is a new one, about 300 ft. deep, owned by Solomon Brothers, of Auburn, and employs about 140 men.

Hillsboro—Drill tests of the quantity and quality of the coal field between Bunker Hill and Shipman are so satisfactory that A. W. Crawford, of this place, who represents a syndicate, announces that the coal rights of 15,000 acres will be paid for as soon as the titles can be secured. What interest is behind the proposed new development has not been made known, but J. D. Hurd, of Los Angeles, Cal., has been conferring with Crawford. The latter states that the field will not be developed, probably, for two years.

INDIANA

Terre Haute—Strikes affecting 840 miners in three mines are reported in the Terre Haute region. About 300 men are out at the Hall-Zimmerman Black Bettie mine. The trouble is said to be due to division of daywork. About 300 more men are out at Fayette mine, where the same kind of trouble exists. The Vandalia mine No. 28 has also closed for the same cause.

Du Quoin—Drilling has recently been completed on a tract of land 1½ miles south of town, owned by H. C. Miller, of the First National Bank of this city. The results of the test have not yet been made public and it is not known how soon steps to develop will begin.

It is reported that the Federal mine near Carterville, southeast of here, formerly known as the Burr mine and owned by the Peabody Coal Co., Chicago, is to begin hoisting coal again next week after being shut down since last November. According to Superintendent C. L. Rudder, the mine is to operate steadily from now on for an indefinite period. It is understood that the company has secured a large contract which will keep the mine working five days a week.

De Soto—The De Soto Coal and Mining Co., of which Frank Dickie is superintendent, is sinking its shaft down into a second vein of coal which was found to be of good quality coal from 3 to 4 ft. thick and good roof over it.

The E. J. Scott Coal Co., operating a strip mine at the southern edge of the city limits, is steadily increasing its daily output. The stripping is being done with a Bucyrus shovel which is said to be one of the largest in use. At the present time coal is being produced every day and one day's output fills from 30 to 35 railroad cars. The vein, which lies from 40 to 50 ft. underground, is an excellent grade of coal and is clean, as it is mined without special preparation. After the large Bucyrus shovel has uncovered the coal it is then loosened with dynamite and loaded into railroad cars by a smaller-sized caterpillar-type shovel.

Personals

James O'Donnell, a former mine inspector, is now superintendent of the new Raven Run Coal Co. at Raven Run, Penn.

Edgar E. Pike, who in civil life is president of the Marion County Coal Co. at Centralia, Illinois, is now in the U. S. Army service in the recently opened Army Hospital at St. Louis.

G. A. Murphy has severed his connections with the Independence Coal and Coke Co., Salt Lake City, Utah, to accept the superintendency of the Spring Canyon Coal Co. operations at Storrs, Utah.

W. H. Williams has resigned the vice presidency of the Hudson Coal Co., Scranton, Penn., to become president of the Wabash R.R., with offices in New York. **Charles Dorrance, Jr.**, general manager, has been named to succeed Mr. Williams.

Edward M. Fuller, construction engineer of the Utah Fuel Co., Salt Lake City, Utah, has tendered his resignation, to take effect May 1. Mr. Fuller will enter into a partnership with J. J. Coan, their business being engineering and contracting, under the firm name of Coan & Fuller, with offices at Salt Lake City, Utah.

Harold E. Bissell, a well known coal man, holding, for a number of years past, the positions of secretary-treasurer of the Black Diamond Coal Co., and secretary of the Benoit Coal Co., affiliated interests at Birmingham, Ala., has severed his connection with the above companies and purchased the business of the W. W. Phelps Motors Co., distributors for the Reo and Marmon cars in the Birmingham district.

G. C. Weitzell, who was president of the New Pittsburgh Coal Co., of Columbus, Ohio, when it was absorbed by the Pittsburgh Coal Co., has been made vice president of the late company in charge of Ohio and Kentucky mining properties and operations. **J. B. L. Horsberger** has been made vice president and comptroller in charge of taxes and insurance, with headquarters in Pittsburgh.

Capt. Le Roy Aikman, a member of the Alaska Fuel Commission, has been ordered to report for duty in Alaska and has departed for the Pacific Coast after a few days' visit with relatives in southern Illinois. Capt. Aikman was stationed in Alaska in 1912 at the time the Navy was making investigations of the fuel situation in that territory, and the return trip is to complete this work. The first experiment made by the Government showed that the Alaska coal was not equal to the West Virginia Pacahontas coal, while the second test from another field showed but a fraction of one per cent. difference in heat units between the two coals.

Coming Meetings

American Wholesale Coal Association will meet on June 3 at Cleveland, Ohio. Secretary, L. Romanski, Chicago, Ill.

Illinois Mining Institute will hold its annual meeting May 22, 23 and 24. Secretary, Martin Bolt, Springfield, Ill.

National Coal Association will meet May 21, 22 and 23, at Congress Hotel, Chicago, Ill. Secretary, J. D. A. Morrow, Washington, D. C.

Illinois and Wisconsin Retail Coal Dealers' Association will meet at Hotel Nelson, Rockford, Ill., June 4 and 5. Secretary, I. L. Runyan, Chicago, Ill.

International Railway Fuel Association will hold its annual meeting May 19-22 at the Hotel Sherman, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

Retail Coal Dealers' Association of Texas will hold its annual meeting on May 19 and 20 at Fort Worth, Tex. Secretary, C. R. Goldman, Dallas, Tex.

Central Pennsylvania Producers' Association will hold its annual meeting May 15 at Chamber of Commerce Building, Altoona, Penn. Secretary, Charles O'Neill, Altoona, Penn.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 10 in the Keith and Perry Building, Kansas City, Mo. Secretary, C. N. Fish, Leavenworth, Kans.

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind., subject to ratification of executive committee. Secretary, J. W. Paul, Pittsburgh, Penn.

National Retail Coal Merchants' Association will hold its annual convention at Buffalo, N. Y., May 14-16, with headquarters at Lafayette Hotel. Secretary-Manager, E. B. Gordon, 1727 Pennsylvania Ave., Washington, D. C.

Kentucky Mining Institute after having skipped two years, one on account of the war and the other due to the influenza epidemic, expects to hold its annual meeting this year. While the date and place of meeting have not definitely been set, it will probably be held on May 30 and 31 at Lexington, Ky. Secretary, C. W. Strickland, Huntington, W. Va.

Trade Catalogs

Stowage of Ship Cargoes. Compiled by the Division of Tabulation and Statistics. War Trade Board, Bureau of Research and Statistics. Unillustrated; pp. 69; 5¾ x 9½ inches.

Vulcan Soot Cleaners for Return Tubular Boilers. Vulcan Soot Cleaner Co., Dubois, Penn. Bulletin. Pp. 4; 8½ x 11 in.; illustrated. Describes the Model M front-end type and the Model R rear-end type. Illustrations show the cleaner installed in typical settings.

Use of Shoveling Machines in Underground Mining. Myers-Whaley Co., Inc., Knoxville, Tenn. Catalog. Pp. 20; 10½ x 8¼ in.; illustrated. An interesting compilation of data concerning the general

construction of shoveling machine. Many applications of the machine in actual practice are given.

The Strong Arm of Industry. Electric Hoist Manufacturers' Association, New York, N. Y. Booklet. Pp., 12; 8½ x 11 in.; illustrated. Issued for the purpose of affording the reader some conception of the large field of usefulness for overhead electric hoists. Twenty-two different hoist applications are pictured.

Steamobile Road Truck. Winslow Boiler and Engineering Co., Chicago, Ill. Catalog. Pp., 16; 8x 10½ in.; illustrated. Introduces the application of the steam power plant in the automobile field. The boiler and engine comprising the power plant are described and pictured, and the specifications given for a five-ton steamobile truck.

Industrial News

Tiffin, Ohio—The Schaffer Engineering and Equipment Co. announces that it has changed the location of its offices from Tiffin, Ohio, to the Peoples Bank Building, Pittsburgh, Penn.

Pittsburgh, Penn.—The Concordia Safety Lamp Co. announces its removal from 420 Fulton Building to 317 Highland Building, Penn and Highland Aves., East End, Pittsburgh, Penn.

Charleston, W. Va.—No time will be lost by the Tolbert Smokeless Coal Co. in rebuilding the tipple and store building of the company. These structures were burned down in a fire a few weeks ago.

Morgantown, W. Va.—The West Virginia Traction and Electric Co. has recently completed the installation of a quantity of new coal-handling apparatus in the Morgantown power plant, to facilitate operations.

St. Louis, Mo.—The two-story frame coal chute of the Terminal Railway Association of St. Louis at Brooklyn, Ill., was destroyed by fire recently, with a loss on building, equipment and contents of about $100,000. The cause is not known.

Newcomer, Penn.—The Continental No. 3 mine of the H. C. Frick Coke Co., at this place intends erecting a belt conveyor from the bottom of the slope to the mine entrance, the coal being dumped into a railroad tipple without further transportation.

Wenonah, N. J.—A community coal yard is maintained by this village. When coal arrives citizens who have filed orders are notified to send check or cash to cover cost plus a slight margin for operating expenses. The borough teams then deliver the coal.

Charleston, W. Va.—With a capital of $25,000 the Curtis Branch Coal Co. has been formed, this company intending to establish operations at Ashford on Coal River, E. E. Huddleston of this city and others being the prime movers in the organization of the new company.

Columbus, Ohio—The Columbus Board of Education will soon advertise for bids for approximately 6000 tons of coal for the various school buildings of the city. Several dealers are urging the board to buy early in order that better service in the way of delivery can be rendered.

St. Clairsville, Ohio—The Pittsburg Belmont Coal Co., which has been operating three mines in Belmont County, has sold its holdings to the Wheeling & Lake Erie Coal Co. at a price about $1,500,000. The first-named company was controlled by Columbus and St. Clairsville men.

New York, N. Y.—There was carried by the Lehigh Valley R.R. Co. during the year ended Dec. 31, 1918, 15,522,953 tons of anthracite and 4,826,049 tons of bituminous coal and coke, according to the annual report of the company. In 1917 the road carried 14,916,894 tons of anthracite and 3,784,672 tons of bituminous coal and coke.

Boston, Mass.—The Bailey Meter Co. will move its main office and works from Boston to Cleveland, Ohio, effective May 1. The Boston office, with H. D. Fisher as manager, is retained to handle sales and engineering service work in the New England district. For the present, New York and Philadelphia districts will be covered from Boston and all other districts will be covered from Cleveland.

New York, N. Y.—The newly organized S K F Industries, Inc., held a sales convention at Hotel Traymore, Atlantic City, Apr. 29, 30 and May 1. The sales policies and methods of the new company, which is a consolidation of S K F Ball Bearing Co., the Hess-Bright Manufacturing Co., Atlas Ball Co. and Hubbard Machine Co., were discussed. About 45 salesmen and executives were present.

Allentown, Penn.—The Traylor Engineering and Manufacturing Co., by means of an attractive four-page folder, extends to those interested an invitation to visit its shops during the week of Apr. 28 and view the 60-in. Traylor "Bulldog" gyratory crusher built for the Michigan Limestone and Chemical Co. This is said to be the largest stone crusher in the world, having two receiving openings, each 60 x 190 in., and a capacity of 2500 tons of crushed stone per hour.

Columbus, Ohio—The Sunday Creek Coal Co., recently formed by a consolidation of the properties of the Sunday Creek Coal Co., of New Jersey, the Buckeye Coal and Railway Co. and the Ohio Land and Railway Co., has opened branch offices in Grand Rapids, Chicago, Toledo, Findlay and Ft. Wayne. The Toledo office will be under the charge of M. D. Kinsey, the Grand Rapids office under the charge of R. D. Teele, and the Findlay office in charge of F. J. Kelly. Other managers will be named later.

Cleveland, Ohio—Bituminous operators producing three-fourths of the country's soft coal rejected a proposal made by Fuel Administrator Garfield to the end that the Government continue to direct the affairs of the industry after the proclamation of peace. The plan, which had been submitted to operators and miners for ratification or rejection, came before the directors of the National Coal Association at a meeting held Apr. 23 on a referendum vote from approximately 2500 operators. Directors had been instructed by the various producing fields as to how they should vote.

Marion, Ill.—The White Ash mine at Marion, southeast of Duquoin, has been closed down in order to render it possible to make extensive repairs. A new dynamo is being installed, the tipple rebuilt and automatic loaders provided. No. 8 mine, at Clifford, owned by the Big Muddy Coal and Iron Co., started operating again Tuesday, Apr. 15, after being closed down since last November. During the intervening time extensive improvements have been made, a new wash house has been built and much money expended in repairing and replacing equipment.

New York, N. Y.—Of interest to all users of bearings is the recently announced reorganization, effective May 1, whereby the products of the Hess-Bright Manufacturing Co., the S K F Ball Bearing Co., the Atlas Ball Co. and the Hubbard Machine Co. will be sold through one central organization. The new company will be under the direction of B. G. Prytz, president; W. L. Batt, vice president; J. P. Walsh, comptroller, and S. B. Taylor, sales manager. The principal office will be at 165 Broadway, New York City, with branches at Boston, Philadelphia, Atlanta, Buffalo, Cleveland, Detroit, Cincinnati, Chicago and San Francisco.

Charleston, W. Va.—There were only 18 fatalities in and around West Virginia mines during March, the lowest number recorded in some time. It seems to be impossible to guard falling roof slate, etc., that still being the largest single cause of fatal accidents in the mines, as, for instance, the total number of fatal accidents from that cause in March was 18—66⅔ per cent. of the entire number. Two deaths followed mine car accidents within the mines and a mine machine accident was responsible for another death. Mine car accidents on the outside of the mines cost the lives of two men. There were six fatal accidents in McDowell County and five in Fayette. Of the total number of mine fatalities in March, 11 were among Americans, the remaining seven being foreigners.

Columbus, Ohio—Ohio produced 47,849,-236 tons of coal in 1918, states George F. Miles, chief statistician of the Ohio Industrial Commission, in a bulletin issued Apr. 19. This showing exceeds by 6,000,000 tons that of any previous year, and was made under the impulse of speeding-up measures incident to war needs. Belmont County, in the eastern Ohio field, is credited with 12,165,253 tons, or about one-fourth the total for the entire state. Jefferson County ranks next, with 7,226,314 tons, and Athens County, in the Hocking district, is third with 6,654,682 tons. the other seven of the ten leading coal-producing counties had the following production: Guernsey, 4,493,718 tons; Perry, 3,542,338; Hocking, 2,347,657; Tuscarawas, 2,102,419; Harrison, 1,817,730; Meigs, 1,372,468; Noble, 994,889. The state's output was contributed to by 31 counties. Five-sixths of the mining was done by machinery.

Huntington, W. Va.—The Ohio Valley Mine Car and Manufacturing Co. has been organized principally through the efforts of Huntington business men with an authorized capital of $400,000. The company will manufacture mine cars and other mine equipment for sale to mines in West Virginia and Kentucky, but its plant—yet to be built—will be at Ironton, Ohio, the site for buildings having been provided by the Chamber of Commerce of that community. Pending completion of the new plant, the buildings of the Ohio Valley Machine Works, which have been purchased by the new company, will be utilized, this company having been engaged in the manufacture of mine cars. The new company was organized mainly through the efforts of M. E. Brown, of the Nuller Supply Co., John W. Herron, president of the Ohio Valley Bank, and M. Ferguson, vice president of that institution. The company will employ 150 men or more.

Weekly Review

Soft Coal Market Still Unsettled—Operators Do Not Want Federal Control to Continue After Peace Is Signed—Prices Being Maintained—Production Decreasing—Anthracite Industry in Full Swing—Steam Coal Prices a Little Higher

MARKET conditions in bituminous coal are still unsteady, and production is still falling off. A survey of the situation discloses that large stocks of soft coal are still in the bins of dealers and consumers, and the eagerly awaited buying movement must of necessity wait on the depletion of these reserves.

A plan for the continued Federal control of the bituminous industry after the signing of the peace treaty was opposed by the membership of the National Coal Association at a meeting held in Cleveland recently. The general sentiment of the soft coal operators seems to be that, while a plan of adjustment could have been worked out between representatives of the industry and the Government at one time, the attitude of the Railroad Administration in respect to its coal and steel purchases has made it virtually impossible to reach any agreement at this time. To put it concisely, the soft coal industry has absolutely no faith in the Railroad Administration.

The idea that prices of soft coal would suffer a considerable drop has about disappeared from the minds of many consumers, though there are yet a few who are buying only for their immediate needs in the hope that something will happen to repay them for waiting. These gentry are doomed to disappointment. There is no concerted cutting of prices. Small tonnages may be picked up here and there at figures below the former Government levels, but the better grades of soft coal are bringing even higher prices than were in effect during the fixed-price period.

During the week ended Apr. 19 the bituminous coal mines shipped 7,403,000 net tons, a decrease of 143,000 net tons compared with the output of the week ended Apr. 12. Mines are still working short time, the chief reason being that there is no market for a maximum output.

Anthracite mines, in the main, are working full time. Many operators have booked orders that will carry them well along into June, and retail dealers are delivering coal as fast as they receive it, to meet the call from household consumers. The situation in the hard coal market is almost the reverse of what it was a few weeks ago.

Steam coal is tightening. Instead of price reductions, some of the better grades of buckwheat produced by the so-called independent companies have been quoted at slight increases over what is known as the company schedule. Rice coal is in better demand than either buckwheat or barley. The production of anthracite during the week ended Apr. 19 is estimated at 1,568,000 net tons, a falling off of 182,000 net tons compared to the week preceding.

Consumption and Stocks of Coal in the United States During the First Quarter of 1919

STOCKS of bituminous coal in the hands of industrial concerns, the iron and steel industry and public utilities, gas and electric, declined 25 per cent. or about 8,000,000 tons in the three months from Jan. 1 to Apr. 1, 1919, according to information collected by the Bureau of Statistics and made public by the United States Fuel Administration. Stocks of bituminous coal in the yards of retail coal dealers were 40 per cent. less on Apr. 1 than on Jan. 1, but dealers had on hand Apr. 1 a quantity of bituminous coal one fourth as great as was sold and distributed in the first three months of this year. Such stocks in retailers' yards are considered large for April and are the result of the large accumulations last summer and fall, and of lack of demand the past few months of open winter weather.

The decrease in stocks of bituminous coal in the hands of consumers, including the railroads, in the United States the past three months probably did not exceed 16,000,000 tons. The drop in production of bituminous coal in the same period was 31,000,000 tons compared with January, February and March of 1918.

In proportion to his needs, the small consumer last year was the most successful in accumulating a supply of coal, and by the first of last November every nook and corner of the country was piled with bituminous coal. The small user, industrials using a car of coal or less a month, represents in number 75 per cent. of the total and but 11 per cent. of the consumption. These consumers had on hand last fall 1 per cent. of the bituminous coal in storage, on the average twenty weeks' supply, as compared with the largest users with seven weeks' supply.

With a large supply on hand and the fear of a coal shortage removed, and because of the let-down in manufacturing activity following the armistice and the mild winter, this class of user has been out of the market and will not again seek coal until next fall. Contributing also to the decline in demand has been a decrease in the rate of consumption of coal for industrials other than the iron and steel. The decline is indicated by a drop of 10 per cent. in the average weekly consumption of bituminous coal in January, February and March compared with the latter part of December.

As indicating the sections of the country where abnormally large stocks were accumulated it is noted that the storage piles of industrial plants in Delaware, Texas, Mississippi, South Dakota, Wyoming and Nevada were reduced more than 50 per cent. from Jan. 1 to Apr. 1. More significant, however, is the decrease of from 40 to 50 per cent. in stocks in the region about the Lakes, Wisconsin, Minnesota, Michigan, both upper and lower, Texas, Missouri and Ohio. The same decrease is reported from Georgia, Maryland and Oregon.

Decreases in stocks of from 30 to 40 per cent. are reported for New England and New York in the northeastern section of the country, in South Carolina, Kentucky, Illinois and Arkansas in the Southern and Central States, and in North Dakota. Decreases of from 20 to 30 per cent. are recorded in Pennsylvania, New Jersey, West Virginia, Indiana, Louisiana, Montana, Utah and Washington.

Virginia, North Carolina, Tennessee, Alabama, Florida in the south and Nebraska, Kansas, Oklahoma, Colorado, New Mexico and California in the western part of the United States report decreases in stocks of bituminous coal from 10 to 20 per cent. In Idaho and Oregon the quantity of bituminous coal in storage was not materially changed.

From Pennsylvania and Maryland in the east to Kansas and Nebraska in the west, and in the Mississippi Valley south to the Gulf, excluding the State of Mississippi, but including Florida, stocks in the hands of industrials are sufficient for from three to five weeks. New England reports from 11 to 15 weeks, except New Hampshire with 20 weeks, New York 9 weeks, New Jersey 8 weeks and Delaware 7 weeks. Stocks in the South Atlantic section range from 6 weeks supply in Virginia to 9 weeks in North Carolina, Georgia and South Carolina having 7 and 8 weeks respectively.

The lower peninsula of Michigan has 7 weeks supply, Wisconsin 6 weeks and Minnesota 10 weeks. West of the Mississippi stocks range from 3 weeks in Washington to 14 weeks in Oklahoma.

In about one-third of the states east of the Mississippi the stocks of steam coal in the hands of public utilities increased from Jan. 1 to Apr. 1. Georgia in the south, with an increase of 20 per cent., and Indiana, Kentucky, Ohio, West Virginia, Virginia, Maryland, Delaware and Pennsylvania in the central-eastern section, with increases in stocks ranging from 10 per cent. in Kentucky to 126 per cent. in Delaware, were the states reporting the increases. In the northeastern part of the country the decreases in New York and New England were small, from 3 to 20 per cent.; in the south the largest decrease was 44 per cent. in North Carolina. The largest decreases, more than 50 per cent., were in Wisconsin, Minnesota and South Dakota.

In the aggregate the stocks of bituminous coal held by public utilities decreased but 3 per cent., the decreases in some states having been offset by increases in others.

Coal for gas making in the hands of city gas plants decreased 16 per cent. in the three months ended Apr. 1. Increases in stocks of gas coal were reported in New Jersey, Pennsylvania, Maryland, North Carolina, South Carolina, Georgia, Alabama, Mississippi, Indiana, Michigan and Washington.

Retail Dealers' Stocks of Coal

Stocks of anthracite in dealers' yards were greater on Apr. 1 than on Jan. 1 in four of the New England States, Maine, New Hampshire, Massachusetts and Rhode Island, also in Ohio, in all states south of the Ohio River and east of the Mississippi in Illinois, Iowa, Missouri and North Dakota. The only states east of the Mississippi to report decreased stocks of anthracite in dealers' yards are Vermont, Connecticut, New York, Pennsylvania, Maryland, Delaware, Indiana, Wisconsin and Minnesota. New Jersey and West Virginia report no change in quantity on hand.

Excepting only Alabama, Montana and Idaho, every state reported decreases in stocks of bituminous coal in dealers' yards. Notwithstanding this, the quantity of bituminous coal on hand Apr. 1 was equal to one-quarter the total sold and distributed in the three months preceding.

Stocks of bituminous coal held by plants engaged in the manufacture of iron and steel decreased 24 per cent. from Jan. 1 to Apr. 1. The largest decreases were in coal for use in byproduct coke ovens, 31 per cent. decrease in stocks of high-volatile and 33 per cent. in stocks of low-volatile. Gas-coal stocks decreased but 5 per cent. and steam-coal stocks 17 per cent. The stocks of high-volatile byproduct coal on Apr. 1 were sufficient for nearly three weeks' operation, those of low-volatile for four weeks Stocks of gas coal were sufficient for six weeks and of steam coal for seven weeks

Stocks of gas coal at steel plants in Pennsylvania were increased from January to April by 250 per cent., but in all other states were decreased. Excepting Alabama, stocks of steam coal were decreased in all states. New York, Pennsylvania, Michigan and West Virginia reported slight increases in stocks of high-volatile byproduct coal but decreases in low volatile; in other states reductions in storage of both grades of byproduct coal were the general rule.

The production of coke, both byproduct and beehive in January, February and March, 1919, is estimated at 12,738,700 net tons, an increase of 307,000 tons or 2.5 per cent. compared with the first quarter of 1918. Byproduct coal increased from 5,321,600 tons in the first quarter of 1918 to 6,779,500 tons in the first quarter of 1919, a gain of 27 per cent. Beehive coke recorded a decrease from 7,110,500 tons in the first quarter of 1918 to 5,959,100 tons the past quarter, a drop of 16 per cent. The transition from beehive to byproduct is indicated by the increase in the capacity of byproduct ovens completed, from 6,793,251 tons on Apr. 1, 1918, to 8,576,489 tons on Apr. 1, 1919, an increase of 26 per cent. Since April, 1918, production of byproduct coke has been begun in Colorado and in Rhode Island, and considerable increases in capacity have been made in Maryland, New York, Ohio, Pennsylvania, Tennessee, West Virginia, Wisconsin, Alabama, Illinois, Indiana and Kentucky.

The decrease in the production of beehive coke in the first quarter of 1919 compared with 1918 in Pennsylvania was 5 per cent., as against a decrease of 40 per cent. in all other states.

WEEKLY COAL PRODUCTION

The production of bituminous coal in the United States during the week ended Apr. 19 is estimated at 7,403,000 net tons, and is a decrease of 143,000 net tons compared with the output during the week ended Apr. 12, estimated at 7,546,000 net tons. During the same week of 1918 the operators of the country produced 11,044,000 net tons, and in comparison the current week's output is 3,641,000 net tons, or 33 per cent. lower. For the calendar year to date the output is now estimated at 128,389,000 net tons, as against 166,352,000 net tons during the corresponding period of last year, a decrease of 37,963,000 net tons. This tremendous falling off is better illustrated by comparison of the daily average production—1919 to date, 1,366,000 net tons, and for the same period of last year 1,770,000 net tons. During the current week the daily average is estimated at 1,234,000 net tons, showing that production is continually on the downward grade.

The production of anthracite in the United States during the week ended Apr. 19 is estimated at 1,568,000 net tons, as compared with 1,750,000 net tons during the week ended Apr. 12 and 1,870,000 net tons during the corresponding week of 1918. The daily average per working day during the current week is estimated at 261,000 net tons, as compared with 237,000 net tons for the calendar year to date and 312,000 net tons for the same period of 1918. The total production for the period Jan. 1 to Apr. 19 is estimated at 22,261,000 net tons, as against 29,304,000 net tons during the corresponding period of last year.

Bituminous coal shipped from tidewater harbors to all points during the week ended Apr. 19 is estimated at 405,117 net tons and falls behind the tonnage shipped during the week ended Apr. 12 by approximately 79,000 net tons. Shipments during the current week were but 50 per cent. of those in the corresponding week of last year, 800,312 net tons. A falling off occurred in the tonnage loaded at all the harbors during the current week, with Hampton Roads falling behind the most—40,000 net tons.

Shipments of bituminous coal to New England by tidewater during the week ended Apr. 19 are estimated at 79,491 net tons, as compared with 117,478 net tons during the week ended Apr. 12 and 232,458 net tons during the corresponding week of 1918. The decrease during the current week is due to a falling off in the tonnage loaded at both New York and Hampton Roads. In New York the decrease amounted to approximately 12,000 net tons, and Hampton Roads to 28,000 net tons.

The production of beehive coke in the United States during the week ended Apr. 19 is estimated at 394,912 net tons, and while but slightly less than the 318,630 net tons produced during the week ended Apr. 12, was approximately 200,000 net tons below the output of the corresponding week of 1918. Decreased production occurred in all states during the week of Apr. 19, and in Pennsylvania the current week's output was but slightly more than 50 per cent. of the production during the week of Apr. 20 of last year. All other coke-producing states are far behind the records of the spring of 1918, and for the calendar year to date the output in the United States is 1,900,000 net tons below the output of the same period of last year, recorded at 8,835,956 net tons. The daily average per working day during the current week is estimated at 49,152 net tons, as against 73,824 net tons for the period Apr. 1 to date.

The production of byproduct coke in January, February and March, 1919, was 5,321,600 net tons, an increase compared with the same period of 1918 of 1,457,800 tons, or 27 per cent. In the same periods the production of beehive coke decreased 16 per cent., the net result being an increase in total coke output of 306,500 tons, or 2.5 percent. In the year from Apr. 1, 1918, to Apr. 1, 1919, many new byproduct ovens were completed, the increase in capacity having been 26 per cent. Production of byproduct coke began in Colorado in July, 1918, and in Rhode Island in February, 1919. New ovens were completed in Maryland and New York, beginning in March, 1918; in Ohio the plant of the American Steel and Wire Co. began operation in May, 1918; the National Tube Co. at Lorain and the Ironton plant of the Solvay Co. began to produce in August, 1918; increases in capacity were made during the year at the Portsmouth plant of the Solvay Co., the Toledo Furnace Co. at Toledo, and the Youngstown Sheet and Tube Co. at Youngstown, Ohio. The plant of the Hamilton-Otto Coke Co. suspended about Feb. 1, 1919.

In Pennsylvania the Clairton plant of the Carnegie Steel Co. began operation in June, 1918, and the Steelton plant of the Bethlehem Steel Co. was enlarged. The plant at Chattanooga, Tenn., was enlarged, likewise the Follansbee, W. Va., plant of the La Belle Iron Works and the Benwood, W. Va., plant of the Solvay Co. Plants at Milwaukee and Mayville, Wis., were enlarged, the number of ovens at the Ensley, Ala., plant of the Solvay Co. was increased. Additions were also made at the plants of the Solvay Co. at South Chicago, the Gary, Ind., plant, the Indiana Harbor plant of the Inland Steel Co. and the Ashland, Ky., plant of the Solvay Company.

It is significant of changed conditions that the percentage of capacity attained in production was about the same in the first quarter of 1918 and 1919, but that the losses in 1918 were due to lack of coal and in 1919 to lack of market

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running slightly less compared with the same week last year. Many merchants were in the market and all report a continuance of excellent retail business. The firm tendency of the market has stimulated road business and orders for both immediate and future delivery were in considerably larger volume than same period last year. Collections are satisfactory.

Dry Goods Economist—The labor situation is far from satisfactory. Some of the strikes that have threatened to interfere with the country's business have been called off. On the other hand, certain organizations of workers are presenting new demands which, unless modified bid fair to cause disruption of present producing plans, and prominent among these are the unions of coat and suit operatives in New York. Where strikes have been settled the shorter hours granted to the workers have resulted in curtailed output.

American Wool and Cotton Reporter—Prospects of prices for wool in the West seem to constitute the principal interest in the wool trade at present, other than that manifested in the wool auctions. It is reported that 50c. is being paid the grower for the higher grades of staple wools in Michigan. Prices which are paid in the West are high, compared with those paid at the auction for similar grades of wool. There is no special new feature in the cotton market at the present time, except that if anything it is in a more favorable position.

The Iron Age—The open market that has existed recently in steel products has not been generally recognized because it did not show widespread and sensational price cutting. The industry, without any concert, has been limiting operations to the business coming in. In the past week that has meant further shutting down of blast furnaces and curtailment of working time at steel works. Generally a 50 per cent. operation or somewhat less is indicated among independent companies. The Steel Corporation is on a 70 per cent. basis in the Chicago district and is nearer to 60 per cent. in Pittsburgh and the Valleys.

Atlantic Seaboard

BOSTON

No perceptible improvement. Prices all-rail and at tidewater unchanged. Railroads have not yet made purchases. Low prices rumored on inferior grades. Quality coals being firmly held, except for spot orders. Steamers attracted by high rates offshore. All-rail shippers optimistic. Hampton Roads factors have little business in sight. The few orders in the market are eagerly sought. Anthracite demand strong. Shipments very little better than in 1918. Retail trade brisk.

Bituminous—The past week has been without any notable development in steam coal. It is hard to find signs of improvement in a market such as we are now struggling through, but undoubtedly each week sees some progress made. Heavy accumulated stocks are gradually being worked down and there are still consumers who will be obliged to enter the market before many weeks for more or less comprehensive tonnages. The whole territory is being as closely canvassed as at any period in the trade, and the few buyers who seem interested are quickly made to feel that spot orders are highly prized.

Prices have lately shown almost no variation. For contract all-rail the higher grades are held right around $2.95 per net ton at the mines, but a large number of coals from the South Fork district in central Pennsylvania are being offered at $2.75 @ 2.85. On coal from the Fairmont district there has been a wide range of price, but most of the low figures quoted are because of the restricted outlet here for coals of that region. Except on the New Haven road all-rail rates are against them, and aside from locomotive fuel the demand is relatively small for high volatiles. At tidewater there has been no change in coastwise freights, and except for some oscillation as to f.o.b. mine prices the Pocahontas and New River shippers find their situation practically unaltered. Under the peculiar conditions that prevail this year they find their market closely confined to plants within a short radius of distributing points like Providence, Boston and Portland. Their on-car basis is so high that when the rail charge inland is added the differential in favor of all-rail coals is so pronounced that little room is left for argument.

Contrary to expectation, the last of April has arrived without any contracts of large tonnage being made by the railroads. In nearly every case the New England railroad buyers have invited bidders to revise their proposals, and as yet no action has been announced. It is understood that several shippers have not changed their bids, and it is doubtful whether the Government management has accomplished anything by these moves. The trade continues to be much interested in railroad fuel developments, for in this section of the country it almost seems as if these orders were about the only ones left to worry about. With these long-deferred purchases out of the way it is felt there would be more stability to the market, even if current demand is light.

Rumors of low prices submitted to the railroads have of course had their effect upon the spot market. Scattering sales have been made by middle houses at $2.25 per net ton, but such quotations are on coals that can be used with automatic stokers, and where the saving of 10@15 per cent. in price alone is a consideration. There is less low-priced coal offering over the New York piers than was the case a month ago, due doubtless to the costly experience of many of the smaller shippers during February and March.

The fancy coals, however, are being firmly held, especially for contract. A two to three day a week basis of mining leads some of the operators to make concessions for May and June delivery, but seldom is more than 15c. considered necessary. The higher grades are making inroads on Pocahontas and New River trade, and their worth is being demonstrated. Buyers who have long been consistent users of West Virginia smokeless coals are trying out several of the quality coals from Pennsylvania and the tonnage of the latter is going to show relatively a large increase.

Coastwise freights from Hampton Roads have apparently struck their level, at least for the present. The rates of $1@1.15 from New York to ports on Long Island Sound will have a strong tendency to keep barge freights from Norfolk on the present $2 range, while for steamers there are very attractive offers being made offshore. On a monthly basis charters to South America and elsewhere are such as to leave the present coastwise rate of $2 wholly in the shade. It is hard to say, therefore, what would be the state of things should there suddenly develop a demand in New England for the smokeless coals. The fact is, however, that the market here is not likely to be any broader than it is at present and offshore business will continue to absorb bottoms that were built for the New England coal trade.

Bituminous prices at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net ton as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@$2.75	$2.80@$3.35
Philadelphia, gross tons	4.20@ 4.90	5.00@ 5.40
New York, gross tons	4.50@ 5.25	5.35@ 5.80
Alongside Boston (water coal), gross tons	6.10@ 6.85	6.90@ 7.65

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.69@5.14 f.o.b. Norfolk and Newport News, Va., both for spot coal and for contract. Alongside Boston the present gross ton range would be $6.85@7.50. Season prices have been made at $7.90 on cars, Boston, for inland delivery, but with few sales reported.

Anthracite—The demand for domestic sizes is very strong, with no indication of any easing up for months to come. All the shippers seem well supplied with orders, and for stove and chestnut especially there is an insistent call. The transfer of the Reading fleet of barges and tugs to Port Richmond, Philadelphia, has at last been accomplished, and it is very much hoped that all the delays that were incident to the movement of these barges from Port Reading are now things of the past. Retail dealers along the coast are now hopeful that this long-awaited move will speed up the movement, and that in May coal will come forward in much better volume. While April figures are not yet in hand, it is apparent that receipts here are little, if any, better than in April, 1918, although dealers have been able to secure better assorted cargoes.

From all directions reports are very favorable as to retail trade. The public seems ready to accept present prices, and dealers are being flooded with orders.

NEW YORK

Anthracite moving rapidly. There is much activity in all branches and dealers look for a busy season. All sizes bringing full prices, with some shippers asking slight premiums for some of the steam sizes. Bituminous situation unsettled, because of slow buying and belief that lower prices will prevail.. Anthracite domestic sizes advance 10c. per ton.

Anthracite—With the mines, in the main, operating nearly full time, many operators having sufficient orders ahead to carry them into June and the retail dealers delivering coal as fast as they receive it, the industry is doing nearly all that can be expected of it at this season of the year.

The present condition of the trade is almost the reverse of what it was a few weeks ago. At that time the dealers were doing almost nothing and expected a dull season for the early summer, to be followed by a rush. However, the public suddenly awoke to the fact that the producing companies were not going to make the usual spring reduction, but that in its place there would be a monthly increase of 10c. per ton for five months, which in itself will make the wholesale price of coal 50c. a ton more on Sept. 1 than it was during April. In addition there is likely to be a further increase due to the advance in wages given the harbor boatmen, which will have to be met by the retail trade so far as it affects coal deliveries.

The public is buying on a good basis, but not as heavy as it did a year ago, which is due to the mild winter. The weather conditions during April resulted in heavy consumption and there were many one- and two-ton orders. The dealers are hopeful that the public will take advantage of the present state of the industry and place its orders for next winter's supply early.

The trend of the improvement can be seen in the record of dumpings at the local docks during the week ended Apr. 25, 5288 cars having been dumped as compared with 4595 cars the previous week, an increase of 693 cars.

The ending of the strike of harbor boatmen caused a flurry in shipments for a few days, but conditions soon became normal. There has been an increase made in water freight rates and boat-owners are as a rule asking 50c. per ton for deliveries in the harbor limits.

Reports from inland dealers show that in this vicinity they are carrying smaller stocks than they had in the early part of January, while throughout New England conditions are just the reverse.

Inquiries from Canadian dealers are numerous. Supplies are badly wanted and orders are generally accompanied by a request that the coal be hurried forward.

The anthracite steam coal maket is gaining strength. Demand is heavy, and instead of an easy price situation some of the better grades of the so-called "independent" buckwheat coal are said to have been quoted at slight advances over the regular company schedule. Rice is in better demand than either buckwheat or barley.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports are as follows:

	Mine	Company Circular
Broken	$6.05	$7.90
Egg	5.95	7.80
Stove	6.20	8.05
Chestnut	6.30	8.15
Pea	4.90	6.65
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The market is unsteady due to the disposition of some buyers to delay stocking up. There is a belief among many buyers that there is going to be a drop in prices, and at any rate they are willing to take a chance on being able to pick up sufficient coal in the open market at lower than present prices to keep them supplied.

The settlement of the harbor strike did not improve delivery conditions to any extent. There was considerable congestion at the docks following the ending of the strike because of the apparent desire of every dealer to get his boat loaded first, with the result that there was more or less delay in getting boats loaded and then towed.

Bunker coals are in better demand than the commercial coals. Many ships come and go daily, and producers and shippers with a heavy bunkering business find themselves rushed with orders for immediate delivery. In many instances ships were loaded on Sunday, so strong was the demand for immediate coaling.

The lack of demand is attributed to the fullness of many consumers' bins, even though local shipments were slackened for several weeks. The local piers are well stocked with coal, due to the lifting of embargoes followed by increased shipments from the mines.

Stocks in the hands of consumers in the northeastern section of New York State are said to show a heavy reduction from the early part of January, but even at that it is estimated that the stocks on hand are sufficient to last for from 7 to 9 weeks. Much better reports come from New England, where large consumers are carrying heavier stocks.

There has been a slight decrease in quotations for loaded boats alongside, these ranging from $5.75 to $6.75 in some instances. Quotations covering the general range of coals show a slight decline for some grades, but they are small and of little consequence.

The report of dumpings of bituminous coal at this harbor for the week ended Apr. 25 shows an increase of 851 cars over the number for the previous week.

Quotations for the various grades of bituminous coal for spot delivery or on contract range about as follows:

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.80 to 3.10	2.95 to 3.25
Clearfield County (good grades)	2.65 to 2.95	2.80 to 2.95
Reynoldsville	2.50 to 2.75	2.75 to 2.95
Quemahoming	2.75 to 2.95	2.95 to 3.10
Somerset County (best grades)	2.75 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.25 to 2.50	2.50 to 2.75
Western Maryland	2.25 to 2.75	2.50 to 2.75
Fairmont	2.10 to 2.35	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.35 to 2.40	2.35 to 2.60
Westmoreland ¾ in.	2.60 to 2.75	2.60 to 2.75
Westmoreland run-of-mine	2.35 to 2.60	2.35 to 2.65

PHILADELPHIA

Anthracite activity continues. Heavy orders booked by all shippers. Stove in greatest demand, with nut close second. Pea improves, but still plentiful and troublesome. Strong advertising campaign helps trade. Retail price situation fairly firm and improving. Steam sizes in fair shape only. Some shadings on the smaller sizes. Mine prices on family coal up 10c. Bituminous unimproved. Consumption light. Condition fair at tide. Rail price still in abeyance.

Anthracite—A continuation of the great activity that began two weeks ago is reported from the offices of all the big shippers. Several individual shippers report that they are booked for heavy tonnages two months in advance. It is a fact that no operation of any reputation seems to be lacking in orders for egg, stove and chestnut. From some of the larger shippers it is learned they are practically sold up for May, and that no new business is being taken except subject to a delay of at least thirty days.

All shippers report that many orders for stove, and quite a few for chestnut, will remain unfilled for April. Pea, too, is stronger, but it can still be shipped fairly promptly, and some of the smaller operators are said to be offering it at less than company price. It is believed also that a few of the individual shippers are insisting that their customers, for stove coal particularly, also take a certain quantity of pea.

It is quite apparent that the shippers are assuming a more cheerful attitude, particularly the large operators, and the good demand for coal is general throughout the country and it is becoming evident that good business will continue much later than anticipated during the dull days of March. The demand for family sizes continues unabated from the West where the consumers seem bent upon making up for the coal that was denied them last year.

Retail prices can be said to be held quite firmly, and the cutters have had no increase to their number. In fact a number of the lower-priced dealers are expected to advance their rates any day, especially as their stocks of pea coal run down and they begin purchasing at the new figure. It will be remembered that the principal drive of the cutters has been on this size, most of which was purchased at a lower figure than the new circular. All representative dealers continue to charge $10.30 for egg, $10.55 for stove, $10.65 for chestnut, and $9.05 for pea, per ton of 2240 pounds.

As business improves so do collections, and as the retailers are enjoying a fair margin at the above rates, the shippers are again growing more particular about extending credits.

With the larger sizes in such active demand, it is to be regretted the spurt has not as yet reached the steam trade. The big companies continue to store buckwheat, but it is the opinion of at least some of the shippers that industrial conditions are sure to improve before this size is produced in excess of the demand and the capacity of the storage yards. Certain it is there are bound to be very serious difficulties if the demand for egg, stove and nut keeps up, with no corresponding demand for pea and smaller sizes. As to prices some of the smaller shippers continue to offer buckwheat around $3, and we have heard of some sales as low as $2.85. Rice is actually reported by some shippers as stronger than buckwheat, but is still selling for $2.25 to $2.50. The latter is probably close to the average. No one reports barley except as being in less demand than either buckwheat or rice, and we are told that sales are recorded $1 per ton less than the circular, or $1.25.

As announced when the spring price circular was issued, the mines prices advanced 10c. per ton on May 1, making the prices per gross ton for line shipment and f.o.b. Port Richmond for tide as follows.

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	5.95	7.80	Rice	2.75	3.65
Stove	6.20	8.05	Boiler	2.50	3.50
Nut	6.30	8.15	Barley	2.25	3.15
Pea	4.90	6.50			

Bituminous—Practically no one in the trade is willing to admit that there is any real improvement in business. Production is off as compared to last year at this time, and few operations are working more than half their capacity. The market is simply unable to take any more than a moderate tonnage. While in ordinary years most plants were storing coal at this time, now most of them are anxious to reduce stocks on hand.

At tide there is a fair volume of business, but principally bunker trade. Even this is not as heavy as in the past, as the ships are gradually resuming the practice of bunkering only for one way instead of for a round trip as became the custom during the war. The coastwise trade remains quiet, with rates still high.

There has been no adjustment of the railway fuel controversy and it looks like a waiting game on both sides. The operators seem to have reached their limit in submitting prices to the railroads only to have them rejected.

Despite the rather inactive market, prices continue to rule fairly firm. The following are fairly representative of the figures ruling lately:

Georges Creek Big Vein	$3.00 @ $3.10
South Fork Miller Vein	2.90 @ 3.10
Clearfield (ordinary)	2.75 @ 2.90
Somerset (ordinary)	2.55 @ 2.70
Fairmont lump (ordinary)	2.40 @ 2.50
Fairmont mine-run	2.20 @ 2.35
Fairmont slack	2.05 @ 2.20

BALTIMORE

Market slowly settling into more normal condition. Inquiries increasing. Hard-coal schedule for April to be continued through May for retail purchasers. The export situation.

Bituminous—The government departments, including the Railroad Administration, are now seeking contracts on both yearly and monthly deliveries. A number of the larger industries in this and nearby sections are also sending out contract inquiries, and the general situation as to soft coal seems to be shaking down to normal. More contracts are being made now, and there is a growing inclination to get under cover.

For best grade coals the contract prices are still being held firm at the old Government maximum rates, or better; for the less desirable coals there is more of an inclination to shade, and some of those who had announced that they would not let go of their product below the Government schedule are now making contracts to supply customers at from 25c. to 50c. off the figures they first set. This inducement is bringing consumers under cover where they held out when the spot prices benefit was probably double that of the latest cuts on contracts. Within a few weeks it is predicted that the spot prices will have come up about level of the present contract prices, and that many more contracts will be recorded.

The trade believes that later in the summer both the spot and contract prices will be decidedly higher than the offerings to consumers at present. The export movement the past week was but fair, dropping considerably behind the week previous. There was exported in four bottoms a total of 12,840 tons of cargo bituminous; 908 tons for bunker use, and 90 tons of anthracite for cargo.

Anthracite—Announcement is made here that the April schedule for hard coal at retail, which was 40c. off the last winter prices, in addition to an allowance of 25c. per ton for cash within ten days of delivery, is to be continued throughout May. The same schedule may be held until July 1, if there is no freight rate or other unexpected increase. The retail trade is taking orders at the existing price where consumers tell them bins are ready for coal at once; and at the price at time of delivery if the order is placed now subject to later notice as to delivery. The supplies here were not enough to meet the rush of orders that followed the April price cut, and the dealers expect to be pretty busy all through May.

Lake Markets

PITTSBURGH

Sentiment somewhat improved. Reduction in stocks. Decreasing consumption by steel industry.

Sentiment as to market prospects is much improved in Pittsburgh coal-producing circles. While there has been but little improvement in actual demand, there is progressive diminution in stocks in the hands of consumers, and the heavy part of the lake shipping season is neared by another week. In connection with stocks, there has been considerable discussion of the Fuel Administration's statement as to reduction in stocks during the first quarter of the year. Stocks of bituminous coal in the hands of industrial concerns, the iron and steel industry and gas and electric public utilities, decreased by 25 per cent. or by 8,000,000 tons.

Such a statement may be regarded as favorable or unfavorable according to the viewpoint. If the objective were the elimination of such stocks, little progress was made if the reduction in three months, winter months at that, was only 25 per cent. On the other hand, however, it is pointed out in the trade that practically all these consumers carry stocks, and the iron and steel industry, when facing a period of activity, particularly in the fall, counts upon having large stocks.

A feature of the situation encouraging to operators is the manner in which prices are being maintained. Such shading as occurs is confined almost entirely to spot lots or short term deliveries, say to July 1 at the outside. Even spot lots do not evince much softness. Steam coal has sold down to $2 of $1.90, but only in special cases, and many of these are of operators who but recently entered the ranks of producers and for financial reasons must maintain production.

The steel industry's coal consumption is decreasing, with lighter steel production each week. The leading independent in the Pittsburgh district is operating at only 45 per cent., while the independents in the Youngstown district are running 50 to 65 per cent. The Steel Corporation subsidiaries in the two districts are operating at 65 to 70 per cent. The tin plate industry, a large coal consumer in proportion to its tonnage output, is doing only about 55 per cent., but will probably be running full in the summer.

There is a little more activity in byproduct coal. Sales running from spot to deliveries over a few weeks have been made at down to $2.10, but it is doubted whether $2.35 could be shaded materially on a year contract. Disregarding occasional cut-price transactions the market is quotable as follows: Byproduct, largely nominal, mine-run, $2.35; high-grade gas coal, slack, $2.10@2.20; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.70; steam, slack, $1.90@2; mine-run, $2@2.35, all per net ton at mine, Pittsburgh district.

TORONTO

Dealers very busy. Domestic consumers rushing orders before price goes up. Stocks in yards light. Fears of a coal famine next winter. "Coal Club" cannot buy at wholesale prices. Bituminous still quiet.

Dealers are very busy, as the consumers of anthracite, who have for some time been withholding orders in the vain expectation of some reduction in price, are now buying freely. A touch of chilly weather, combined with the prospect of an increase

in price, has stimulated the movement; and something like a rush has set in. Stocks in the yards are low and shipments from the mines comparatively light since the setting in of navigation, much of the supply being diverted to the upper lakes

H. A. Harrington, Deputy Fuel Controller for Ontario, has issued a warning to the public that the province may expect a coal famine next fall and winter unless people lay in their supplies at once. He further gives figures to show that not only will consumers have difficulty in getting coal, but that the price next fall will go up to about $14 per ton, as at present there is an actual shortage of coal. A number of citizens organized a "Coal Club" with the object of buying their coal for the winter in carload lots at wholesale prices in Buffalo, paying their own freight and haulage charges here. Their representative visited Buffalo and interviewed the dealers who refused to sell to him, saying that they had agents in Toronto and would not deal with private individuals.

The demand for bituminous continues light, as there is little change in the industrial situation with a slight reduction in wholesale prices.

Quotations for short tons are as follows:

Retail:	
Anthracite egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	8.25
Slack	7.25
Domestic lump	10.00
Cannel	11.50
Wholesale f.o.b. cars at destination:	
Three-quarter lump	6.00
Slack	4.75@5.00

BUFFALO

Bituminous decidedly quiet. Car shortage in grain trade looks ominous. Settling the freight prepayment demand. Anthracite moving steadily.

Bituminous—The surplus of slack still vexes the market. This condition was not unexpected, as it happens regularly when the lake trade opens; but now it comes at a time when the trade is staggering under the load of over-production and adds another strain to the market.

A sudden shortage of cars in the grain trade is attracting attention, as it is something that might easily happen in the coal trade; and when it does the market will stiffen rapidly. Jobbers have warned consumers that something of the sort is about due, but no attention is paid to their statements.

The railroads are fixing up the new rule obliging the prepayment of the freight on slack coal going into Canada. A meeting has been held at the office of the Michigan Central R.R., which was attended by coal shippers. The plan is to establish some regular guaranty or insist on full prepayment.

Bituminous prices are not very strong, but figures are the same as last week: $4.65 for Allegheny Valley, except slack; $4.45 for Pittsburgh and No. 8 lump; $4.20 for mine-run, same, and $3.80 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The movement is good. Some shipping agents are behind with their orders for Canadian and rail shipment west, and the supply for lake loading has been cut down materially. The consumer does not want to pay the advance in price and the demand is said to be heavy eastward. If the Canadian retailers were not handicapped with substitute fuel there would be quite a rush for anthracite there.

Lake clearances for the week are 48,000 net tons to Duluth and Superior, 31,700 tons to Milwaukee, 13,574 tons to Sheboygan, 11,917 tons to Fort William and 6600 tons to Chicago. Freight rates are 42½c. to Duluth and Fort William, 50c. to Milwaukee and Sheboygan, 60c. to Chicago.

CLEVELAND

Activity in the lake trade has completely overshadowed the local steam-coal market. Strong in the belief that bituminous coal will be scarce later, operators are crowding shipments forward. Pocahontas has been marked up 25c. by all dealers and 50c. by some. Present prices are believed to be plumbing bottom for this spring.

Bituminous—No. 8 mine-run is to be had here in any tonnage at $2, No. 8 three-quarter inch at $2.10 and slack all the way up from $1.75. But even these attractive prices—attractive, comparatively—are not stimulating business. Nor are No. 8 district operators putting forth very strenuous efforts to sell, for the lake trade is making heavy inroads into production. Generally speaking, the upper-lake dock coal interests stand ready now to take all the bituminous coal operators can forward. While many lake shipments are going forward with the price to be determined later, this business looks alluring to both operators and the dock interests, and the arrangement is mutually satisfactory.

Without exception, all dealers have pushed Pocahontas prices up 25c. a ton, while a few of the larger ones have made the advance 50c. Dealers complain that offers of $3.50 for Pocahontas are spurned, whereas $2.60 before and $2.95 during the war were the market levels. Difficulty of disposing of the slack is making the coarser grades of Pocahontas higher, it is said. Dealers are warning consumers to lay in next winter's supply, and quite fair results are reported. Anthracite is somewhat difficult to move despite the certainty of a 10c. increase May 1 and further advances throughout the summer.

Many No. 8 district mines are reporting labor shortages, a condition just the reverse of that obtaining in eastern Ohio not more than five weeks ago. Belief that the coming summer will see mines operating at close to 100 per cent. is gaining ground. Mine workers who were growing restive have neither the time nor the inclination now, and indeed not the audience, for their dissensions. With the resumption of activity the labor situation has improved greatly.

Lake Trade—Authoritative carrying rates for coal on the Great Lakes this summer finally have been determined. The rate from Lake Erie ports to the head of the lakes—Superior and Duluth—will be 42½c. a ton, compared with 48c. last season. This was the first price arrived at. But instead of a rate of 50c. to Lake Michigan, coal from Lake Erie will be charged 47½c., as against 55c. in the season of 1918. The big lake fuel interests have announced this season's fuel coal will cost $4.35 from car dumpers and $4.85 from lighters, both prices applying at Ohio ports. The charge in the Detroit River and at Lime Island will be $5.50.

Not only do the lake coal interests believe that coal will be scarcer later in the summer, but that cargo space also will be more difficult to get. The iron ore trade is opening up quite slowly, and the end of the season is likely to find ore carriers rushed back to the head of the lakes light. No contracting below $2.35 is reported, with $2.40 still being held up as nearer the correct figure.

DETROIT

Lack of interest among Detroit buyers causes jobbers to fear their efforts to get bituminous coal later may be hindered by shortage of supply.

Bituminous—While a small amount of encouragement is derived by Detroit jobbers and wholesalers from reports that several of the large users of steam coal are cutting down their reserves more rapidly than a few weeks ago, there seems little tangible present improvement in the market. The larger proportion of buyers is exhibiting no interest. A few scattering inquiries appear, but these come principally from the smaller buyers.

Jobbers say that the Fuel Administration prices are being quoted to inquirers considering contract negotiations. These prices also are said to be generally maintained on sales of lump and prepared sizes. Mine-run and slack are proving more difficult to place, and the Government prices have been shaded materially in a number of instances, the reduction on slack amounting to as much as $1 a ton. Price reductions, however, do not seem to stimulate buying. It is the contention of some of the jobbers that the buyers do not so much desire cheaper coal as they do the assurance of stability of prices, to guard against some of their competitors gaining an advantage by placing orders at some later time.

Anthracite—Diligent attempts are being made by Detroit retailers to stimulate an early buying campaign among household consumers. The movement is supported by advertisements placed by the Detroit Coal Exchange. The supply of anthracite now seems plentiful, and buyers are warned that the prices on prepared sizes will be advanced May 1.

COLUMBUS

A slight improvement is noted in the Ohio coal trade. There is a better feeling in steam circles, although the larger purchasers are still holding off on contracts, because of price uncertainty. The lake trade is showing signs of starting.

The steam trade in Ohio territory is more active as a result of some orders and a greater number of inquiries. Though a majority of the larger consumers are still waiting to see the outcome of price developments, some of the smaller users are buying considerable for current needs. The demand for spot shipments is slightly better, and this is reflected on the entire trade. The railroad situation is still unsettled and little railroad contracting is reported. Producers are only mining what their orders call for, and consequently there is practically no overproduction. The worst feature is the slowness of industrial conditions to improve, and consequently there is no increase in fuel requisitions.

The lake situation is slow in clearing up as it is connected with the steam situation so closely. Lake prices are still unsettled, and as a result there is little contracting for lake tonnage. Some agreements have been entered into leaving the price question to be settled at a later date. Some vessels are being loaded and a small movement will start about May 1.

The domestic trade is quiet, and this is one of the drawbacks to the market. There is a good demand for the better grades, such as Pocahontas and splints, but the usual run of domestic tonnage is not moving. Retailers have sufficient stocks for the present and they are waiting, like steam users, to see the price question settled. Little domestic tonnage is moving from Ohio mines. Retailers are urging the public to buy early, but their campaign is not meeting with results.

CINCINNATI

No activity in market at present. All hopes based on future. Board of Education asks for bids on coal.

Leaders in the coal industry here are anticipating a tremendous business boom following three or four months of readjustment, and are making such arrangements as are possible under the unfortunate condititions existing to furnish a greatly increased demand which, coming with a rush as it is expected to do, will in all probability cause a serious coal shortage and consequently higher prices. Wages of the coal miners are very high, and are not expected to be adjusted until peace has finally been declared, when there is more likely to be an increase rather than a reduction.

The Board of Education of Cincinnati will receive bids for coal of the following description: 10,000 tons more or less smokeless run-of-mine coal; 4500 tons more or less nut and slack bituminous coal; 2500 tons more or less lump bituminous coal; 75 tons more or less run-of-mine (bituminous) coal. The specifications for this large contract are on file at the Chief Engineer's Office, at 511 Court St., Cincinnati, Ohio. Each proposal must contain the name of every person interested therein, and must be accompanied by surety company's bond in an amount equal to 30 per cent. of the amount of the bid, as a guarantee that the bid is bona fide, and the bond of the successful bidder or bidders approved and held until final settlement is made. The Board of Education reserves the right to reject any part of any or all bids.

LOUISVILLE

Conditions in the mining regions about the same. Retailers of Louisville reduce prices in order to increase summer stocking. General demand quiet.

The principal feature of the market in Louisville is the action taken by the Louisville retailers following a get-together meeting at the Board of Trade on Apr. 21, when it was decided to reduce May prices in order to stimulate spring and summer stocking. Reductions averaged from 30 to 60c. a ton retail. The retailers adopted the following prices:

	Eastern Kentucky	Smokeless	Western Kentucky
Block and egg	$6.50	$7.50	$5.60
Mine-run	6.25	7.25	5.35
Nut and slack	6.00	7.00	5.10

Anthracite, which is not handled to any extent on this market, was placed on a basis of $12.50 a ton. Eastern Kentucky coal included Harlan, Hazard, Jellico, Straight Creek, Elkhorn, West Virginia river or rail, and all of the high grades from the Cumberland mountain district. On a lump basis Harlan had been selling at $6.75; Jellico and Straight Creek, $7.10; Hazard, $6.65, and western Kentucky, $5.90.

While some objection was raised to the decrease in view of the fact that the mines are making no reductions, still it was believed that it would be much better to get the consumers started on summer stocking, even at a reduction in values, and objections were quickly overruled. However, in the few days since the new prices were announced there has been no material im-

provement in retail demand; but this may be due to the fact that it is near the end of the month.

Mines are holding prices firmly. The mines of the Jellico district are asking $3.25 for block and egg at mine, although some are selling on the same basis as other eastern Kentucky coals. The average range of prices are as follows.

	Eastern Kentucky	Western Kentucky
Block and egg	$2.85@$3.00	$2.60
Run-of-mine	2.30@ 2.50	2.35
Nut and slack	1.90@ 2.10	2.05

While western Kentucky is not doing much price cutting, and is endeavoring to hold prices firmly, a number of the mines are meeting eastern Kentucky competition openly. Some of the eastern Kentucky mines have been slashing prices considerably on mine-run and nut and slack. Most of the mine-run cutting has been done on low grades of badly mined coal, while on nut and slack many mines have been selling at low figures in order to unload it. There has been some spot coal from all of the fields on the market at low prices, but as a whole there has been less price cutting done than had been anticipated.

BIRMINGHAM

Good undertone apparently pervades the market, but material improvement in the steam trade is not noticeable. Domestic contracts have absorbed the anticipated output of many of the operations producing the best grades through March, 1920. Production from commercial mines slightly improves while furnace companies reduce their output.

While there is no noticeable improvement in the steam trade, basic conditions are favorable to a strong demand when the tide does turn, is the way in which well posted coal men sum up the local situation. Prices are reported as firm on the basis of the last Government schedule.

Domestic coal is in strong demand and there is need for every lump that is being produced. Some mines have sold their estimated output through March, 1920; that is, the better grades of fuel, while some companies are not selling to their anticipated capacity. Carbon Hill and Corona, cheaper grades, are also being eagerly sought and a heavy tonnage has been sold. Sales are based on a price increase of 10c. per ton per month through September added to the schedules effective Apr. 1.

Commercial companies are operating on about the same basis as they have been for several weeks past, but furnace companies have closed down many of their largest mines, as iron production is cut down to almost the lowest possible notch.

Coke

CONNELLSVILLE

Market fairly steady. Production better adjusted to consumption. Byproduct coal offered.

There is rather stubborn resistance to further price declines in Connellsville coke. The program of curtailing coke production to fit the circumstances is working out better than a few weeks ago, when operators could not keep track of furnaces about to blow out. Furnaces are still blowing out, but the notice is not so sudden. Conditions are also helped by the exhaustion of stocks at most furnaces and shipments are more regular in proportion to actual consumption.

Many of the coke operators would like to sell coal for by-product purposes, but the opportunities are limited. The regular asking price is $2.35, but many operators would be willing to shade this price by 10 or 15c., in some cases by 25c. In the case of operators with the lightest production it is not a case of choosing which is more profitable, to sell coal or to sell coke, because most operators consider it essential to maintain organizations. Even at $2.10 for coal, the value of the coal for a ton of coke would be $3.15, and when coke is sold at $3.60 there is represented a margin of only 45c., and even with $2.75 coke the 60c. margin is not sufficient to cover the cost of coking. Sales of coke at such prices are made only for special reasons. Operators with a fair rate of operation would not sell at under $4 or $4.25.

Spot and prompt lots of furnace coke have been going at $3.60 to $3.75, the latter being rather a high price on such business, commanded only by the best brands. Brokers assert that they could buy fair grade at $3.50 if they had definite orders to offer, and it is stated that bids at this price have been solicited by a few operators. The regular value, as an adjustment price under contracts, is held to be $4 to $4.25. Foundry coke has softened, ordinary brands that were commanding $4.50 in carload lots now being available at $4.25. One maker of a well-known brand has reduced from $5.25 to $4.75, but some are still holding to $6, in order to protect contract shipments. The spot and prompt market generally is quotable at $3.60@3.75 for furnace and at $4.25@6 for foundry, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Apr. 19 at 148,825 tons, a decrease of 1590 tons.

Middle Western

GENERAL REVIEW

Situation shows improvement. Export of large tonnage of Eastern coal will benefit Illinois and Indiana mines.

The situation in the Middle West market for the past week shows more improvement, and it is being freely predicted that within the next sixty days conditions will become normal, or perhaps a little better than normal. Mines are working more and are recovering slowly from the inactive period they were faced with two or three weeks ago.

News from the East is very encouraring, especially the news to the effect that the Government is going to get behind the exportation of coal, and do all possible toward opening up a market for our eastern coals in Europe, South America and North Africa.

The buying public are becoming more alive to the coal situation, and there has been a decided tendency, within the past two weeks, toward placing contracts. Some steam coal has been moving on the open market, and we understand at very fair prices.

CHICAGO

Activity in shipments and contracts. Domestic movement slowing up, with exception of coal from the East.

There has been some activity in the Chicago market, both on current shipments and on contract. The big news of the week is that the Universal Portland Cement Co., of Gary, Ind., has closed its contract with one of the big operators down in Franklin County. This business heretofore has been handled through the Consumers' company, but this year the Universal people decided to deal direct with the producer. This contract, which has just been closed, is one of and may be taken as a fair indication of the general attitude of the purchasing agents in Chicago.

The domestic situation is lagging a bit, with the exception of the movement of Eastern coals. The dealers believe that if they wish an Eastern coal, they had better purchase it now, and for this reason there is a brisk demand for all Eastern coals, while the demand for Illinois and Indiana coals is dull in the extreme. The Illinois and Indiana miles will come into their market a little later, along about July 15 and after.

MILWAUKEE

Business continues quiet, with everybody waiting for the promised new schedule of prices. First cargoes of the season being unloaded at the docks.

The coal market at Milwaukee has reached a waiting stage. Dealers announce that a new schedule of prices is due May 1 and consumers are holding off till that time. Naturally business is at a standstill. Some dealers think that anthracite will be shaded slightly at the opening, but that the monthly advance of 10c. per ton until September will carry the winter rate to a higher point than that which prevailed in the fall last year. Others hold that anthracite will open higher than present prices. It is hard to comprehend how bituminous coal can be stiffened any, as stocks on hand are fairly liberal and new consignments are arriving. Four good-sized cargoes have reached port since Apr. 20, and daily arrivals can be expected from now on. Coke is held at top figures, but stock piles are increasing.

ST. LOUIS

Nothing unusual to change the aspect of the local situation. Practically no contracts being signed up or arranged for, and an exceptionally small tonnage moving on all kinds of business.

The situation in the St. Louis territory continues exceedingly quiet. This is usually the season of contracting, but up to the present few contracts have been made for either carload or wagonload coal in St. Louis.

The local demand is extremely easy. There is a little coal of the cheaper grades for domestic business in small lots. It is so small, however, that it has no effect on the market.

In a steam way, the market is much quieter than is usual in this season. Manufacturing seems to be almost at a standstill judging from the condition of the screening market, which ordinarily would cause an unusual demand for screenings at this time. It is true that screenings are in good demand right now, but not to the extent that it has brought about any marked change in the price. This pertains to all fields.

There is a little anthracite moving for domestic storage and a little coke, but nothing in the way of smokeless or Arkansas.

Some mines are working a day or two a week and others are idle. The movement of coal as far as transportation is concerned is good. There are plenty of empties.

In a general way the districts are not any worse than is to be expected in view of the business situation all over the country.

COAL AGE

Volume 15 New York, May 8, 1919 Number 19

Four Instead of Two

By Floyd W. Parsons

N the days before the war, the business men of America were noted for their initiative. Individuality was the common virtue of most of our citizens. After we entered the fight, it was soon apparent that to be most effective as a people we must act as an organized unit, giving strict obedience to the Nation's leaders.

The result was that we formed the habit of looking toward Washington for all guidance; and the trouble is that we continue to seek marching orders in the Nation's capital. If we are to again go forward as of old, something must be done to restore in part the spirit of personal adventure. The individual must again be encouraged to think and act for himself.

To believe that we will return to the prewar days of selfish indifference is a false conclusion. There will never again be such independence of action. But extreme parental control is a condition no better than extreme individualism.

One of the chief troubles today is that so many people believe humanity can be governed by the application of doctrines that are logical. But this is a false premise. Germany's ruin was caused by her endeavor to base her future on a course of procedure founded on logic. Teuton leaders have learned too late that there is a difference between machines and men. Common sense is far better than logic in the treatment of problems that deal with the impulses and passions of human beings.

It is this same common sense that will save us in these serious days, when the chief impulse of man is to critically examine all human institutions. In Russia the mistake was made of rejecting the traditions that had survived the fires of scores of centuries. Property, religion and marriage—oldest of institutions—were set aside, and we know now better than ever before that such traditions cannot be broken down without at the same time leveling all other institutions on which civilization is founded.

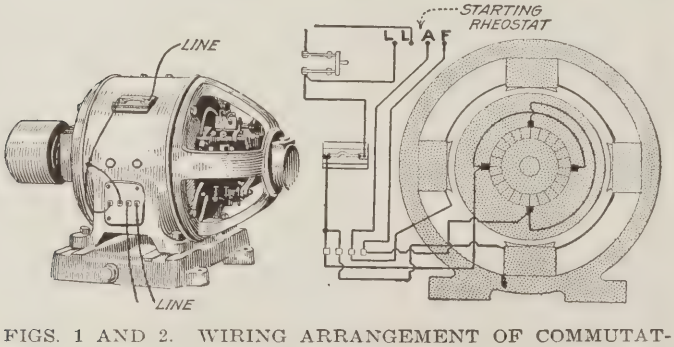
This does not mean, however, that present systems are wholly correct. We must have greater elimination of caste. Even here, in this free country, where there are no kings and princes to annoy us, we might add still more encouragement to the plan of awarding recognition to men in proportion to the services they render. In the coming years the definite tendency must be to further and further restrict the advantages that come to individuals simply because they are smart, not because they are able.

No future government can succeed unless it is based upon a system in which brains are pre-eminent over capital. More and more will we standardize the return from invested money. More and more will we regulate the margin above interest that is allowed as insurance to those who undertake ventures that are attended by risk. Once capital was the prime party to industry; now there are three others —labor, management and the public, or rather the state. The day is not far away when we will abandon the idea that capital and labor are the only parties concerned.

Just what machinery can be devised to satisfy the combined interests of this quadruple alliance is not now known. Only by careful experiment can we find the answer. Capital must be safeguarded, financial adventures encouraged, labor fully recognized and permitted self-expression, brains adequately rewarded and the public protected. Let us not have patience any longer with talk about fights between capital and labor, as if they were the only parties interested.

IDEAS AND SUGGESTIONS

Hot Air for Pumping



It is correct practice to cool air as it comes from the compressor and so deposit much of the moisture which may be in it. Moreover, the cold air occupies less space and so goes more readily through the air lines. It is going to be cooled on the journey, and the sooner it is cooled the better. For this reason, it is customary to cool it at the receiver even when the purpose is to reheat it before use.

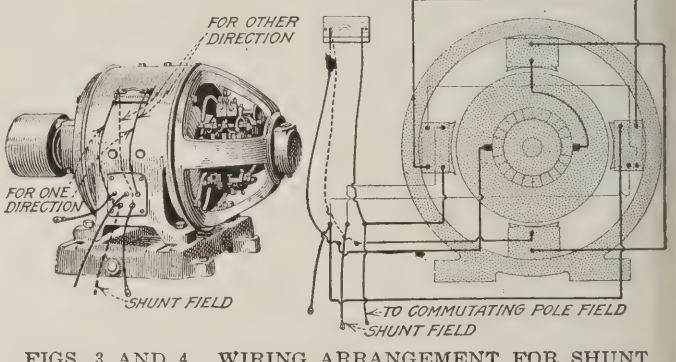
When, however, the air is only to be taken a short distance, say, a few hundred feet, it is well to put nonconducting material around the pipe, taking the air off the discharge line before it is cooled. At its high discharge temperature it is quite dry and can be used economically in the pump or other air cylinder. This will sometimes save a reheater where the pump is in a place where the cold normally causes freezing. If the air is taken to a receiver and so allowed to cool, it is of course no use to spend money to protect the line except, perhaps, the expense for burying the pipe.

Protecting Small Motors

By J. J. Nolan
Linton, Ind.

The difficulty encountered in protecting small motors in remote parts of coal mines with some suitable and yet not too expensive or elaborate device to prevent burnouts of armature or fields, or sometimes both, has

FIGS. 1 AND 2. WIRING ARRANGEMENT OF COMMUTATING-POLE MOTORS



led the company with which I am connected to equip 200 motors, ranging from 5 to 15 hp., with fuse blocks of a type similar to those pictured in Figs. 1 to 5.

When being overhauled in the repair shop each motor is equipped with a block, as shown, and ten extra fuses are fastened securely on the motor for future replacements. A reserve supply of each size is kept on hand, to be sent out as ordered.

Fuse blocks have been installed on most of the motors remaining at the mines by getting a list of different sizes and sending or taking out the number and sizes required. The work then requires only the drilling and tapping of four holes; the block is fastened on and connected as shown.

I have noticed a decrease in the number of serious burnouts since this plan has been in effect. Those in charge of motors in the mine often pay too little attention to this important equipment by trusting in Providence and a little oil once in a while. The company, of course, foots the bill, and occurrences like those mentioned above usually excite no comment.

The wiring arrangement on the commutating pole types of motors shown in Figs. 1 and 2, if properly

FIGS. 3 AND 4. WIRING ARRANGEMENT FOR SHUNT TYPE OF MOTOR

connected, causes the current to pass through the fuse. The reversing connections are easily made (see the dotted lines) should it be desired to reverse the direction of rotation. The wiring arrangement for the simple shunt types shown in Figs. 3 and 4 are somewhat different, as the terminal of the fuse block is reversed for the line wire. Reversing is done below, as shown.

Should the oiling of a motor be neglected, and hot bearings develop that might cause it to stop, the fuse should protect it from serious damage as well as other troubles that might cause heavy overload.

The length, width and thickness of ribbon to use were

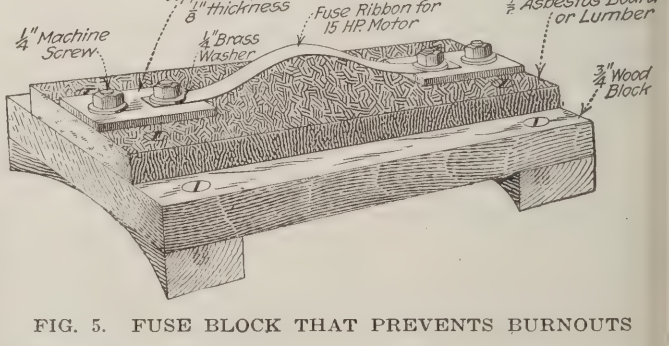


FIG. 5. FUSE BLOCK THAT PREVENTS BURNOUTS

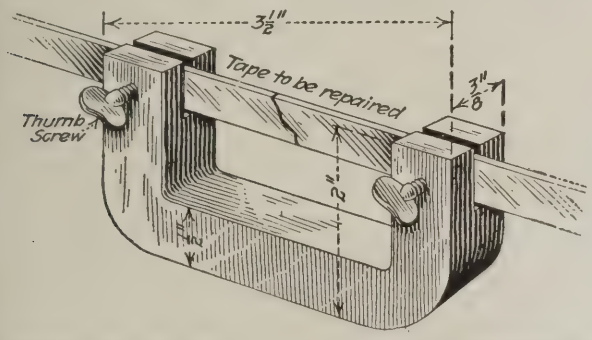

all decided after thorough tests were made for each size of motor. The ribbons employed allow the motor to start under load without blowing the fuse and yet offer protection on any undue continued overload. The connecting and reversing arrangement of connections shown was worked out with a view to its being of assistance to anyone who might be connecting or have

occasion to reverse one of these motors instead of making the wiring more complicated.

The suggestions given above, however, will not prevent some from attaching a piece of copper wire in place of the fuse ribbon, and those in charge should make periodical visits to each motor to see that the proper sized fuses are in use and that extras are kept on hand. If the sizes of fuses given will not carry the load the motor is either developing trouble, is already in trouble, or is too small for the load required. In this event a larger sized motor should be used.

Frame for Repair of Steel Tapes

Breaks in steel tapes are unfortunate but inevitable, and it is important that a surveyor be able to repair them accurately. The accompanying illustration shows a contrivance which may be used to hold the two ends of a broken tape while a sleeve is being soldered on the break. The device is rectangular in shape, and is made of $\frac{3}{8}$ x $\frac{1}{2}$-in. iron. Longitudinally across each

DEVICE HOLDS ENDS OF TAPE WHILE SLEEVE IS BEING SOLDERED ON

end a hacksaw cut is made $\frac{1}{2}$ in. deep, and near each end a $\frac{3}{16}$-in. hole is drilled one-half way through the frame, and tapped to receive a thumbscrew. The two ends of the broken tape are passed through the saw cuts in the ends of the frame, the ends being brought exactly together, and then the thumbscrews are set down tight. The surveyor can then proceed to clamp and solder a sleeve over the broken parts. The frame illustrated was made by E. B. Mills, surveyor for the Mason Valley Mines Co., Mason, Nevada.—*Engineering and Mining Journal.*

How a Western Coal Company Solved Its Labor Problem

By George C. McFarlane
Denver, Colo.

The coal industry is now passing through a depression that will strain the resources of many operating concerns. Of course, everyone felt that the erratic war-time prosperity would end some time, but scarcely anyone expected a slump in the middle of the present season.

Practically every mine in the country is in first-class shape physically, as all operators prepared for a tremendous rush of business which, however, did not materialize. Now, in the transition period between war and peace, is a good time to make a concerted effort to stabilize our industry.

The war has shown that public sentiment is the real ruling power, not only in this but in all countries. There is nothing to be gained by disguising the fact that the coal industry is in distinct public disfavor in the United States. The legislatures of the different coal states are continually passing harassing laws, and they are upheld by the public. In all wage controversies the demands of the coal miners are backed by the press of the nation. The coal industry as a whole must win the confidence of the public, and the operators must establish friendlier relations with their own employees, as other great industries are endeavoring to do. While some coal miners appear to be misanthropes, the majority of our mine workers possess great natural intelligence. As a rule, they dislike to be patronized, and much of the elaborate welfare work instituted by large coal operators is unappreciated. What the miner wants most is a chance to earn big money, and he will cross the continent to make a little larger wage.

Much of the bickering over wages which has periodically disturbed the public mind is caused by the semi-idleness of a large percentage of our coal miners. Coal mining is subject to seasonal and other factors that produce wide fluctuations in the volume of business throughout the year, and I believe it should be the aim of the operators and mine workers to gradually reduce the number of men who follow coal mining as a permanent vocation and increase the number of farmers, farm laborers, etc., who follow it as a seasonal occupation. If the surplus mine workers could be diverted to other lines of work, coal miners could be given practically continuous employment.

During the war period, with its insistent threat of a labor shortage, my company's mines were operated on the following basis, and despite the fact that our force was cut 40 per cent., we maintained our normal daily output:

We decided it would be better to concentrate our working force in five or six panels of a mine, and therefore we sealed off unused and worked-out parts of the mine with concrete stoppings. Our coal readily absorbs oxygen, and after an air current passes through a mile or two of workings miners cannot load as much coal on the return as on the intake. The timber in the return airways and in the upcast shafts decays rapidly, owing to fungus growths which thrive in air deficient in oxygen. Shortening the air travel caused such a marked inprovement in the return air that in a few weeks the fungus which was destroying our timber nearly disappeared.

During the slack summer period, we kept our day hands busy grading the haulage roads and putting the track and switches in first-class shape. The roads used by the gathering mules were surfaced with burnt rock and made as smooth as a macadamized road. When the winter rush of business came, we put those diggers who could never get enough cars on runs where the grades were favorable, together with crack drivers and the fastest mules. On runs where the grade was adverse to the loads, slower mules were used and the places were given to diggers who did not care to hit up a fast pace. So far as possible, diggers of nearly equal ability were placed on a run. Normally they were given cars as fast as they could load them, and an average of 12 tons per man was easily maintained.

For years we followed the policy of encouraging the farmers of the neighborhood to take up coal mining as their winter occupation, and with the addition of these men to our force we were able to produce our quota by increasing the output of each miner instead of putting on an army of "floating diggers."

Recovery of Pyrite from Washery Refuse*

By E. A. Holbrook
Urbana, Ill.

SYNOPSIS — *The utilization of coal washery refuse is frequently a perplexing problem. This waste product, however, often contains pyrite in commercially recoverable quantities. An efficiency of recovery of about 70 per cent. can often be realized by the installation and operation of comparatively simple and inexpensive crushing, screening, jigging and sometimes tabling apparatus.*

CAN coal washery refuse be utilized commercially? This question has occurred to every official connected with any coal company operating a washery. The great refuse heaps accumulating near every plant are not only a source of increasing expense because of their ever increasing size, but the fact that they are frequently on fire makes them disagreeable and sometimes dangerous.

Washery refuse is a mixture of pieces of shale, bony coal, and generally iron pyrites or "sulphur." Often

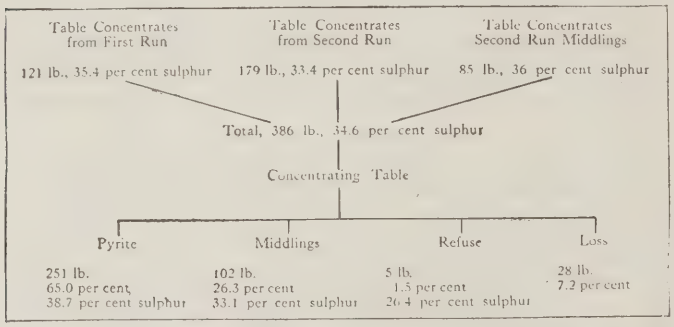

FIG. 1. FLOW SHEET—RERUN OF TABLE CONCENTRATES

some good coal is present. It is the iron pyrite content that offers commercial possibilities through its removal from the refuse, after which the remainder of the dump material can be discharged again in a size and shape that makes its handling easier and its storage safer. The market for iron pyrite is represented by the sulphuric acid plants, situated mostly east of the Mississippi River. The pyrite is the raw material which is burned or roasted for the production of sulphur dioxide, which in turn is converted into sulphuric acid. Pyrite thus becomes a necessary material for the manufacture of explosives and other so-called essentials in war times, as well as fertilizers.

It is impossible to tell by the eye or even by handling how much pyrite is contained in any washery refuse. In general, pyrite when prepared as a separate product for the market should contain a minimum of 40 per cent. sulphur. When absolutely pure pyrite contains about 53.4 per cent. sulphur and 46.6 per cent. of iron. The pyrite lumps found in washery refuse, when cleaned of adhering coal or shale, analyze as high as 48 per cent. sulphur. When it is considered that imported Spanish pyrite only analyzes from 46 to 48 per cent. sulphur, the purity of this material obtained from the best washery refuse pyrite is apparent.

It is true that much of the washery pyrite is dull grey or black in color and often has a stony amorphous structure, while the ordinary pyrite is bright, brassy yellow and shows an attractive crystalline formation. Nevertheless much of the washery product is high grade in sulphur, and the dull color often comes from a minute percentage of impurity, such as carbon, acting as a coloring material.

During the war, as a shortage of pyrite was threatened, the Bureau of Mines in coöperation with different state organizations conducted a survey of the different coal fields to learn their pyrite-producing possibilities. This work included a survey of coal mines and material dumped as refuse from many washeries. The utilization of the pyrite on a large scale from the coal mines may not be a commercial venture under peace-time conditions, but the pyrite in washery refuse is in many cases probably profitable of recovery even in normal markets. The following factors must be considered:

1. How much pyrite is there in the washery refuse? Roughly this is arrived at by determining the sulphur content of the refuse material and multiplying by 2. For example, a refuse analyzing 12 per cent. sulphur would have about 25 per cent. pyrite present. At many washeries the refuse examined contained so little pyrite as to be worthless; for example, one refuse analyzed only

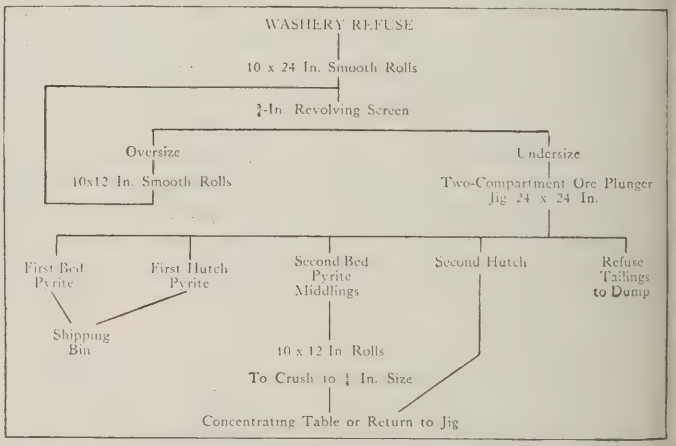

FIG. 2. FLOW SHEET—WASHERY PYRITE RECOVERY PLANT

4 per cent. sulphur or 8 per cent. pyrite. On the other hand, one refuse examined contained 25 per cent. sulphur or 50 per cent. of pyrite. These were the extreme cases. As the pyrite is about three times as heavy as the rest of the refuse, a small mass of it makes an astonishingly large proportion by weight.

2. In what condition is the pyrite? A small amount of the sulphur in the refuse may be combined organically and not be in the pyrite form. In some cases the pyrite is present mostly as small, bright, shiny scales, looking almost like colored fish scales. This form of pyrite is light in weight and generally of low sulphur

*Published by permission of the director of the United States Bureau of Mines.

content, in spite of its glistening appearance. Unless the refuse contains a large proportion of the pyrite in a lumpy, stony, hard form of a size equal to the rest of the refuse, its recovery probably is not inviting commercially.

3. What is the purity of the pyrite itself? Attention has been called to the varying purity of different samples. Chemical analysis for sulphur is the only reliable indication. In some cases the apparently pure pyrite was found to contain so much carbonate of lime or iron as to be below commercial grade, even as a cleaned product.

If the foregoing three factors are favorable in a washery refuse, attention should be given to its possible commercial recovery because such recovery involves only the addition to the existing washery of a crushing plant and a suitable jig. It also means easier disposal of the crushed refuse after the pyrite is extracted, as this fine material may be pumped or sluiced easily to the dump.

laboratory on washery refuse from Pennsylvania, and brings out the peculiarities of the pyrite in washery refuse and indicates that a simple plant would make a satisfactory saving. The plant already in operation makes a slightly higher grade of pyrite than was indicated by similar preliminary tests.

Report on Tests of Washery Refuse

Early in September, 1918, at the laboratory of the U. S. Bureau of Mines at the University of Illinois, about a ton of washery refuse was received from the Cascade Coal and Coke Co., Tyler, Penn. As this material contained pyrite, or "sulphur," it was desired to learn if this pyrite could be mechanically extracted from the refuse on a commercial basis. Tests of crushing, jigging and tabling the material were made as follows:

The material consisted of a mixture of pieces of pyrite, shale and bony coal of all sizes up to about 2 in. in greatest dimension. Many of the larger pieces

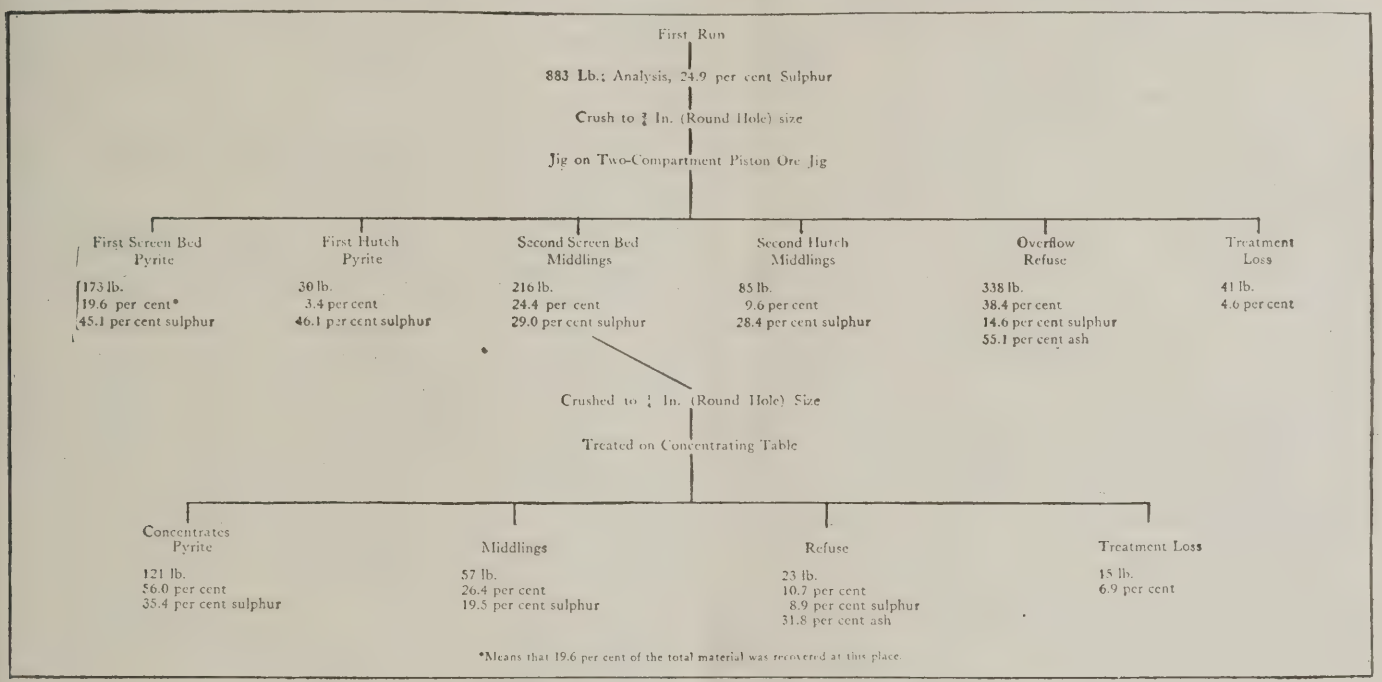

FIG. 3. FLOW SHEET OF FINAL TEST RUN OF WASHERY REFUSE

Furthermore, this reduces the danger of fires in the refuse pile.

The value of the recovered pyrite varies according to its purity and to market conditions, but an index is that the quoted price of Spanish pyrite at the Atlantic seaboard before the war was about $5 per ton. It should be remembered that pyrite treatment at a washery involves no cost for raw materials and only an operating expense and an interest charge for the plant. Moreover, it provides a use for a present worthless product.

Within the past year at least one large coal washery in the United States has installed a pyrite-saving plant, and this is reported to be running successfully. The preliminary tests on this plant and on material from several other washeries have been carried out by the Bureau of Mines in the coal-washing laboratory of the Mining Department of the University of Illinois, Urbana, Ill. No specific rules can be laid down to govern every plant, but individual experiments are necessary in every case in order to secure satisfactory results. The following report details the tests made at the

were a mixture of shale and pyrite. Graded crushing was tried, and samples were crushed to various sizes and examined to learn if the larger pyrite pieces were free from shale. In this way it was determined that crushing all the material to a maximum size of ¾ in. (round hole) would unlock a large percentage of clean pyrite. Consequently this size was chosen as the proper one before treatment.

In crushing, the pyrite showed but slight tendency to crumble and break into fine sizes. This is important because it simplifies the treatment. If, on crushing, the valuable mineral tends to crumble, it makes necessary an expensive treatment of fine material. In this test the pyrite seems stony and the fine sizes contain less pyrite than the coarse.

In testing material of this character it is possibre by fine crushing and complicated treatment to recover nearly all the pyrite. Commercially, on account of the moderate value of the product, it is better to simplify the treatment, at the expense of losing a little pyrite. Consequently after the preliminary tests, plans were

outlined for two final tests on the material as follows:

The first provided that after crushing to ¾-in. size the whole material should be treated on a two-compartment jig with the hope of recovering the coarse pyrite on the jig beds, and of saving the fine pyrite as hutch products in the bottom of the machine.

The second contemplated that after crushing the material to ¾ in. it be rescreened on a ¼-in. screen, and the material between ¼- and ¾-in. size be treated on a jig and the material under ¼ in. in size on a concentrating table. After crushing to ¾ in. the material was treated on a jig according to the first plan mentioned.

The accompanying flow sheet (Fig. 1), called the "Flow Sheet of First Test Run," outlines the work done and the results. The material jigged weighed 883 lb.

RESUME S HEET—FIRST RUN—WASHERY REFUSE FROM CASCADE COAL AND COKE CO., TYLER, PENN.

Original weight, 883 lb.; analysis, 24.9 per cent. sulphur

Product	Pyrite—Weight, Lb.	Pyrite—Sulphur Analysis, Per Cent.	Middlings—Weight, Lb.	Middlings—Sulphur Analysis, Per Cent.	Tailings—Weight, Lb.	Tailings—Analysis, Per Cent.	Loss
First bed pyrite	173	45.1	....	....	.....	.....	...
First hutch pyrite	30	46.1	....	....	.....	.....	...
Second bed middlings			See Table Products				
Second hutch middlings	....	....	85	28.4	.....	.....	...
Jig refuse	....	....	....	....	338	14.6 sulphur 55.1 ash	...
Table pyrite	121	35.4	....	....	.....	.....	...
Table middlings	....	....	57	19.5	.....	.....	...
Table refuse	....	....	....	....	23	8.9 sulphur 31.8 ash	...
Jig loss	....	....	....	....	.....	.....	41
Table loss	....	....	....	....	.....	.....	15
Totals	324	41.6	142	24.9	361	14.2 sulphur 53.6 ash	56
Percentages	36.6	....	16.1	....	40.9	.....	6.4

From 883 lb. of washery refuse, 324 lb. of pyrite were recovered or 36.6 per cent. by weight. This analyzed an average of 41.6 per cent. sulphur.

The middlings product of 142 lb., or 16.1 per cent., analyzed 24.9 per cent. sulphur. If commercially profitable, this middlings could be treated for the recovery of part of its contained pyrite.

The refuse tailings, 40.9 per cent. of the material by weight, contained 14.2 per cent. sulphur and 53.6 per cent. ash.

Expressed in another way, from 219.9 lb. of sulphur in the original refuse there was recovered 134.8 lb., or 61.3 per cent.

and contained 24.9 per cent. of sulphur, or roughly 49 per cent. of pyrite by weight. Clean, coarse pyrite was recovered from the first screen bed, and clean fine pyrite was recovered from the first hutch. The second screen bed gave a middlings product, or one composed of pieces still containing a mixture of shale and pyrite, which must be crushed finer before unlocking the pyrite. The flow sheet shows these middlings were recrushed to ¼-in. size and treated on a concentrating table with fair results. The overflow refuse was a shale low in pyrite and a bony shale.

The résumé sheet of the first run lists all the products obtained and shows the recovery of pyrite to be 36.6 per cent. by weight of all the material treated. Expressed as sulphur, 61.3 per cent. of all the sulphur was recovered as pyrite by two simple operations—jigging, followed by tabling the recrushed middlings. In a small plant the table could be eliminated and the recrushed middlings fed back to the jig.

The fine pyrite recovered from the table is of lower grade than the coarse pyrite recovered on the jig, the respective amounts of sulphur being 35.4 per cent. and 45.1 per cent. This was contrary to the results obtained on most pyrite which has been tested in the laboratory. The reasons for this will be discussed later. However, since 40 per cent. sulphur in pyrite may be taken as the minimum desirable percentage, if the lower grade pyrite from the table is mixed with the high grade pyrite from the jigs, the mixture has a grade of 41.6 per cent. sulphur, which is satisfactory.

In the second test, after crushing to ¾ in. the material was passed over a ¼-in. screen and the ¼- to ¾-in. size was treated on a jig, while the size smaller than ¼ in. was treated directly on a concentrating table, according to the second plan previously mentioned. The flow sheet of this second test is shown herewith (see Fig. 3) as is also the resumé sheet.

Comparison of the Two Tests

The two tests just described were run under the same conditions. The first was the more simple method and gave the purest pyrite. However, the second method gave a recovery of 72.4 per cent. of the total sulphur as against 61.3 per cent. by the first method.

In both tests the pyrite recovered on the concentrating table contained less than 40 per cent. of sulphur. This was probably caused by the fact that there is a small amount of carbonate of iron in the fine material, and this stays with the pyrite and cannot be removed by concentration.

To test whether or not these fine table concentrates could be improved by further treatment, all the table concentrates from all the runs were united and again

RESUME SHEET—SECOND RUN—WASHERY REFUSE FROM CASCADE COAL AND COKE CO., TYLER, PENN.

Original weight, 878 lb.; analysis,; 24.9 per cent. sulphur

Product	Pyrite—Weight, Lb.	Pyrite—Sulphur Analysis, Per Cent.	Middlings—Weight, Lb.	Middlings—Sulphur Analysis, Per Cent.	Refuse—Weight, Lb.	Tailings—Analysis, Per Cent.	Loss

Percentages	48.9	....	...	19.9	24.1	.....	7.1

From 878 lb. of washery refuse, 429 lb. of pyrite were recovered, or 48.9 per cent. by weight. This analyzed an average of 36.9 per cent. sulphur.

The middlings product of 142 lb., or 16.1 per cent., analyzed 17.3 per cent. sulphur. If commercially profitable, this middlings could be treated for the recovery of part of its contained pyrite.

The refuse tailings, 24.1 per cent. of the material by weight, contained 12 per cent. of sulphur and 44 per cent. ash.

Expressed in another way, from 218.6 lb. of sulphur in the original refuse, there was recovered 158.3 lb. or 72.4 per cent.

concentrated. The result is shown in the flow sheet called the "Rerun of the Table Concentrates."

The second run shows that it is not commercially possible to greatly improve the grade of the fine pyrite from this washery.

Conclusions

The washery refuse from Tyler, Penn., is rich in pyrite. Practically and commercially about 70 per cent. of this material can be saved in the form of pyrite of a grade containing at least 40 per cent. of sulphur.

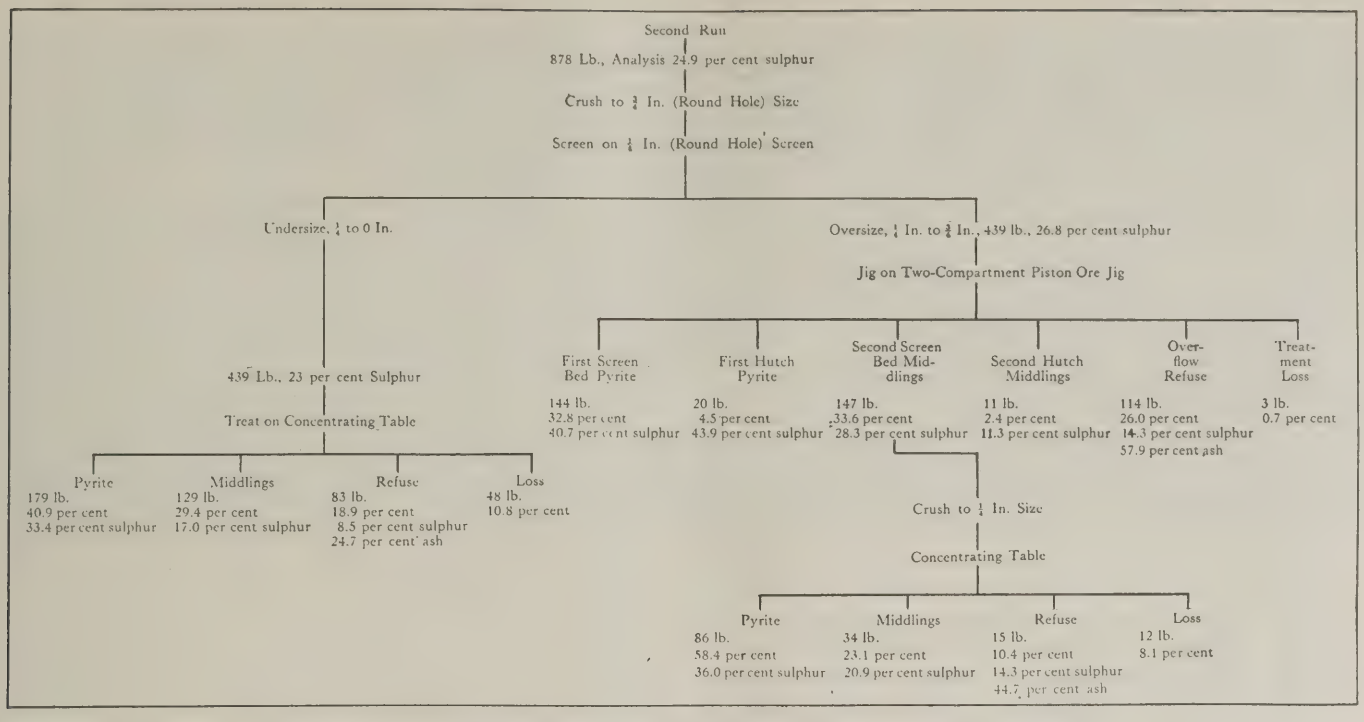

FIG. 4. FLOW SHEET OF SECOND TEST RUN OF WASHERY REFUSE

The refuse from this treatment is a bony shale, of about 13 per cent. sulphur existing in a very finely divided form, and it also contains about 50 per cent. ash. It is worthless as coal. Its high content shows that the coal washing carried out at the Cascade plant is efficient; that is, if the refuse as received at the laboratory at Urbana had contained much good coal, this would have accumulated at the jig overflow and revealed itself in a low ash analysis.

If the Cascade washery furnishes 30 or more tons of refuse per day, a simple pyrite treatment plant should be built to handle the refuse. This should produce, from 30 tons of refuse, at least 12 tons of pyrite containing 40 per cent. of sulphur. A flow sheet of the proposed plant is shown in Fig. 2.

If more capacity is needed, a concentrating table to handle the second bed pyrite middlings after recrushing is recommended. The machinery needed consists of three sets of smooth rolls, one revolving screen, one 2- to 4-compartment ore jig and a shipping bin. Of course water pumps and power are necessary. The cost of machinery and installation should not exceed $8000 to $10,000.

An Episode in the Recent History of the Coal Mines of France

An interesting bit of history is connected with the coal mines about the famous former French city of Lens. At present it is a heap of ruins. The German army of occupation established itself during the first year of the war in a line of trenches squarely across the coal basin of Valenciennes in the neighborhood of Lens, in the north of France. This position was held by the enemy throughout the greater part of the war, and the greatest destruction to the coal mines and surface plants is evident in this section. There were three zones in this coal basin during the war—one along the battle line and the others on either side of this territory. To better understand what followed the German invasion, it should be realized that about 90 per cent. of all the coal production of France was controlled by the Comité Central des Houilleres (Central Coal Operators' Association). The mines of this combination are all connected underground, and poisonous gases tended to circulate through the workings to the west of the battle zone from grenades and shells thrown down shafts by the Germans.

The French worked the mines in the territory west of Lens and it soon became necessary to build concrete dams in the mine entries and other openings both to keep the Germans out and preclude the possibility of their sending gas through onto the French miners. As the water rose in the workings to the east, these dams assumed an increasing importance as it was evident that the enemy aimed to stop French mining operations by every means in its power. The task of building these dams was attended with considerable risk. A Canadian officer was in charge, and he kept his men at work in the face of the many dangers surrounding them. Thus the workings were saved and in recognition of his notable achievement, the Canadian was awarded the war cross of honor. Pierce Williams, of the United States Consular Service, is the authority for this information, and he regrets his inability to state the name of the officer who so distinguished himself. As the Germans made good use of the opportunity to mine coal in the workings to the east of the line of trenches at Lens, it is thought that they also kept the mines in their territory from being flooded by a similar method.

To the east of the battle line the damage to the mines was less and less as the distance increased from Lens, until in Belgium the injury in the mine workings was negligible—there was little accumulation of water in the Belgium mines. However all removable metal and machinery was confiscated and sent to Germany.

The coal plants to the east of Lens in France and extending into Belgium were operated at all times by the Germans practically during the whole war—to the extent of their ability in obtaining men to work in the mines.

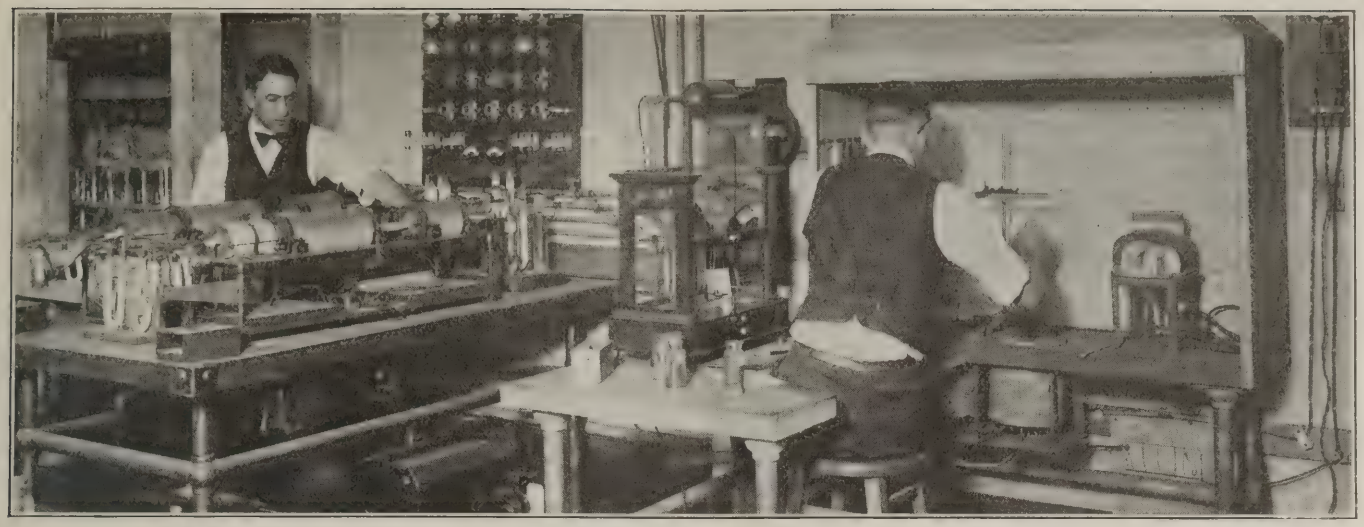
The New Pittsburgh Station of the Bureau of Mines—III

By George W. Harris
Editorial Staff, *Coal Age*

THE war greatly disorganized both the personnel and the work of the Bureau of Mines. During the last few years, however, much of value has been accomplished in the laboratories—of value at the time of need and for the future. In that period we progressed in conservation and standardization, and also in elimination of waste. The Bureau of Mines is especially interested in investigations looking to the increase of health, safety and efficiency in the mineral and metallurgical industries. But on the outbreak of war the work of the Bureau was concentrated on those problems whose solution would most increase national efficiency in war. This brought about many changes in the Bureau's organization. Many investigations were temporarily suspended and others were started and vigorously prosecuted.

The Pittsburgh station took a leading part in the work of the Bureau. The administrative affairs of this station were placed in the hands of D. A. Lyon, with the title of Supervisor of Stations, and with headquarters at Pittsburgh. He is the supervisor of all the field mining experiment stations.

The Pittsburgh station of the Bureau moved from its old location in the city arsenal into its new building on Forbes Street in October, 1917. At this time O. P. Hood, the chief mechanical engineer of the Bureau, was in charge, but owing to the necessity of his frequent absence from the plant W. R. Talbot was made acting superintendent. This arrangement was continued until Mr. Lyon arrived in Pittsburgh in September, 1918, as supervisor of all stations. At that time Mr. Talbot resumed his former duties as chief clerk, in charge of the personnel of clerical, purchasing, stockroom, filing, library and similar service. The work of moving the station into its new quarters was attended with difficulty and inconvenience, but it was managed so as to interrupt the work of the station as little as possible. The main part of the new building was available early in the fall of 1917, and at that time was occupied by the administrative offices and the various mining sections. Later the new chemical laboratories were occupied one by one, but the fuels section remained at the arsenal during the winter of 1917-18, as the power plant at the new site was not completed. A number of makeshifts were necessitated. Electric current was obtained from the city lines and steam from the nearby plant of the Carnegie Institute of Technology. H. A. Dent is now mechanical superintendent and has charge of the power plant, machinists, other mechanics and laborers. Special mention was made of the power plant in the first installment of this article, in the Apr. 17, 1919, issue of *Coal Age*.



The transference of the station's departments and equipment was conducted under most trying circumstances, and it was extremely inconvenient to carry on the work of the station under such adverse conditions. But the new quarters are a most welcome change from the accommodations of the old arsenal. Here was a chance to correct and improve on old practice and equipment, and full advantage was taken of this opportunity wherever practicable. Considerable time was given to the moving and to the instalment of chemical equipment in the new building. The supervising field chemist of these chemical research laboratories is A. C. Fieldner.

These laboratories occupy practically an entire wing of the station and the work done here is quite diversified. A large amount of routine and investigational work is done by the various divisions. For example, during the last fiscal year over 2000 samples of coal and miscellaneous materials were analyzed, involving 17,477 determinations. Another line of investigation was the determination of the fusing point of coal ash of the coals of a number of states. The results of fusing tests made on the ash of the coals of West Virginia were completed and published, an account of which was reprinted in the Jan. 2, 1919, issue of *Coal Age*, under the title "Fusibility of West Virginia Coal Ash." The results of similar investigations were published in the Apr. 17, 1919, issue of *Coal Age* under the title of "Fusibility of Ash from Coals Found in the Interior Province." The routine analysis and the investigation of mine and natural gases have progressed; also, physical

GROUP OF PITTSBURGH STATION SECTION CHIEFS

ANALYTICAL APPARATUS IN CHEMICAL LABORATORY USED IN ANALYSES OF COAL
Apparatus at the right is used in the determination of volatile matter; the apparatus at the left is used for the determination of carbon and hydrogen

apparatus and measuring instruments have been tested and calibrated. The work of the Bureau requires apparatus not usually found in laboratories.

All research work is apt to appeal to those interested in technical and scientific matters, but space does not permit an account here of the many activities at the Pittsburgh station. However, one such research stands out of peculiar interest to coal men. That is the work being done on the constitution of coal by Dr. Rheinhardt Thiessen, microscopist of the station. A bulletin entitled "Structure in Palæozoic Bituminous Coals," by Dr. R. Thiessen, in press, gives the results of the author's work on the subject during the last ten years. It will be copiously illustrated by photographs of microscopic vertical and horizontal sections of coal. A free translation of the title of this bulletin might be "the origin, composition and general nature of coal"; its woody structure was thoroughly investigated and minutely analyzed. In addition to establishing the theory of the vegetable origin of coal, Dr. Thiessen also presents his evidence as to an index by means of which he correlates the different coal seams.

The chief coal-mining engineer of the Bureau of Mines—J. W. Paul—makes his headquarters at the Pittsburgh station. He has charge of all field investigations and all work at the Experimental Mine, near Bruceton, Penn., pertaining to coal mining. The mine safety engineer of the Bureau—D. J. Parker—also makes his headquarters at the Pittsburgh station. He has charge of mine-rescue operations, the testing of mine-rescue apparatus, the training of miners in first aid and rescue methods, and the conduct of rescue and first-aid contests.

A glance at Table I would leave little doubt as to why the principal field station of the Bureau is located at Pittsburgh. This city is practically the center of a district which includes about 57 per cent. of all the miners in the country. Neither is it strange that the Pittsburgh station is headquarters for those in charge of field investigations and mine rescue operations connected almost entirely with coal mining. The Pittsburgh, or North Appalachian mining, district registers nearly 67 per cent. of the coal miners of the whole country; the next important district—the Eastern Interior—includes only 19 per cent. of the whole number of coal miners in the United States.

The work of the mining section is done chiefly in the field, but it also includes special testing work in laboratories at experimental stations. Engineers are stationed at different coal centers and carry on investigations in mining practice and methods. They also cover safety features. Furthermore, attention is given to the conservation of coal with an idea of obtaining the largest percentage of yield. It is found that in some sections old methods are still used and that the recovery of coal is not what it should be. In such an event a study is made of conditions with an idea of offering

* Taken from Eighth Annual Report of Bureau of Mines for year ended June 30, 1918.

† Data as to miners of year 1914.

suggestions; possibly recommending a modification of practice to try to bring about a larger yield of coal.

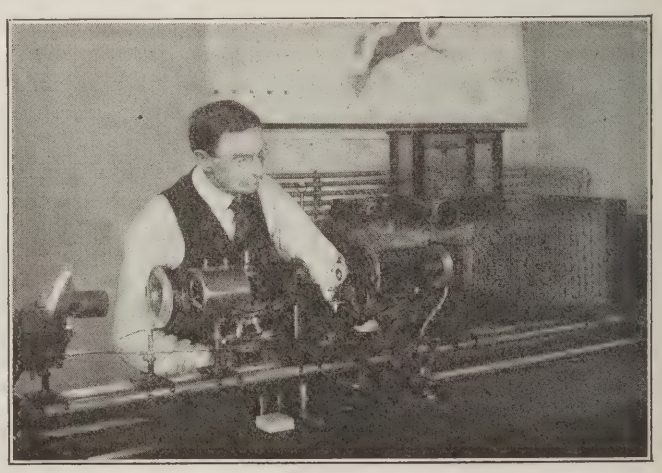
Special investigations are undertaken by the Bureau of Mines in the various coal fields of the country. However, it is distinctly understood that such work is not done for an individual but for a general class in a district. Then the particulars about such investigations are published and in this way all operators throughout the country receive the benefit of the Bureau's suggestions. In the case of an investigation of the circumstances attending mine explosions and of conditions in the mine after the accident, samples of coal, road and rib dust and of mine air are taken for analysis and examination. In some instances as much as five tons of coal are obtained. This is reduced to dust to approximate as nearly as possible the same dust conditions as existed in the mine at the time of the explosion. Then a test is made at the experimental mine near Bruceton, Penn., under Mr. Paul's direction. Here it is determined what amount of moisture and inert matter or rock dust are necessary to add to the coal dust to prevent a coal dust explosion; or what conditions

COAL CALORIMETER IN CHEMICAL LABORATORY
Apparatus is used in testing the heating value of coal

are necessary to limit an explosion. Finally the operator of the mine in question is furnished with a copy of the report of the whole matter, this report giving recommendations which will tend to prevent further explosions in the mine.

Foreign governments carried on certain investigations similar to the work of the United States Bureau of Mines at present, before this Bureau was in the field. England, France, Belgium, Germany and Austria all made investigations. These countries were visited by officials from the United States, in some cases more than once. The testing galleries were above ground and consisted of steel or wood tubes. We have reproduced their steel tubes here and have gone in advance of any of the foreign countries in the development of an actual coal mine in which to conduct experiments. In our experimental work we have had the benefit of the advice of foreign engineers engaged in experimental work. The result is that we have the most advanced coal mine experimental station in the world.

It is the policy of the more progressive coal companies to send their engineers to other fields to investigate mining methods and the handling and preparation of coal. Last year a delegation from one of the prominent Illinois coal fields visited the Pittsburgh station and the experimental mine. Since the return of these coal men, one of the largest of the Illinois companies has spent several thousand dollars in installing certain safety features in its mines. For example, at the experimental mine near Bruceton certain devices are used to control or limit explosions. The Illinois company adopted similar control devices. An account of the Bureau's investigations in regard to explosions can be found in the Aug. 11, 18 and 25, 1917, issues respectively of *Coal Age,* under the title of "Coal Mine Investigations." As a substitute for rock dust with which to combat explosions some of the western mines are using adobe. It his been analyzed and it is known to be well adapted for the purpose.



The action of mine explosions has received considerable attention from the officials of the Pittsburgh station mining section. They have learned just what happens and when it takes place. A sample of mine air has been taken before, at and after an explosion at the Experimental Mine for the purpose of investigation. It is also known if there was any vibration of air backward or forward during the explosion. The direction of the force of an explosion and the location of coked coal dust are matters of considerable interest.

The French engineers claim that the surest indication of the direction of an explosion is indicated by the location of coked coal dust, it always being on points opposite to the direction the explosion takes. For example, in passing props or corners of ribs, eddy currents are formed and coke deposits are found at points where there is a slowing up of the explosion; a strong current blows the coked dust away. The Pittsburgh station is still investigating this French theory. As the experimental mine develops and a greater opening is secured, it is hoped to learn something definite about it. Already from observations made in this country it has been found that where there is an accumulation of coked dust there is evidence of a slowing up of the explosion. This is shown in rooms at the point where the room widens out.

The Pittsburgh mining section has given much attention to mining methods, investigating plans followed, noting the percentage of coal recovered and advising as to better systems. In connection with the Bureau's efforts to secure greater efficiency in mining it should be stated that the various methods are being studied with reference to the effect on the surface. This is notably true in the case of Illinois, where the surface is valuable and numerous suits have been brought against the coal companies for damages. Some of the coal companies here are only getting out 50 per cent. of coal and say that they cannot do better under the present conditions. It is hoped that the investigations will result in real benefit to the operators and the owners of the surface alike.

Another important activity of the mining section is coal sampling. When the Bureau started in, it was found that there was no standard method for sampling coal. Therefore the Bureau was obliged to establish a standard method, and that method has not changed. A sufficiently large sample should be taken to have it representative of the seam. It also requires some judgment in excluding or including impurities. Impurities are not included in the sample when they are rejected in mining or in the preparation of the coal at the tipple. This requires a nice balance of conditions. A sample should show the average quality of coal a mine loads on cars or makes into coke.

If the coal on cars analyzes high in ash or sulphur, then there would be no use considering that coal for special purposes, unless it was found to be due to impurities which could be reduced in amount by more

DR. R. THIESSEN, MICROSCOPIST, TAKING A PHOTOMICROGRAPH OF A THIN COAL SECTION

careful mining or preparation. Sometimes the coal itself is high in ash or sulphur. Some think sampling is severe, but it often corrects bad practice of operators or miners. Samples of impurities themselves are taken in the mines for analysis to note the effect on a shipment should they be included in it.

If a miner is alive to the dangers of his occupation and understands how to meet them successfully the battle is half won. This is the attitude of the mine safety section of the Bureau of Mines, under the charge of D. J. Parker, mine safety engineer, with headquarters at the Pittsburgh station. The work of the mine safety section consists primarily in providing for the education of the miner with a view first of preventing mine accidents, second of enabling miners to take care of injuries, and third, attention to sanitation, both in the miner's home and underground. In other words, the work of the section is for the purpose of conserving the life and limb of the miner. In order to conduct the mine safety work to the best advantage, the mining regions of the country are grouped into eight districts. An indication of the territory included in these districts is given in Table I, which also shows the number of miners in each. The districts are planned with special reference to mine safety and rescue work, hence

PITTSBURGH STATION TRAINING GALLERY
Crew at work wearing Gibbs breathing apparatus.

they are grouped around the respective rescue stations and headquarters of the rescue or mine safety cars—the fixed and movable stations. Both classes of stations are scattered throughout the country. The movable stations include eight rescue cars and four auto trucks. Three of the cars are of steel and three more of similar construction are building. There are seven fixed stations.

The field work of those connected with the mine safety section, in the event of mine explosions, is well known. Thirty-eight mine accidents were investigated by the Bureau during the last fiscal year, and of these 30 were in coal mines. This is one of the most important functions of the Bureau and the primary influence in creating the department. Valuable assistance is also given in the inspection of rescue apparatus owned by the mining companies themselves. Advice is given when requested as to the conditions of such apparatus and also to repairs when necessary. It is quite essential that a warning be sounded as to defective apparatus and the need of having all apparatus tested regularly and often by those qualified to judge as to its condition.

In addition to giving aid at mine disasters, the Bureau trains miners in first-aid and mine-rescue work, and organizes field contests in first-aid and mine-rescue work. The success of the Bureau's efforts in this direction is attested to by the interest the miners take

CREW AT WORK IN TRAINING GALLERY

in such matters. The Bureau reports that during the last fiscal year 36,274 miners visited the rescue cars, stations and trucks; 33,629 attended lectures and safety demonstrations and 8851 were given training. A special service by the Bureau last year was the training of soldiers at military camps in rescue and safety work, and also in the use of breathing apparatus in atmospheres containing poisonous gases.

During the recent influenza epidemic which caused so many fatalities among miners and such serious interruption at times to the operation of coal mines, an unusual opportunity was afforded the car employees to be of service. The crews of several of the cars devoted much time to aiding the hard-pressed people and hospitals; in a number of instances the car supply of oxygen and oxygen inhalators was brought into good use where the use of oxygen was prescribed by the proper authorities. The surgeons detailed for service with the Bureau rescue cars were put on special duty by the United States Public Health Department with a view to abating the epidemic and relieving the sufferers. Their work with the Bureau cars is ordinarily to investigate sanitary conditions at localities visited, give lectures on the hygiene of the home and on mine sanitation and how to prevent the spread of communicable diseases.

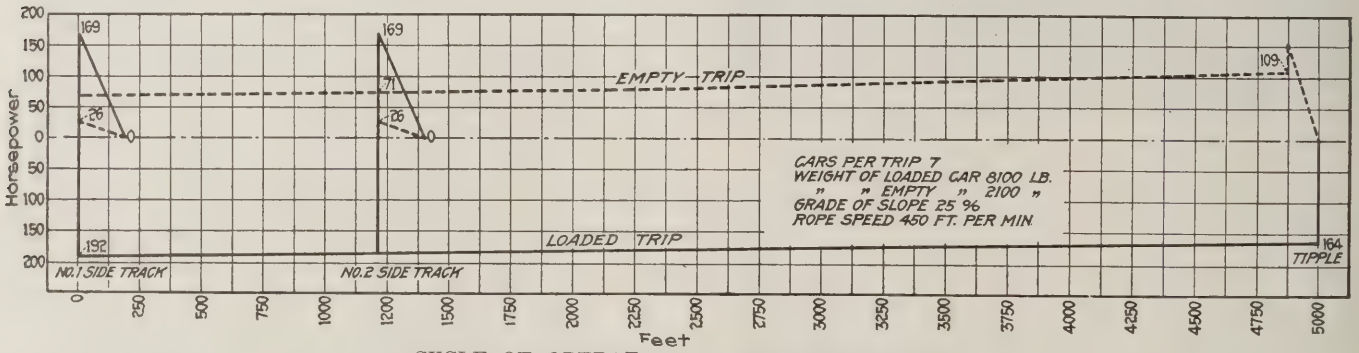
(To be concluded)

Comparison of Bituminous and Anthracite Statistics—1918

In the article "Comparison of Bituminous and Anthracite Statistics for Pennsylvania—1918," the output per inside worker in Pennsylvania in 1918 was compared with the output per employee in the United States in 1913. Obviously, the output per employee in the same area should have been taken in each case, the output in the bituminous mines in 1918 being 1009.87 per employee and in the anthracite mines 670.91. As in the bituminous mines of Pennsylvania, each man produced 1009 tons and the anthracite mines 520 tons the bituminous mines did not increase their output per man while the anthracite mines produced 29 per cent. more per head. Neither the bituminous nor the anthracite mines of Pennsylvania had in 1913 a general strike, so the comparison with 1918 would be closely comparable if only the bituminous region of Pennsylvania in 1918 had had an adequate car supply and the culm banks of the anthracite region been worked with equal assiduity in the two years mentioned.

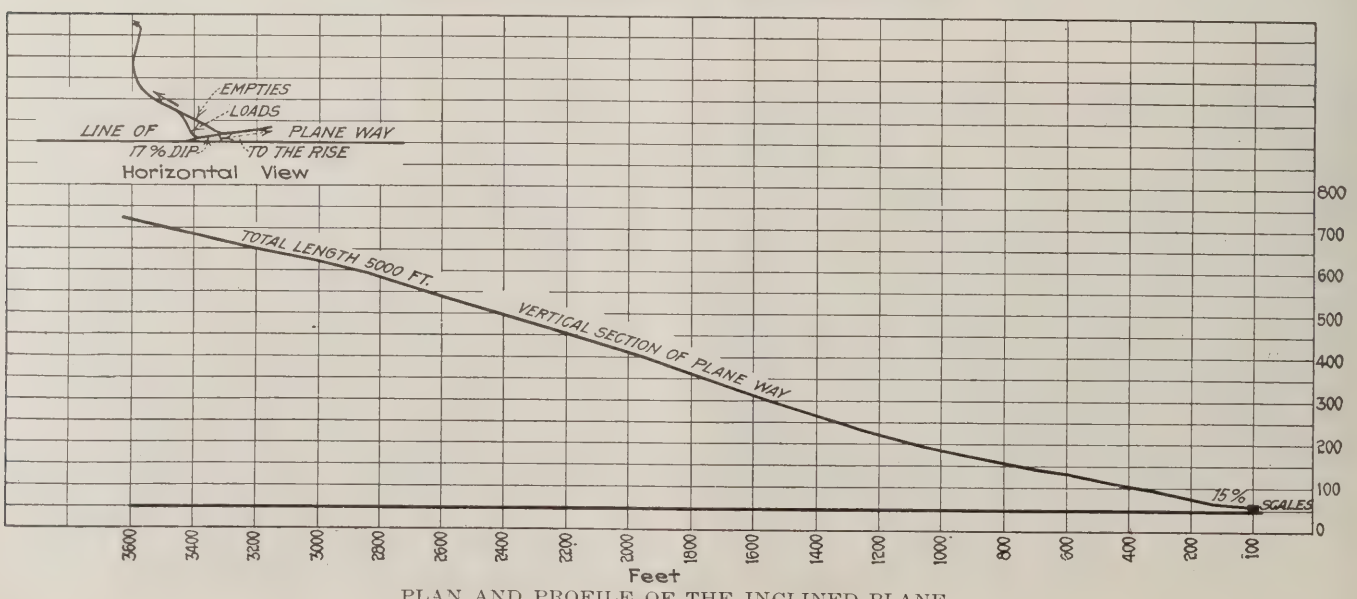
Inclined Plane of the Union Mining Co.

By U. U. Carr
Monongahela, Penn.



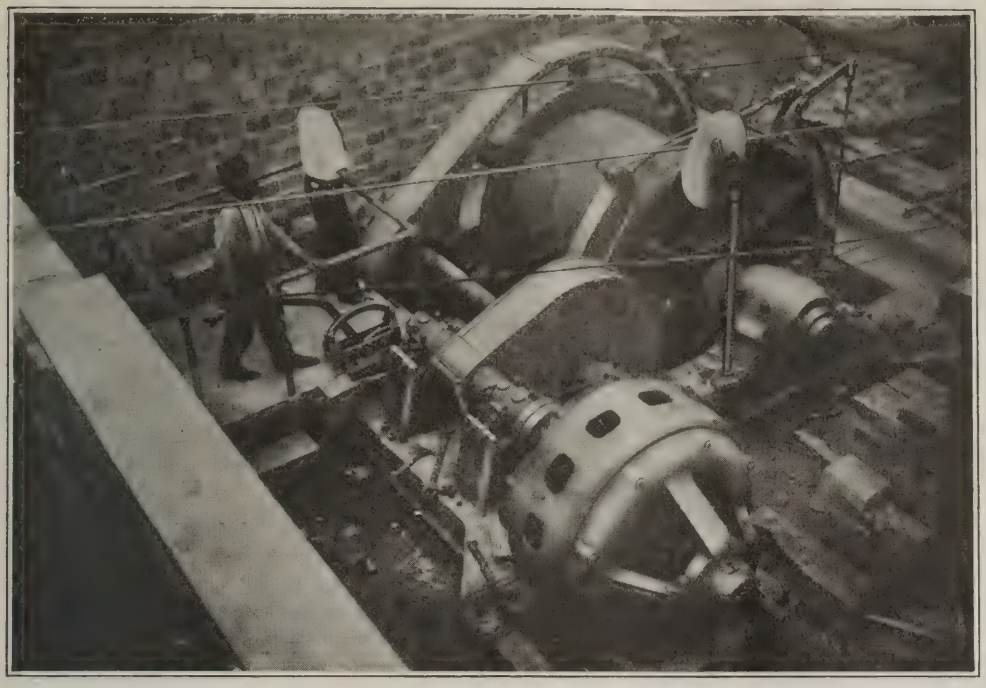
SYNOPSIS—*An inclined plane machine that had been used for several years proved inadequate to handle an increased output. Accordingly an electrically driven hoist was installed. This hoists empties and lowers loads. During the latter operation the motor acts as a generator and returns more power to the line than it consumes in hoisting.*

AN INTERESTING example in inclined plane operation is afforded by the electrically driven hoist recently installed for the Union Mining Co. at Mt. Savage, Md. This mining operation produces the fireclay used by the Mt. Savage Fire Brick Co. Two beds separated by 300 to 400 ft. of intervening strata are worked. The material is lowered down an incline 5000 ft. long having an average grade of 25 per cent. The usual type of incline machine had been operated for a number of years but proved inadequate to handle the present output. The installation of heavier machinery of a different type was therefore decided upon.



The hoist installed has a single keyed drum 60 in. in diameter with a capacity for coiling 6000 ft. of 1-in. rope. This machine is provided with post brakes and driven by a 200-hp. motor through two gear reductions. In operation trips of seven loaded cars, weighing 8100 lb. each, are placed on sidetracks at the different levels and adjacent to the single track of the incline. These trips are pulled from their respective sidetracks onto the incline, using the motor as a source of power. The motor is then reversed and, acting as a generator, furnishes the braking effect necessary to absorb the energy of the decending loads. The empty trip, also of seven cars, weighing 2100 lb. each, is pulled up the incline by the motor and lowered into the side track by means of the hand brake.

In lowering the loaded trip the regenerative action of the motor insures absolute safety from runaways, and a uniform speed is secured without effort on the part of the hoistman. The hand-operated post brake is of ample capacity to hold the load at any point. As an additional safeguard it is set by a weight and held in the released position by the operator, who is thus always ready to apply the brakes in case of failure of the power supply with a consequent loss of braking effect in the motor. It is to be noted that the hand brake is only used when lowering the empties onto the sidetracks. The disastrous heating and wearing of mechanical brakes incident to their use on long inclines is thus avoided.



The rope speed is 450 ft. per minute, and while no power readings are available the estimated power required to hoist the empty trip varies from 109 hp. at

CYCLE OF OPERATION OF THE MINE HOIST

PLAN AND PROFILE OF THE INCLINED PLANE

THE HOIST IN OPERATION BEFORE COMPLETION OF HOIST HOUSE

the bottom of the incline to 70 hp. at the top. In lowering, the loaded trip develops 192 hp. at the top of the incline, diminishing to 164 hp. at the bottom. The power developed is much in excess of that consumed and on a kilowatt-hour basis the power charge would be negative.

The hoist was designed and built especially for this service by the Diamond Machine Co., of Monongahela, Penn. It is driven by a Westinghouse Type C.W., three-phase, 60-cycle, 440-volt motor.

"Sengite"—A New Mine Explosive With a Guncotton Base

By M. Meredith
Liverpool, England

The manufacture of a new explosive, known as "sengite," to meet the shortage of nitroglycerine explosives, now used by the mining industry in South Africa, has recently been commenced in that country. The new explosive, which has a guncotton base, is the result of experiments conducted by Kynoch, Ltd., at the Umbogintwini (Natal) factory. It consists in the manufacture of tonite, in which nitrate of soda is substituted for nitrate of barium, which is usually used in that explosive. By this substitution it was found that an explosive of approximately similar strength to gelignite could be produced.

The process of manufacture is to incorporate the various ingredients, thoroughly clean, sieve and blend, and finally under hydraulic pressure press them into the shape of a cartridge. The pressure used is from 5 to 10 tons per square inch. In pressing a recess is left in the cartridge to receive the detonator. It is also possible by this process to leave a sufficient amount of water in the cartridges without appreciably reducing their blasting strength, with the advantage that the cartridge is a perfectly safe one to handle. This explosive is so insensitive to shock as to be quite safe if hammered with a steel tool. Accidental explosions in mining caused by drilling into unfired holes would not occur where this explosive is employed. Sengite, on the other hand, cannot be reliably detonated with an ordinary detonator, such as is used for tonite or gelignite. It will, however, detonate with absolute regularity if it is loaded and fired with a primer cartridge of gelignite or gelatine. The new explosive has been given a rigid test by a number of mines and has been found satisfactory in every way. The special equipment necessary, having a monthly capacity of 5000 cases, is now being built at Johannesburg. The sengite produced up to the present has been made on the original experimental machines. All of this has been of a uniform strength equivalent to ordinary gelignite.

Other derivatives have also been made, and it was found that a series of explosives containing other ingredients can be produced, so that weaker and cheaper forms of explosives can be made to take the place of the series of gelignites and dynamites, down to about the strength of 30 per cent. nitroglycerine explosives. The cost of producing sengite under war conditions was slightly greater than that of gelignite, but peace time prices may change this.

The name of this new explosive originated with the manufacturers, the first four letters being the initial letters of the following words "substitute explosive, no glycerine." The last three letters are taken from the word dynamite.

It is quite likely when an explosion occurs in a mine that the cage, signaling devices, headframe tower, or derrick may have been wrecked or disabled. Immediate preparations should be made to descend the shaft. To determine whether men are alive at the bottom, signals should be given by pounding on any pipes extending down shafts. Lack of response may be due to the pipes being broken. To make sure, get a ¼-in. rope, fasten to its end a lighted electric hand or flash lamp, a lighted safety lamp and a small cage containing a canary bird, and lower them to the bottom of each shaft. If men are alive at the bottom they may see the lights and give some signal or attach a message. The lower end of the rope should remain down five minutes, it should then be withdrawn, and the safety lamp and the canary examined. If the safety lamp is still lighted, and the canary alive or not disabled, men may safely descend the shaft, provided no change of ventilation in the meantime would cause the air in the shaft to change from still or intake to an upcase current. The return of the lighted safety lamp and the live canary will indicate that the oxygen content of the air is more than 17 per cent. (pure air contains about 21 per cent.) and that the carbon monoxide content, if any, is less than 0.20 per cent.—*Rescue and Recovery Operations in Mines.*

Coal Resources of Western Canada—II*

By James White
Assistant to Chairman, Deputy Head, Commission of Conservation, Ottawa, Canada

SYNOPSIS—*British Columbia, like Alberta, has coal in many stages of mineralization, but so large is Western Canada that the government believes it best to make plans for the carbonizing of the low-grade coals of Saskatchewan, thus saving freight and, incidentally, byproducts. The close of the article speculates on the possibility of such utilization of the Saskatchewan lignites and on the briquetting of near coke and the powdering of coal.*

THE Crowsnest region contains the most important body of coal now being mined in British Columbia. The coal covers an area of 230 square miles, and is a high-grade bituminous, occasionally running into anthracite, averaging about 64 per cent. fixed carbon. Much the greater portion of the coal is converted into coke, the remainder being sold as steam coal. There are 22 workable seams, with a total thickness of 216 ft., 100 ft. of which is estimated as workable.

In addition to the Crowsnest field referred to above, areas of coal-bearing rocks are found at several points in southern British Columbia. The Princeton field includes an area of about 50 square miles. At Princeton there is an 18½-ft. seam of lignite carrying 42 per cent. fixed carbon, 38 per cent. volatile matter and 16 per cent. moisture. At Nicola seams 6 ft., 10 ft., 5 ft. and 12 ft. thick respectively, have been mined. The Nicola coal is a sub-bituminous and analyzes about 47 per cent. fixed carbon, 39 per cent. volatile and 4 per cent. moisture. Coal has also been found at Tulameen, Kamloops, Hat Creek and North Thompson River. The total area in Vancouver Island underlain by coal seams is about 600 square miles. These coal fields contain some of the best steam coals on the Pacific Coast.

The coal of the Comox field is a coking, bituminous fuel and contains 57.2 per cent. of fixed carbon, the highest carbon content of all the Vancouver Island coals. Three seams have been mined in this field. The Nanaimo field has a productive area of 65 square miles, though the area underlain by coal seams is somewhat larger. The seams vary in thickness. Occasionally a seam containing from 2 to 3 ft. of dirty coal carries 30 ft. of clean coal at a point only 100 ft. distant. Run-of-mine coals from this field run as high as 56 per cent. fixed carbon and 43 per cent. volatile combustible; the commercial samples having a heat equivalent of 12,470 to 13,160 B.t.u.

The coal fields of the Queen Charlotte Islands are of Cretaceous and Tertiary age. The Cretaceous coals range from semi-anthracite to low-carbon bituminous. The Tertiary coals are lignites. In 1871 mines were opened in the semi-anthracite at Cowgitz, but the coal was so badly crushed that the enterprise was abandoned. This coal analyzed 83 per cent. fixed carbon and 5 per cent. volatile combustible; the fuel ratio being 16.5.

Central British Columbia has lignite beds at Alexandria, Quesnel and Prince George on the Fraser, on the Nazko River, Nechako River, Dean River and Lightning Creek. Three seams of bituminous coal, possibly a coking coal, aggregating 20 ft. in thickness, have been reported on a tributary of Morice River, and three seams on Goat River, a tributary of the Telkwa, aggregate 56 ft. in thickness.

The most important coals thus far discovered in the northern portion of British Columbia are the semi-anthracites and anthracites of the Groundhog Mountain area. An area of 170 square miles is assumed to be coal-bearing. It contains eight seams, with an aggregate thickness of 30 ft.

The "actual" and "probable" reserves in British Columbia are: Semi-anthracite, 1.9 per cent.; bituminous, 85.4 per cent.; low-carbon bituminous, 3.3 per cent.; cannel, 2.4 per cent.; lignitic, 7.0 per cent. Lignites have been discovered on Kispiox River, Sustut River, Peace River and Liard River. Bituminous coal has been found near Peace River cañon, and on the Taku River.

Canada's total consumption of coal in 1916 was 29,865,856 tons. Of this total, 41.3 per cent. was Canadian and 58.7 per cent. was imported coal. In normal times, taking the average during the period, 1894-1913, the consumption is about 48 per cent. Canadian and 52 per cent. imported, the increase in imports at the present time being due largely to the demands for munition and other manufactures in the coal-less portion of

TABLE VII. COAL PRODUCTION IN BRITISH COLUMBIA 1898-1917

Year	Tons	Value	Year	Tons	Value
1898	1,263,680	$3,384,858	1908	2,333,708	$7,292,838
1899	1,431,101	3,833,307	1909	2,606,127	8,144,147

*From a booklet entitled "Fuels of Western Canada." Continued from page 748 of the issue of Apr. 24.

Canada—Ontario and Quebec—and to the decrease in the production of Nova Scotia.

Locomotives, in 1916, consumed 8,677,354 tons. This constituted 29.1 per cent. of all coal consumed in Canada. It was 34.3 per cent. of the total consumption of bituminous and lignite in the Dominion and was 38.2 per cent. of the total consumption of bituminous.

The Vancouver Island and Nicola Valley collieries, in 1917, exported 32.6 per cent. of their output to the United States, exported 2.4 per cent. to other countries and sold 65 per cent. for consumption in Canada. The corresponding figures for 1912 are 21.2 per cent., 7.5 per cent. and 71.3 per cent. respectively. In 1902, 75 per cent. was exported to the United States. These figures show a remarkable change of market.

BRITISH COLUMBIA, SHOWING PRINCIPAL COAL-PRODUCING CENTERS

The production in the Crowsnest district in 1917 was 617,956 short tons. Of this production, 252,949 tons, or 40.9 per cent., was exported to the United States; 82,441 tons, or 13.3 per cent., was sold in Canada; 282,566 tons, or 45.7 per cent., was converted into coke or was used for colliery purposes.

In 1917, the Crowsnest Pass Coal Co. produced 504,762 short tons, the Canadian Collieries, 690,111 tons, and the Western Fuel Co., 714,533 tons, contributed, in the aggregate, 78.4 per cent. of the production of British Columbia.

In 1917, the Vancouver Island collieries produced 1,648,201 tons, or 67.7 per cent. of the output of the province; the Nicola-Princeton collieries, 167,731 tons, or 6.9 per cent.; Crowsnest (East Kootenay) district, 617,956 tons, or 25.4 per cent.

At present, owing to the war, abnormal conditions prevail, and anthracite is almost unobtainable west of Lake Superior. It has been predicted that when the war is over and conditions approximate to normal, hard coal will be marketed at a lower price. An examination of prices during the last 20 or 25 years, however, and the well-established fact that at the present rate of consumption the anthracite of the United States would be exhausted in less than a century, indicate that the theory of lower prices after the war is utterly fallacious. Even prior to the war, the production was decreasing at the rate of approximately 1 per cent. per annum. The question, therefore, is: What can be done in the way of producing a fuel that approximates to anthracite or toward the production and utilization of lignite under more advantageous conditions?

The briquetting of carbonized lignite promises to furnish an artificial anthracite. So far as the writer knows, however, no plant has yet produced it on a commercial scale, though, on the recommendation of the Research Council the Dominion Government has appropriated $200,000 for that purpose, this sum to be supplemented by votes of $100,000 each by Manitoba and Saskatchewan. In 1917, B. F. Haanel, of the Mines Branch, Department of Mines, investigated the process of manufacture and practicability, costs, etc., of the manufacture of carbonized lignite briquets. Presumably based on Mr. Haanel's report, the Research Council estimated that a plant with a capacity of 30,000 tons could produce the briquets for $7.25 per ton, assuming that the lignite, half slack and half run-of-mine required to produce one ton of briquets, could be purchased for $1.12½. As the production of slack in 1917, at the principal mines in the Estevan district, was only about 55,000 tons, it is obvious that all lignite required over and above this amount would be run-of-mine, which, on the basis of costs in 1917, increases the cost of the briquets 75c. per ton, or to $8 in all.

In 1917, the Commission of Conservation instructed its mining engineer, W. J. Dick, to make an investigation of markets, freight rates and cost and tonnage of lignite in the Estevan district. Mr. Dick reported that, based on the figure for operating expenses supplied by the Research Council, and allowing the manufacturer a profit of $1 per ton, the briquets could be marketed at a lower price than anthracite in western Manitoba and Saskatchewan, the price ranging from 45c. per ton less than anthracite in Portage la Prairie to about $2 per ton less in Moose Jaw. If run-of-mine coal is used, it will of course decrease this profit by 75c.,

but will leave an ample margin in the Regina and Moose Jaw markets.

In manufacturing carbonized lignite briquets, the raw material is heated in closed retorts to drive off the moisture and nearly all the volatile matter. The carbonized material is left behind as a coke which contains about double the amount of fixed carbon contained in the raw lignite. This carbonized material is mixed with a binder and compressed in a briquetting machine. Subsequently the briquets are waterproofed by heating, and so coking, the binder. Two tons of raw lignite produce one ton of briquets. This, of course, practically doubles the amount of fixed carbon and ash.

The question of the material to be used as a binder is an important one. Coal-tar pitch makes an excellent binder, but it is reported that the cost is high; the quantity available in Canada is also somewhat limited. Sulphite pitch, produced in the manufacture of paper pulp, has been successfully used as a binder in experimental work. The production of briquets of all kinds in the United States in 1916 was 295,155 net tons; in 1917 it was 406,856 tons; in 1916 the plant at Bankhead, Alta., produced 82,249 tons of briquets.

Pulverized coal was utilized first in cement plants and was found to be an excellent low-priced fuel of high efficiency. Later, it was applied in certain metallurgical processes and, during the last four years, several United States railways have successfully operated locomotives with this class of fuel.

In copper smelting, notable results have been achieved; furnaces, with a rated smelting capacity of 500 tons of ore per day, are now smelting twice that amount with pulverized coal. Notable economies have been obtained where it has replaced oil fuel, and a better distribution of heat has been obtained. W. G. Wilcox states that by comminution "we have changed entirely the characteristics of coal as commonly known." In addition to the greatly increased efficiency obtained, pulverized coal is practically smokeless, small coal can be utilized, anthracite culm, bituminous screenings and coke breeze assume a new importance, inferior grades of coal can be mixed with better grades and burned

‡Moisture and volatile combustible combined.

successfully, and the labor of the fireman is reduced to a minimum.

To obtain the best results, about 85 per cent. should pass a 200-mesh screen and it should contain not more than 1 per cent. of moisture. After being reduced to this high degree of fineness it is blown through a burner nozzle, the volatile gases of the pulverized coal igniting instantly. The fixed carbon is consumed by the heat of the volatiles, the flame resembling an oil or gas flame. By increasing or decreasing the supply of air or fuel, the operator regulates the supplies and has the operation under absolute control.

W. G. Wilcox, in the *Mining and Scientific Press*, June 22, 1918, p. 850, says: "By grinding an inch cube of coal so fine that 85 per cent. will pass a 200-mesh screen, we have increased the surface exposure from 6 sq.in. to approximately 1800 sq.in. Thus, we have increased the velocity of combustion 300-fold. By doing so, we have changed the characteristics of the fuel. We now have a fuel that is 300 times more active than the inch cube of coal, a new type of fuel that has in it inherent possibilities not to be found in lump or slack fuel."

Mr. Wilcox further points out that increasing surface exposure increases the intensity of the heat. The rate of combustion doubles for each rise of 18 deg. F., and thus pulverized fuel burns hundreds of times faster than lump coal.

In the manufacture of carbocoal, a high-volatile coal, after crushing, is distilled at a low temperature, 850 deg. F. to 900 deg. F. This first distillation yields gas and tar and a product, called "semi-carbocoal," which is high in carbon. The first distillation is continuous, the coal being agitated and mixed by a twin set of paddles. Thus all portions of the charge are uniformly distilled.

After mixing the semi-carbocoal with part of the pitch obtained from the tar produced in the first distillation, the mixture is briquetted. The briquets are then subjected to a second distillation at about 1800 deg. F., which yields carbocoal, additional tar and gas and a substantial amount of ammonium sulphate.

Carbocoal is dense, dustless, clean, uniform in size and quality, and stands transportation without disintegration; its density is greater than that of coke and more nearly approaches that of anthracite; the briquets can be made in any size from ½ oz. to 5 oz., the larger sizes being better suited for locomotives and the smaller being adapted for domestic use; the yield of tar and ammonium sulphate is also greater than is obtained in the byproduct coking process.

Where a coking coal is obtainable at a reasonable price, the establishment of central coking plants near large centers of population seems to offer the maximum of advantage. Such a plant would produce, a coke or artificial anthracite, gas for cooking or heating, coal tar which contains the elements entering into the manufacture of a whole series of valuable substances, benzol, toluol and other raw materials for explosives, aniline oil whence aniline dyes are manufactured, and ammonia, liquor from which is produced sulphate of ammonia, a valuable fertilizer. The coke thus produced can be used for all purposes for which anthracite is used. It requires a little more care in firing. Furnaces burning coke require a somewhat larger firebox than for hard coal.

W. J. Dick estimates that: "Such a plant established in the city of Toronto to supply 300,000 tons of artificial anthracite per annum would not only provide such fuel cheaper than anthracite, but would supply 1,500,000 M. cubic feet of gas at a cost of 10c. per M. at the plant; again, based on pre-war prices for cost of plant and bituminous coal, the profit on the undertaking would be considerably more than 50 per cent. per annum." Whether such coke plant be municipal or private owned, it offers what is, at the present time, the most promising solution of the fuel question for Saskatchewan, Manitoba, Ontario and Quebec.

The steadily increasing price of anthracite and the decrease in the reserves of this valuable fuel emphasize the warnings the Commission of Conservation has issued from time to time, urging the greater utilization of our water powers, both to decrease the consumption of imported coal and to use in bartering for such fuel in time of need. During the war, Canadians cannot expect to receive their full quota of anthracite, and the consumer should appreciate the necessity of using other coal fuel. The citizen who has, heretofore, burned anthracite regards the prospect of general use of raw bituminous coal with dismay, and will turn with relief to a smokeless fuel, such as coke, provided we can supply him with an article that has most, if not all, the characteristics of anthracite.

The initial difficulty in the preparation of such a fuel lies in the fact that Nature, with the agencies of pressure and time duration far beyond anything that man can hope to approximate to, has produced the dense, stony fuel which we call anthracite, whereas our

* Though not strictly germane to the subject of "Fuels of Western Canada," the analyses of typical and well-known coals of Nova Scotia and the United States have been added for purposes of comparison.

imitation—coke—has a cellular structure developed by escaping gas during distillation, a structure analogous to that produced in bread-making.

Hitherto, it has been assumed that coal should be coked practically at the pit mouth. The general acceptation of this idea is largely due to the fact that the coke was manufactured for metallurgical purposes, and the amount used by many smelters would not justify the erection of coke ovens at the smelter nor, in many instances, would it be possible to utilize all the gas produced in connection with the coking. On the other hand, a plant established near a large city has not only a market for the coke, or artificial anthracite, but also for all the gas produced.

Summing up the foregoing discussion of the economic utilization of our coals under existing circumstances, I am of the opinion that, speaking generally, coking plants established in the immediate vicinity of large markets offer the most advantageous method of utilizing coal for domestic purposes.

For large individual consumers, locomotives, and certain other uses, pulverized fuel promises to revolutionize present practice. It is almost axiomatic that the less labor and cost expended on the preparation of coal fuel the better; and, other things being equal, the process that approximates most closely to this dictum is the most efficient and most economic.

Owing to the slacking and crushing due to evaporation of the contained moisture, the mining of lignite is carried on in the autumn and winter, though the mines could be more efficiently operated in summer. To permit mining in summer, and to avoid slacking, it has been suggested that the lignite lump be put in pits in the ground and covered with earth, the covering being wetted from time to time if necessary.

Mr. Brereton, City Engineer of Winnipeg, states that good results have been attained by piling the lignite on the surface and covering it with slack. An application has been made for a patent on storing lignite lump in pits with masonry or concrete walls and bottom, but it is questionable whether this is a patentable device.

The Abuse and Care of Motors

By Richard Bowen
West Pittston, Penn.

With the passing of the mule comes a new era in the transportation system of every mine. In many mines where the development has reached to considerable proportions it is no small proposition to replace animal with mechanical power. Thousands of feet of trolley wire have to be strung, miles of rails have to be bonded and fishplated, and the switches and frogs that were in use oftentimes require replacement by heavier material. In order to do this we may have to take down roof, take up bottom, and in many cases do considerable skipping. This all goes on the deadwork list.

The foregoing is only a small part of the expense. There is the installation of the generator, motors, cables and everything that goes with the system if it is to be successful. It is during the installation of this material that great care should be taken by the person having charge of this work.

Particular attention should be given to the manner of hanging the trolley wire, as it has been my experience to find hangers work themselves loose two weeks after they were put in, resulting in the wire falling to the ground and coming in contact with the rail. Holes for the hangers should never be drilled where the roof is soft. It is far better to place pipe across from rib to rib and clamp the hangers thereto.

The position of the frogs and switches are also important. Of course, the position of the frog on the wire will be governed by the location of the frog in the road; hence it will be seen that all curves connected with the branches should have as long a radius as possible.

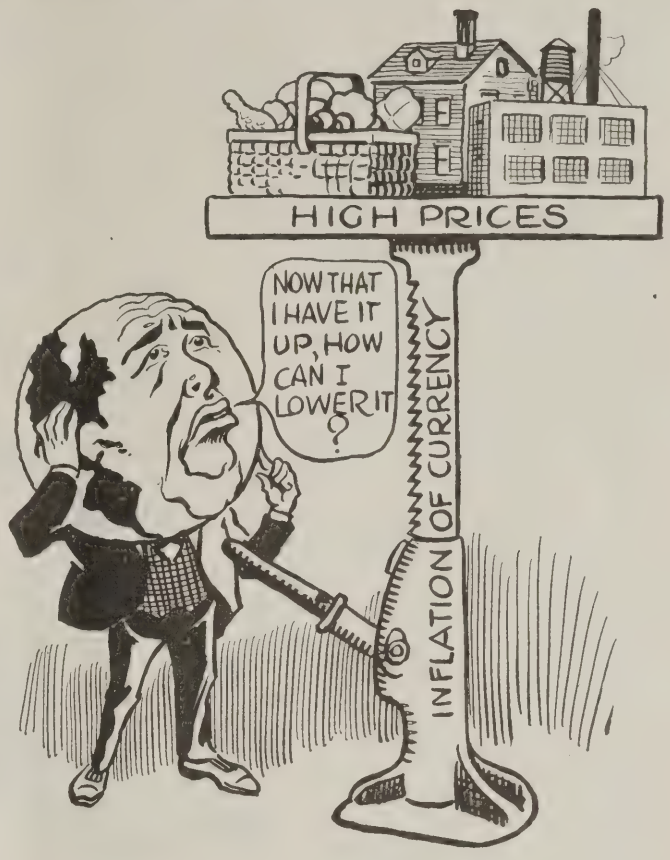
Every section of a mine where the haulage is done by electricity should have a circuit breaker of its own, so that if anything goes wrong with the power in one section it will not affect any other part of the mine.

All trolley wire at the foot of the shaft and along traveling roads and crossings should be guarded by strips of board 4 to 6 in. wide running parallel with the wire. The bonding of the road should be inspected every day and any defects remedied immediately. The power lost through defective bonding is sometimes greater than that required to start the trip.

In some mines mules and horses are badly abused; but this is as nothing compared with the abuse some locomotive runners give their machines. The durability and upkeep of a locomotive depend entirely on the care taken by the motorman. Two motors may work under identical conditions but be handled by different men. It will be found that it takes more to keep up one of them than the wages paid the motorman; and it is not unusual to change armatures on one motor two or three times as often as on the other.

The following are some of the causes that cost the company thousands of dollars yearly: (1) The motorman overloads his motor. This results in backing up the trip a dozen times in order to start it, even with a severe jerk. This wastes time and throws an undue stress on different parts of the machine. (2) Throwing the power on too quickly when starting the motor from rest. (3) Bringing the motor to a standstill when in full motion by applying reverse lever and brake. (4) Not shutting off power soon enough when about to couple the motor onto the trip. This results in a severe shock to the motor on coming in contact with the bumper of the leading car. (5) Not keeping sand boxes clean or oiling motor properly. Some motor runners use the same kind of lubricant for different parts of the machine. This should not be done. The fast-moving parts should have light thin oil while the journals and other heavier parts should have heavy oil or grease.

A good motor runner when starting his trip will throw on his power gradually as the load increases; and when he finds the load too heavy, he does not waste any time in jerking the trip but cuts it in two. He will always shut off the power before he applies the brake and never try to stop the machine by throwing the reverse lever unless there is danger of an accident.



He will also use his judgment when he is about to stop his motor for any reason. He does not wait until his trip is at the required spot and then throw his reverse lever and apply the brake in a hurry, but shuts off his power in time so that the trip will be near a standstill by the time it reaches the required point.

The ambitious motorman is always looking over his machine to see that none of the bolts, nuts or anything else has worked loose. If he finds anything of this nature he does not send for the head electrician but takes his wrench and tightens it himself.

Prices—Yesterday, Today and Tomorrow*

By O. P. Austin
Statistician of The National City Bank of New York

SYNOPSIS—*The author blames the increase in prices to inflation of currency, rather than to labor demands, and shows that it is world-wide and not restricted to belligerents or even to civilized people. It embraces all products at the place of manufacture, and so does not rest on war demands or transportation. Resting on inflation it will fall with deflation, but that deflation the author regards as extremely remote.*

In A few instances since the war there have been slight reductions in prices, but in others there are still advances, and the index figures on foodstuffs in New York today are actually higher than those on Nov. 5, 1918, when the whole world so joyously welcomed the apparent termination of the great conflict which had raged for 51 months.

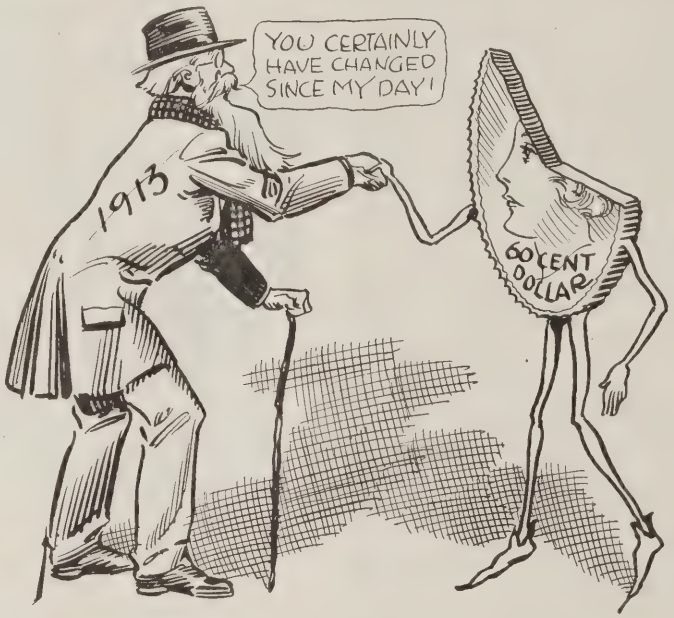
To attempt to determine what is likely to happen in the future we must try to find the cause of the things which have happened in the past, and also to see whether this cause is or is not likely to continue in the near future. When prices began to advance in the opening of war, we could readily see that the upward movement was due to the urgent demand for the food and raw material required by the enormous armies which had been put into the field, and this cause has been designated the "scarcity demand"; but when we found the advance extending to many articles in which there was no scarcity, and which were not used by the armies or utilized in the manufacture of their requirements, we began to realize that a part of the advance must be due to some cause other than mere war or scarcity demands.

Edgar Crammond, the distinguished British statistician and economist, in an address before the London Institute of Bankers on Mar. 26, 1919, stated that the three facts which would tend to make the fall in prices a very gradual one are: (1) The vast increase in the amount of paper money; (2) the huge increase in the amounts of public debts of the belligerents; (3) the determination of labor to maintain wages and improve the standard of living.

Raw silk, for example, for which the war made no special demand and which was produced on the side of the globe opposite that in which the hostilities were occurring, advanced from $3 per lb. in the country of production in 1913 to $4.50 per lb. in 1917, and over $6 per lb. in the closing months of the war. Manila hemp, also produced on the opposite side of the globe, and not a war requirement, advanced in the country of production from $180 per ton in 1915 to $437 per ton in 1918.

Mechanically ground wood pulp, not a war requirement, advanced from $14 per ton in the opening months of the war to $35 per ton in the opening months of 1916, and the grade known as "chemical bleached" advanced from $50 per ton at the beginning of the war to $100 per ton in January, 1919. Goat skins, from China, India, Mexico and South America advanced from 25c. per lb. in 1914 to over 50c. per lb. in 1918, and yet goat skins were in no sense a special requirement of the war.

Pig tin, produced by Chinese labor in the Malayan Peninsula and the Dutch East Indies, and not to a very great extent a war requirement, sold in the country of production in 1914 at 30c. per lb. and in the same markets at 75c. per lb. in the closing weeks of the war.



Sisal grass, produced in Yucatan, advanced from $100 per ton in 1914 at the place of production to nearly $400 per ton in 1918, and Egyptian cotton, a high-priced product, and thus not used for war purposes, jumped from 14c. per lb. in Egypt in 1914 to 35c. per lb. in 1918. Even the product of the diamond mines of South Africa advanced from 60 to 100 per cent. in price per karat when compared with prices existing in the opening months of the war.

The prices which I have quoted to you are in all cases those in the markets of the country in which the articles were produced, and in most cases at points on the globe far distant from that in which the war was being waged. They are the product of countries having a plentiful supply of cheap labor and upon which there has been no demand for men for service in the war. The advance in the prices quoted is in no sense due to the high cost of ocean transportation, since they are those demanded and obtained in the markets of the country of production.

Why is it that the product of the labor of women and children who care for silk worms in China and

*Paper presented at meeting of the Editorial Conference of the New York Business Publishers' Association, Hotel Astor, New York City, Apr. 11, 1919.

Japan, of the Filipino laborer who produces the Manila hemp, the Egyptian fellah who grows the high-grade cotton, the native workman in the diamond mines of South Africa, the Mexican peon in the sisal field of Yucatan, the Chinese coolie in the tin mines of Malaya, or the goatherd on the plains of China, India, Mexico or South America has doubled in price during the war period? The articles enumerated were in no case for use in the war, and the prices are those in the country of production and thus not due to the increase in ocean freights or dangers of oversea transportation. The advance has been general, world-wide. In a few articles in which an over-production was occurring, in which the demand fell below normal, the advance was not so strongly marked; but there is scarcely an article in the long list of those entering world markets in which there has not been an advance, no matter how distant its place of production from that in which the war was occurring or how little the war's demands for it or for the labor by which it was produced.

Surely there must have been some general underlying causes for this world advance, this simultaneous demand by people of all classes and in all parts of the globe for higher prices for their products irrespective of their relation to war requirements. While we may be willing to accept the immediate demands of the war as a partial explanation of the advance in the prices of foodstuffs and certain manufacturing material and manufactures, we must look further for the cause of the similar advance in articles upon which the demands of the war could have had no direct bearing. It is true that a marked advance in the price of one important class of products does cause an advance in the prices demanded for other articles which must be exchanged for those in which the advance has already occurred, but it does not seem probable that the advance due to scarcity of a comparatively few of the world products required for war could have been the chief cause of the doubling of prices in practically every article produced in every part of the world, many of which had not the most remote relation to war requirements.

Apparently the principal causes of the advance in prices during the war were, stated in their chronological order, first, "scarcity demand"; second, the advance in wages presumably due to the increased cost of living and demand for labor, and, third, the large increase in world circulating media, or, to put it in a single word, "inflation." Professor A. C. Miller, member of the Federal Reserve Board, an authority whose views are entitled to high consideration, in a recent address before the American Academy of Political and Social Science, named as the two chief causes of the advance in prices "scarcity demand" and "inflation," adding that "there is so much evidence of an artificial abundance of money in comparison with the things that are purchasable by it that the abundance of money must be credited with at least an equal influence in explaining the high prices which have prevailed."

What were the articles for which the war created a scarcity demand? Food, clothing, transportation facilities and material for the battlefield. How much did it add to the world's demand for these articles? Of course, the percentage of increase in demand for strictly war materials was very large, but was there really as great an increase in demand for other materials, food, clothing and transportation facilities as we are accustomed to imagine? Let us assume that the number of people participating in the war was forty million, which is probably more than those in the field at any one time. Do we realize how small a share those forty million were of the world's consuming population? Less than 2½ per cent. We think of forty million as a large number of people to feed, and so it is; but it must be remembered that the number of people in the world who must be fed and clothed and supplied with transportation facilities every day of the year is 1,800,000,000, or 45 times as many as the highest number in the military service at any time during the war. Of course, the soldiers were better fed than are many of the people in certain sections of the world, but even if their per capita consumption was four times as much as the average it would still represent but a small percentage of the world's daily food consumption. And it must be further remembered that all these 40 million people in the armies had been consumers of food before the beginning of the war, not to quite so great an extent perhaps as after entering the activities of the military service; but it cannot be assumed that the war added 40 millions to the world's consumers of food and clothing. Nor can it be properly assumed that the withdrawal of these millions from the industries actually reduced to that extent the world's producing power, for four millions of these were already in the military service and the places of the other 36 million were to a considerable degree filled by others who had not been up to that time actively engaged as producers.

Much of the material used in preparing the supplies for the battlefield was "switched" from the usual lines of industry, for there was an immediate cessation of railway construction, building operation and a thousand industries which formerly required manufacturing material; and as a result of this cessation of activities the material formerly used by them became available for war purposes.

It thus appears on close analysis that the scarcity demand created by the war was not so great in food, clothing or manufacturing materials as has been pictured, while the fact that 15 millions are still under arms minimizes the reduction in military demands which had been expected.

One factor often mentioned in the attempt to determine the causes of high prices is the advance in wages of labor, but the fact that the increase in compensation of labor was in most cases given because of the fact that the cost of living had already advanced at least somewhat minimizes the relative importance of this factor in attempting to discover the real causes of the general world-wide advance in prices. And it must also be remembered that several million persons who had not been engaged in the industrial and business world came to the assistance of those engaged in these duties during the war.

Where, then, shall we turn in the search for the principal cause of the general advance in prices of articles produced the world over and their relation to the demands of the war. What other cause can we find after giving due consideration to the scarcity demand, the destruction by war and the increased cost of labor? The most prominent among the possible or probable causes is the theory advanced or accepted by the historians, economists, statisticians and financiers of the world that inflation in currency is usually accompanied or closely followed by an advance in prices; and, as already indicated, so high an authority as a member of the present Federal Reserve Board, Professor A. C. Miller, has recently declared that "the abundance of money must be credited with at least an equal influence in explaining the high prices which have prevailed."

I wonder if we do fully realize the quantity of paper money which the responsible governments of the world have put afloat since the beginning of the war—thirty-six billion dollars. The paper money in existence in the 15 principal countries of the world at the beginning of the war was less than eight billion dollars, and at the end of the war was over 44 billions, an increase of 36 billions in 51 months, and this does not include any of the 80 billion dollars worth of paper currency issued by the Bolsheviki in the 18 months of their control in Russia. Thirty-six billion dollars of new paper money added to the circulation of the world by 15 responsible governments in a little over four years of time!

Advance in Prices Due to Paper Currency

We had been inclined to charge up the advance in prices occurring prior to the war to the fact that eight billion dollars worth of gold was turned out by the mines of the world in the 20 years following our famous gold and silver campaign of 1896. But here are 36 billion dollars worth of paper promises to pay turned out as legal tender money by 15 responsible governments in a short four-year period.

Do we realize how vast a sum is this 36 billion dollars worth of paper currency which has thus been put into circulation in such a brief time? It is more, in its face value, than all the gold and all the silver turned out by all the mines of all the world in the 427 years since the discovery of America.

True, much of this paper money is now more or less depreciated in its value as compared with gold, the world's accepted standard, but the fact that it has behind it not only a certain amount of the yellow metal but also the pledge of the governments by whose authority it was issued renders it at least an accepted medium of exchange in the countries of its origin, while the fact that nearly every neutral country of the world has meantime increased its paper currency and national indebtedness, permitting its gold to pass from circulation into the vaults of its banks as a security for the paper circulation, tends to widen the field affected by this inflated currency.

In addition to these vast sums of legal tender currency turned out by 15 responsible governments of the world, these same governments have at the same time made an even more spectacular advance in their issue of another series of promises to pay, which, while not legal tender in the ordinary sense of the term, do form a more slowly moving mass of currency. By this I mean the 180 billion dollars worth of bonds or other forms of national obligations issued by the governments of the world in the past four years, for national debts of the world have advanced from 40 billion dollars at the beginning of the war to 220 billions at its close. And while these bonds or other governmental promises to pay money at some future date are not legal tender currency in the ordinary sense of the term, they do pass current in the financial world and prove a basis upon which money may be readily obtained by their holders, and to this extent are an addition to the world's circulating medium.

Bank Deposits Show Enormous Growth

Still another increase in circulating media is found in the enormous growth in bank deposits, which of itself increases circulation through the increased use of checks, especially in countries such as the United States, where the check forms so large a share of the daily business transactions of the country. Bank deposits in 15 principal countries of the world have grown from 27 billion dollars in 1913 to approximately 75 billions at the present time, the ratio of increase being about the same as that of currency.

These increases, in circulation, indebtedness and bank deposits, while occurring chiefly in the countries participating in the war, have also extended to many other countries, especially in Europe, where the six principal neutrals have during the war period increased their national debts one billion dollars, their note circulation over a billion dollars and their bank deposits by about one billion.

Thus in a short 4½-year period world paper money has increased 36 billion dollars, world evidences of national indebtedness 180 billion dollars and world bank deposits nearly 50 billion dollars. Most of this enormous increase has occurred in "uncovered" paper. The gold mines of the world have turned out less than two billion dollars worth of the precious metal during the war period and most of the world's gold, which formed 55 per cent. of world circulation at the beginning of the war, has passed into the vaults of the governments of their great banks as a basis for their paper currency, and now bears a relation of but about 20 per cent. to the flood of paper money in circulation; and this proportion of gold to paper varies widely when the respective countries are compared.

If the world's historians, financiers, economists and statisticians are right in their general belief that an advance in prices usually accompanies or closely follows inflation in currency, and especially in paper currency, can we be surprised at the world-wide advance in prices which we have witnessed during the past four years, in which world currency and bank deposits trebled and national debts quintupled?

We come now to the third and final question, that of

prices of tomorrow. May we expect a material reduction in general prices in the near future? And in trying to determine this we must see whether the causes which brought about the advance during the war period are likely to be removed.

The chief causes of the advance seem to have been the scarcity demand, the higher cost of labor and the increase in circulating media.

The scarcity demand came on the very first day of the war, for most of the countries entering that struggle found that the demand upon them would be far in excess of their supplies either of foodstuffs or military requirements; and as the weeks and months and years progressed this fact was more strongly impressed upon them.

During the closing year of the war the ammunition factories of the various participating countries were able to meet to a great extent the requirements of their own armies, but in the matter of foodstuffs the scarcity demand still continues, with little prospect of abatement, at least in the near future. The number of mouths to feed in Europe has not decreased, and that continent, which has not for many years been able to produce its own requirements of foodstuffs, now finds itself with neglected soils, a disordered population and unable to return to normal production in the immediate future. In manufacturing materials, for which Europe has also been dependent upon other parts of the world, she will require abnormally large quantities at least in proportion to her attempts to manufacture, for her stocks of this class of merchandise are absolutely exhausted. In all parts of the world which have relied upon Europe and the United States for manufactures the shelves are empty and must be filled, and most of the manufacturing sections of Europe will evidently be slow in resuming the production of manufactures for exportation, and will have limited facilities for transporting or marketing them even if produced. So it seems that, although the demand for war material has terminated, the other features of the scarcity demand will continue, at least in a somewhat modified form in the immediate future, especially as relates to world requirements of food, manufacturing material and manufactures, while developments thus far do not point to an early reduction in labor costs.

If we are right in assuming that a considerable proportion of the world advance in prices is due to the enormous increase in world currency, can we expect a marked reduction in prices until the cause, inflation, is removed? Or, to put it in another form, that part of the advance caused by inflation can only be cured by deflation, by a reduction in the enormous stocks of currency which, as I have shown you, have trebled during the war, while that other form of slowly moving currency, governmental obligations, has quintupled.

Is it probable that these two forms of currency can be or at least will be reduced in the near future? The governments of the world, which were paying less than two billion dollars a year of interest on national debts at the beginning of the war, are now paying and must continue to pay a total of over 10 billion dollars a year in interest, and at the same time all other expenses of governments have advanced. Official estimates of the budgets or expense accounts of several of the principal countries for the coming fiscal year have already been announced and indicate that their necessary expenses in the first full year of after-war peace will be about four times as great as in the year preceding the war. The British budget for the next fiscal year is estimated at about six times as much as in 1913, and those of France, United States and Canada about four times as much as before the war. Present indications are that the governments of the world will be compelled to collect in taxes from their people about 50 billion dollars a year as against about 12½ billions in 1913, or say a billion dollars a week as against a billion dollars a month before the war; and this does not include anything for sinking funds or other provision for reduction of outstanding debts. If this be true, is it probable that the governments in those countries which have greatly increased their circulation and must now demand such enormous increases in annual payment of taxes will find it advisable or possible to materially reduce the amounts of currency available for such payments?

If the governments which have been the chief participants in the world increase of currency should fail to materially reduce that excessive supply, and if the world's demand for food, manufacturing material and manufactures is to continue at the present rate, are we justified in expecting a general reduction in prices in the near future? The question, I think, answers itself. There will, of course, be instances in which there will be material reductions, but in general terms the outlook for marked or rapid decline, at least in the near future, does not seem so very encouraging.

While there may be a downward trend in the general price level and distinct reductions in certain articles, the difficulty in removing the chief causes of the advance suggests that the general reduction in prices in the near future may not be as rapid as some people have anticipated.

Mining Congress Tackles Export Problem

A meeting of the coal-export committee of the American Mining Congress, of which Henry M. Payne, of the Bertha Coal Co., is chairman, met at a luncheon, Saturday, May 3, held in the rooms of the Machinery Club, 50 Church St., New York, James F. Callbreath, secretary, American Mining Congress, occupying the chair.

It may be said from the outset that the purpose of the American Mining Congress, as expressed by its secretary, is not to add another element of confusion to that already existing in regard to the export problem. The purpose of the Congress is to serve all elements in the industry, and to bring about coöperation between them. The wholesalers have discussed or are discussing the problem; the National Coal Association has attacked it without arriving at definite conclusions, and the United States Bureau of Mines has its own suggestions formulated.

There is a risk of cross purposes, and to avoid any such unfortunate outcome the American Mining Congress, the representative of all interests in the mining industry, is trying to use its coördinating influence. As Mr. Callbreath has well said, the American Mining Congress should serve to allay the present confusion and, should it fail to achieve such a result, it will cease all its attempts to interest itself in the export situation. When it has succeeded in bringing the representatives of the various interests to put their feet under one table its work will end, unless those interests seek its further assistance.

The principal of the informal talks was made by Allen Walker, of the Guaranty Trust Co. Mr. Walker has taken an active part in promoting export associations of many kinds under the Webb-Pomerene act. He stated that the foreign nations all had their export associations. Great Britain, at first, tried to do business without industrial coöperation. The salesmen on their arrival in foreign ports declared that they were not troubled so much by the activity of the German, Japanese or Frenchman as by the competition of their own countrymen. They advised a measure of coördination.

Wedded to their methods and their trade marks, and confident that their past activities had established for them an enviable reputation, the leaders in British trade resented these suggestions and sent other salesmen, men of larger caliber, but from them they rereceived the same reports. Some of the companies even sent their executive heads to find out the true situation. They finally decided that the best way of handling foreign trade was by an association among all those in the industry. Thus transactions became simplified.

Did they want something of the Government, they approached the proper board with an authoritative and certain voice. There were no longer as many voices as there were exporting corporations. The associations were successful because they hunted in packs. They were busy seeking business and not in struggling for their share of it. The aggregate was larger, so there was more for all. The principle, according to Mr. Walker, should be "No national competition in the foreign field."

A large number of export associations have been formed already in all lines of business. The discussions all started with the conviction that nothing could be done, that each producer would "paddle his own canoe." But ultimately the export bodies were formed and those who at first opposed associations most vigorously became the most enthusiastic of supporters.

Charles S. Keith, of the Central Coal and Coke Co., was in the beginning not at all favorable to the lumber export association, though he is a leading producer of lumber. He ultimately changed his point of view entirely, stating that if he did not sell a stick, a plank or a board of lumber abroad he would nevertheless be an enthusiastic member of the association, for he would realize that it helped him by removing the surplus production from the American market.

To continue to give the gist of Mr. Walker's address it may be said that much of the difficulty in the formation of export associations arises from the opposition of those who have expended time and money in establishing a reputation. Perhaps the goodwill thus created is not as important as the established exporter thinks. Still it is doubtless of some value. What there is of it should be saved. It would be suicidal not to sell at least for some time under trade marks well known in foreign trade. However, the association's name should accompany the trade mark of the individual member of the association. The allocation of orders gives no trouble. They may be apportioned according to the volume of previous foreign business, or in some other way.

Walker Would Unify Voice of Exporters

There is an advantage in dealing with the Government as a unit, as the American Federation of Labor has shown. Labor has practically but one voice. Capital has had the voices of 793 associations with conflicting viewpoints. No wonder the American Federation of Labor with its clearly enunciated propositions has been heard, while the multiple voices of capital have been an unconvincing discord.

As an outcome the meeting voted "That the chairman be authorized and requested to appoint a committee, representing the several coal interests involved, such committee to prepare a report and recommendation for coöperative effort to be submitted to a general conference to be called by the chair." The committee appointed consisted of Henry M. Payne, chairman, representing the American Mining Congress; Allen Walker, acting as advisor; G. M. Dexter, representing the National Wholesale Coal Association; Thomas Ferrell, representing the National Coal Association; and Van H. Manning, representing the Bureau of Mines.

The committee on coal export which called the meeting consisted of Dr. Henry M. Payne, of the Bertha Coal Co.; Henry G. Brown, of Philadelphia; George F. Lee, of Wilkes-Barre; F. W. Wilshire, of New York; and J. P. Walsh, of Pittsburgh. Those present at the meeting were James F. Callbreath, Dr. H. M. Payne, W. T. Coe, representing Mr. Wilshire and London representative of the Consolidation Coal Co.; J. M. Lee, of the Lee Coal Co.; H. G. Brown, of the Blair-Parke Coal and Coke Co.; Allen Walker, of the Guaranty Trust Co.; George M. Dexter, of the National Wholesale Coal Association; Charles S. Allen, of the New York Wholesale Coal Association; R. Dawson Hall, of *Coal Age;* W. P. Harriman, of the Irving National Bank; George N. Reed, of the Newark Traffic Club; G. H. Montague, an attorney with a large knowledge of export business; Francis Caughi, of the Guaranty Trust Co.; Dr. H. Foster Bain, of the United States Bureau of Mines.

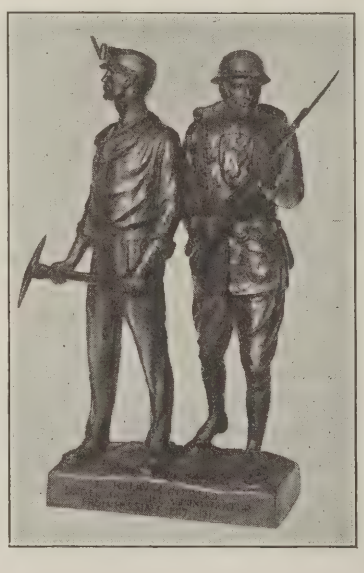
Great Extension of Industrial and Scientific Research Shown in Great Britain

The Mining Association of Great Britain has under consideration the establishment of a single research association for the whole kingdom, to include coal sections or branches dealing with the problems peculiar to particular localities. Valuable work has already been done in this direction at the Doncaster Coal Owners' research laboratory, says the *Colliery Guardian*, and it is clear that there is ample scope for an extension of this work throughout the coal fields of the country.

Encouragement has been afforded for the establishment of research associations by the committee of the Privy Council for Scientific Research, which reports a considerable extension of the work of this new department. Over five million dollars are available to the support of such associations as need governmental financial assistance. But it is open to any industry to establish an approved association without seeking assistance from Parliamentary funds; such associations will be entitled to the same privileges as well as assistance by way of advice and information as those in receipt of a grant. Some hesitation has been shown to establish any relationship with the Government in connection with special researches because of the publicity such a course might entail; furthermore, it is not always desirable that such researches should be fettered by state control.

However, among the numerous schemes initiated by this committee a prominent place is occupied by the work of the Fuel Research Board. Buildings and equipment, estimated to cost over half a million dollars, are now in course of erection for this board; when they are completed a comprehensive chemical investigation of English coal seams is expected. This work, it is stated, should be under Government direction and control. It is not expected that it will clash in any way with the work contemplated by the National Coal Mining Research Association. The latter organization will presumably be mainly concerned with problems connected with the practical work of mining. Already some preliminary work has been undertaken in this direction, and grants have been made by the committee of the Privy Council to the Institution of Mining Engineers for investigations into the atmospheric conditions in deep and hot mines.

Mining Men Will Meet in Chicago



The American Institute of Mining and Metallurgical Engineers will hold its convention in Chicago, Sept. 22 to 26. This meeting promises to be one of decided importance to coal men, for subjects of vital concern to the coal industry will be under discussion.

In addition to the technical talks, an elaborate social program is being arranged, and excursions by the institute as a body are planned to many points of interest in the vicinity, including the steel mills at Gary, the oil refineries at Whiting, metallurgical plants at East Chicago and North Chicago, and operations in the LaSalle district, where are many cement, coal and zinc industrial establishments. The producers of coal should get a glimpse of the manner in which other producers of raw materials solve problems similar to those which perplex the coal industry.

Reception to Dr. Garfield

Of all staffs, few indeed are more enthusiastic than the staff that supported Dr. H. A. Garfield in the work of the Fuel Administration. The members of that organization feel that the operations of their establishment were always conducted for the sole good of the public, that no ulterior motives entered into the actions of their chief. "Without political ambition, without regard to the swarm of Senators and Representatives who sought places for friends, Dr. Garfield pursued the even tenor of his way," is the testimony of one of his associates, who spoke with the memory of a long term of service in the Fuel Administration lingering happily in his mind.

On Apr. 24 the members of the staff held a dinner in Dr. Garfield's honor at the Waldorf-Astoria, New York City. Thirty-eight of the staff, including the one they assembled to honor, were present. The invited guests were few: J. H. Wheelwright, president of the National Coal Association, W. K. Field, ex-president of that association, and T. L. Lewis, acting president of

BRONZE STATUETTE PRESENTED TO DR. GARFIELD BY HIS STAFF

the United Mine Workers of America. Unfortunately, Mr. Field and Mr. Lewis could not be present.

An an evidence of their affection and esteem, the staff presented Dr. Garfield with a bronze statuette of a miner backing up a soldier in the labors of the World War. It is a representation in bronze of the poster which obtained such a large circulation when production of coal was so much desired. It well serves to typify Dr. Garfield's connection with the winning of the great conflict.

No attempt was made to secure attendance of the large number of Dr. Garfield's admirers outside the Fuel Administration, or a larger banquet hall would have been filled to overflowing. It was a "homey" affair where the members of the staff who had worked together could meet in private converse. None of the speeches was given to the public. The souvenirs contained an admirable photo-engraving of the chief and of the bronze statuette illustrated in this article. On the facing page will be found an illustration showing the guests assembled to do Dr. Garfield honor.

Dinner Given to Dr. H. A. Garfield by His Washington Staff, New York City, April 24, 1919

Commencing on the right and passing to the left: W. A. Williams, H. A. Cochran, A. C. Dodson, S. B. Thorne, C. H. Means, G. E. Howes, L. Mitchell, J. F. Mulqueen, Rembrandt Peale, A. W. Calloway, H. Nusbaum, T. B. Gregory, M. L. Requa, J. H. Wheelwright, W. B. Symmes, Dr. H. A. Garfield; W. E. Hope, J. D. A. Morrow, A. M. Ogle, N. S. Schroeder, G. N. Snider, A. M. Macleod, C. C. Marvel, J. T. Lynn, C. B. Nichols, W. A. Marsh, S. B. Crowell, F. E. Harkness, F. M. Whitaker. Up the center between the tables starting from the foot of the table, E. M. Snyder, W. C. Hull, G. N. Allen, H. D. Nims, G. F. Macgregor, J. H. Allport and E. Q. Trowbridge. R. V. Norris and A. F. Hebard came in later, the former having to preside at a dinner at Columbia University.

Investigating Site of North Dakota Experiment Station

The North Dakota lignite field now is being studied by O. P. Hood, so as to determine the advantages of various prospective sites for the lignite experiment station. Mr. Hood is the Bureau of Mines engineer who is in charge of lignite investigations which will be made under the Special Act of Congress passed at the recent session.

The Texas field already has been visited and hearings conducted at Houston, San Antonio, Austin, Waco, Dallas, Ft. Worth and Hoyte. The last named place is the location of a lignite mine. The hearings in Texas developed the fact that an experiment station located there would have large financial assistance from local interests.

The interest shown by Texans in the lignite experiment station was much greater than was known to Federal officials prior to the hearings. It is due largely to the fact that Texas has a very serious fuel problem. Sources of coal are distant. The heavy increases in the price of fuel oil during the war has caused widespread concern. As a result the state is very anxious to make use of its extensive deposits of lignite.

The lignite experiment station is not on the auction block and it will be located at the point where the chances of success seem greatest. The appropriation of $100,000 is regarded as too small for the work in hand, but Mr. Hood is determined that with it, and with such aid as may be forthcoming from the lignite industry, he will prove that lignite can be beneficiated so as to produce a commercial fuel.

Would Combine America's Water Power and Coal Resources

The great war has unrolled the map of the world and hung it above the desk of every engineer and businessman. As a consequence American efficiency must be brought to higher standards. One of the best ways that this can be done is to hitch up America's coal and America's water power. To this effect spoke George Otis Smith on Apr. 16 in the course of his address at the meeting of the Engineering Society of Western Massachusetts, meeting at Springfield. An extract from his remarks on that occasion is as follows:

The phase of conservation that best meets the present day need is conservation of energy; and engineering efficiency has been defined as conservation of labor. Indeed, when the advocate of the supertransmission project proposes power economy for the industrial region extending from New England southward, what he really has in mind is economy of human energy. Displacing steam-generated power with water power or saving coal in the central station instead of wasting it in the small out-of-date local plant are not to be thought of simply in terms of economy in coal. We look back of the coal and see the miner and the fireman. Every ton of coal saved is the 1/900th of the miner's year's toil saved; thrift that is well worth while, if that amount of human energy thus saved is put to a better use. Labor-saving in general means a surplus of man-power available where it is more productive and hence more valuable and therefore worth the higher wage.

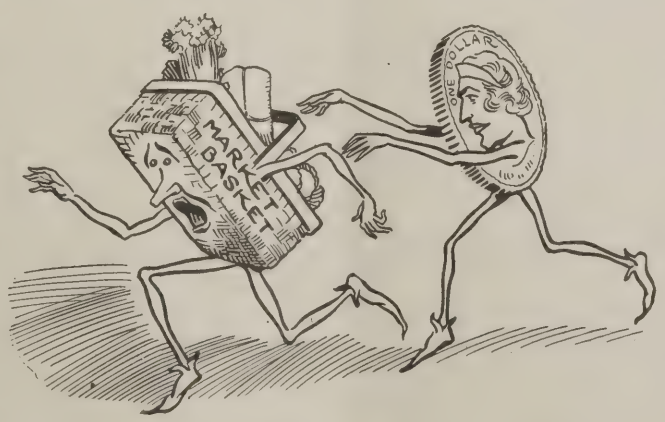
In the second place, industrial New England must plan to safeguard in every way its chief asset—skilled labor. Just as Emerson said that the Civil War had unrolled the map of the world and hung it above the desk of every engineer and businessman, we must now think in terms not of Massachusetts or of New England or even of North America, but of the whole world. Old England has for two years been working on this same plan of consolidation of power systems and centralization of power supply. And the reason for economy is outspoken: to meet American competition in the world markets. With more expensive fuel and practically no water power, England must get more kilowatts from the ton of coal and so reduce the power item in manufacturing costs. On the other hand, it is New England's clue to keep in the lead by making the power supply free from any danger of shortage, such as threatened us in the winter of 1917-1918 and by securing cheaper power and thus increasing its use by every industry. If the British engineers are planning an annual saving of 50 million tons in the fuel account of England, a tonnage twice New England's consumption of soft coal, our own engineers must meet this competition in industrial efficiency. Since modern machinery multiplies man-power, cheap electricity is the only method of harmonizing high wages and low costs. Hitching up America's coal and America's water power most efficiently is absolutely essential if America's standards of living are to be maintained. The super-power plan thus becomes a large item in the human-welfare program.

George S. Pope, who has been in charge of the fuel division of the Bureau of Mines for the past several years, has been appointed chief engineer of the new government fuel yard located in Washington. Coal for the use of government departments in the capital will be stored and handled in this yard.

Coal dumped at tidewater in the Pocahontas region of the Railroad Administration is only slightly less at this time than it was a year ago, according to a report to the Director General of Railroads from the regional director. Coal and coke loadings for other than tidewater destinations, however, have shown a decrease averaging 5000 cars weekly. The regional director in the southern district reports an increased movement of coal from the Alabama district which has been made possible by an improvement in the labor situation.

EDITORIALS

Inflation of Currency and Prices



WHENEVER buyers have much money they can buy much goods, provided prices have not changed. But buyers compete with each other and, given a fixed productivity, prices will rise till the ability to buy reaches a normal level. With prices, wages also rise. This is one theory of price inflation, and quite a reasonable one.

The difficulty is to tell what is money. Certainly gold, silver, nickel and copper currency may be so classified, and so also may paper money. There is, moreover, an equivalent to money in bank deposits, which form the basis of an exchange of credits, making the use of real money unnecessary. Bonds which are readily negotiable, especially Government bonds, are also instruments for credit. A degree of credit, furthermore, adheres in all securities entitled in any way to that name. As a result of the number of media for exchange it is hard to tell just how much money-equivalent may at this or any other time be available. There are degrees in exchange ability, the quality being dependent on the security and on its varied conditions during its life. The use of a security for a medium of exchange rests also upon the readiness with which the public can and will use that security as a basis for credit.

For these reasons, it is hard to evaluate the amount of money and money substitute now and before the war. But Mr. Austin, in an article read before the Editorial Conference of the New York Business Publishers' Association, and appearing on another page of this issue of *Coal Age*, certainly showed that the medium of exchange had far more than doubled. It would seem that it should have become cheapened, therefore, far more than one-half. But money has not been so greatly cheapened, as everyone knows. The price of things in general has been increased about 55 per cent. The medium of exchange is therefore depreciated to about 64 per cent. of its old value. It would seem, then, that a still further adjustment with higher prices is likely. The reduction in values so long expected by some people cannot come till currency is deflated, and that time is extremely remote. Meantime prices must rise.

This is an uncomfortable fact to all of us, especially to those who have saved money and have not purchased real property; and also to those who have to face increased prices without increased income. But it will certainly make for business progress, as the worst thing a man can do under such circumstances is to forbear to buy. The more real property the individual purchases, the more his wealth will acrue; the more money and evidences of indebtednes such as mortgages he retains, the poorer he will become.

To recite the change in conditions: The quantity of currency with which the world's business is transacted has trebled in volume since the world war first began. Where before the war there were 40 billions of dollars of Government securities, now there are 220 billions, or 5½ times as much. Where in 1913 bank deposits were 27 billions of dollars, now they are 75 billions, or nearly three times as much. All these facts suggest that the trail of high prices does not just at this moment have a horseshoe bend. It is, at least for the nonce, a straightaway and not a kite-shaped track.

DOLLAR WILL NEVER CATCH UP
Since the market basket got war training the dollar has never been able to overtake it.

You can't cut prices. Why then assume the other fellow can? He, like yourself, has cut prices already to the quick.

We Never Were a Nation of Quitters

A NATION, like an individual, is successful if it has the courage and devotion to carry entirely through those emprises in which it engages. The higher the emprise, the greater should be the determination that, once commenced, it shall not be spoiled by a too feeble will. We must carry on, as a distinguished French statesman declared, "till the last quarter of an hour."

It is said that our Allies are a little wearied and disposed to give way to reaction. A little letting up, a little mental and moral sagging has been detected in ourselves. The soldiers want to come back home, and their parents are eager for a chance to welcome them. We want to spend as we spent in earlier days. We do not want to skimp, but to live our lives as in less frugal times.

But we must finish up the mess which the war has left. We must meet the bills for material on which labor has been expended. We must pay those who have fought for us, provide for the insurance of the dead and wounded, take care of the sick and restore to industry those who are blinded or lamed by battle.

Those who have been crying "Stand by the President" have still a chance left to do so. We do not need to follow him in all his policies. Some of them may seem somewhat at variance with those he has formerly advocated, some may seem hardly the best under the circumstances. But what of it? We agree with him at least in the age-long practice of paying our debts and in the unquestionable duty of taking care of our boys.

Honesty is the best policy

always. It is needless, however, to recite this fact as a reason for providing for the payment of our debts. Still it is true, and worthy to be recorded as an interesting, though hardly relevant fact, that a successful floating of the Victory Liberty Loan and a consequent prompt payment of our debts will ease the industrial situation and replace much dangerous idleness by healthy activity.

The staff of every coal company should take peculiarly to heart the appeal now being made for the purchase of Victory bonds; for operating staffs have received for the most part large increase in wage during the war and, earning steadily, have every opportunity to save money. With the mine workers the problem is more difficult. The brain workers, therefore, must be asked to do everything in their power to make up for any deficiency in the subscriptions of the manual laborers, whose time is now broken. It is certain that larger purchases could have been made by industrial workers had they been disposed to greater frugality. At most mines the subscription to the previous loans barely reached $10 per month per man. Such a purchase would today, with slow time, more nearly represent the greatest sacrifice possible; but it can in most cases be made, and it will be borne with comparative ease when the coal market again becomes busy.

If we depress the prices of others we shall depress our own prices. As the Italians say "One hand washes the other." The close-fisted purchasing agent, at this present time, is wrecking other people's business as well as his own, and he doesn't get his lower prices after all.

Use Judgment in Floating Liberty Bonds

OUR NATIONAL honor is engaged to the buying of the present loan. We owe it to the returning soldiers—and yet more to those who will never return—that every bond be subscribed. We also owe to the returning soldiers employment and, as far as may be, steady employment. The slogan of the Department of Labor is "For every star, a job." It is a splendid sentiment; every employer, every buyer will do well to heed it. A printed copy of it might even be put on the desk of the chief of the Railroad Administration for his admonishment. But that is neither here nor there.

The bond issue must be bought and to this end all our spare funds should be dedicated. Those who are in receipt of salaries and wages should buy in installments as largely as they possibly can and pay for the bonds as fast as they are able, by a large measure of self-negation. Do not fear that by such self-denial the retail traders and those trades which feed them will suffer and men be laid idle. Those industries are even now doing well. All the luxury trades are booming. They have no reconstruction woes. Theirs are rather reconstruction joys and triumphs. The only troubles they have are growing pains. Their wings can be clipped, not a little but much, and no harm will be done anyone.

But the call to drastic economy in buying does not apply to all industries. We need to keep business going for the returning soldier. Thus it is not advisable to avoid expenditures for building, because the building trades and the basic industries dependent on building need stimulation. To erect a house or factory is a patriotic—and profitable—act, especially if the payment is spread over a period of some months or years.

A man questions in his mind whether he will buy Liberty Bonds or build a house for rent. He has no available savings, but he is in a business which brings him in $1000 a month in excess of frugal living costs. The house could be built for $2000. If he could spread the $2000 over 10 months, the house would cost only $200 a month, he could then pay $800 a month for Liberty Bonds and so buy $8000 worth. If, however, he decided to pay for his house with the first two months of saving, the building would interfere with the purchase of four times its value in Liberty Bonds. Rather than do that he should forego his building and buy $10,000 worth of Liberty Bonds and thus put his whole ten months' income at the disposal of industry. It would be still better for him to put the whole $10,000 in the building of five houses and thus afford shelter to those who find such accommodation increasingly hard to secure.

The same rule applies to larger and smaller investments. We should aid languishing industries by purchases, for that will be as great a national help as buying Liberty Bonds, provided the payments for the work effected will be spread over as long a time as would be the payments for the Victory Bond.

It is to be regretted that the new Liberty Bond issue did not provide for some expenditure on behalf of the reëstablishment of business. It is a pity that when the soldier returns he should find the National Government ceasing to make all kinds of perfectly normal purchases.

Something has been said about the danger of compelling the banks to carry the national indebtedness. It is said that for the good of business they should not buy too large a proportion of this Victory issue. There is certainly a danger to industry should they purchase too many bonds, but it is true also that the needs of industry will be small if no construction is attempted.

We were almost betrayed into writing "America first" as our rule. Perhaps a better maxim would be "Our valiant American defenders first." We owe them a job therefore let us do our utmost to provide them with it. If we don't want to build a house or a workshop or buy machinery or coal on time payments, then let us buy Liberty Bonds to the limit. But if we can arrange to give work directly to the boys who jeopardized their lives in our service or if we can do it indirectly by stimulating the industry in which they work let us do it. They saved us. Let us now take off our coats and fare forth to serve them.

If the salaries of purchasing agents were raised we would have prosperity in a hurry. They just simply "can't see" high prices, because they are not getting the high wages to meet them. This fact is the reason for their soreheaded pessimism.

We hear it questioned whether there are compensations for the grim cruelties of war. Certain it is that there are compensatory pleasures in surrendering our own wills for the nation's benefit. The Liberty Loan still has a few days to run. Still there are a few hours during which we can put our patriotism to the acid-test. Not what we want to do with our money is the question, but what the nation needs. One more triumphant effort, one more surrender to the public welfare before peace is signed! Let us say we kept the faith to the very end.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Slackness of work in the bituminous region has made strikes less frequent than they would otherwise be in that portion of the field. Men are always keener for work when there is not a great amount of work for them to do. In the anthracite region with the prospect of steady work comes the prospect of strikes about every little matter.

Thus at the Bellevue mine of the Lackawanna Coal Co. the men struck Apr. 28 owing to the discharge of two men who are said to have been dropped without cause. As a result 1500 men were laid idle. In Apr. 29 a strike rendering about 500 men idle occurred at the Drifton mines of the Lehigh Valley Coal Co. Apparently the company had loaded an excessive amount of coal produced by company or day hands, which is known as "company coal." The miners felt that this company coal reduced their own possibilities of earnings. There was also a dispute as to sheet-iron and dead-work charges. However, the Buck Mountain and Eckley "feeders" of the Drifton colliery continued at work.

It is surprising that Chris. J. Golden, the union president of District No. 6, has declared for Government ownership of mines. With the steady work in the anthracite region and the prospect of a continued shortage of coal it is also strange that he is advocating the six-hour day with five days a week. He is looking to establish the closed shop. He wants a 100 per cent. organization, no man to be employed who will not pay dues to the union. He hopes that all this will come about in 1920. The contract cannot be made till April of that year, but when the time comes to contract for the labor of the anthracite mines he would have these terms inserted. He says he will sign no agreement that does not concede them all.

Representatives of the employers of the State of Pennsylvania and representatives of the labor employed in that state were unable to reach any agreement at a conference on Apr. 28 regarding proposed increases in the schedules of compensation benefits. The employers took the position that they were willing to support the proposed changes in the administrative features of the compensation law, but declined to discuss amendments increasing benefits.

A conference with the Governor when representatives of the employers and labor will lay their case before him will be held next week, and whatever the outcome of the scheduled conference may be the labor people are determined to make a fight for an increase in benefits.

On Apr. 28 the big strike of the Southwest mine workers came to an end, the miners securing all their demands.

Labor Opposes Undue Price Reduction

While, during recent weeks, there has been a lurking suspicion in some parts of West Virginia that certain operators were cutting prices to a point below the cost of production, it was not until the publication about Apr. 25 of the prices at which a few operators in the Fairmont and northern West Virginia fields had sold coal during April to certain railroads that such suspicions were verified.

When the prices were published not only was there a vigorous protest from other producers but the representatives of the United Mine Workers accused the Director General of Railroads of bad faith, directing specific attention to his promises that no reduction in the selling price of coal which would affect the wages of labor would be encouraged.

When it became known that certain operators were selling coal at $1.60 a ton, H. E. Peters, district organizer, District 17, in charge of the Fairmont office of the district, gave out the following statement: "One of the most interesting reports current today is to the effect that operators in the Fairmont field have been selling, and contracting for the sale of, coal at less than $1.75 per ton, which is ridiculously below the price of coal in the Fairmont field, as fixed by the Government, which price was $2.50 per ton.

"Past and present experiences demonstrate conclusively that Fairmont coal cannot be mined and sold and present wages maintained at these prices. There must be some sinister motive back of this movement that seeks to reduce the selling price of coal in the Fairmont field. If the motive is to reduce the cost of production by reducing wages, then the officials of the United Mine Workers of America wish to serve notice on operators of the Fairmont field, here and now, that we will not stand for any such reduction. There is a temporary depression in the coal trade but that fact should not be taken advantage of or used as an excuse to cut prices. The operators who do so will bring a curse upon their own heads.

"Walker D. Hines, General Director of Railroads, has advised the international officials of the United Mine Workers of America that there would be no reduction in selling price, which would affect the wages of the miner and he also promised that there would be no unfair advantages given to one group of operators over another. Railroad coal would be purchased in general markets at general market prices.

"We are suspicious that there are some sharp practices between Mr. Hines and individual operators in the Fairmont field and we wish to advise them again that this is no time to even attempt to revive these old and unfair competitive conditions."

Arkansas Labor Union Loses Bache Case

It will be remembered that the Coronado County Mining Co., Franklin S. Bache, president, a company operating in Sebastian County, Arkansas, sued the United Mine Workers of America for damages incurred when members of a local union made a raid on the property of the company located at Jamestown, Ark. A judgment was given for $600,000, three times the damages substained, that being the proportion required by the Sherman Anti-Trust Law when by a conspiracy damages are inflicted on one who appears later in court as a plaintiff.

To the $600,000 was added $120,000 for interest so that the total was $720,000. The decision was rendered by a jury in the United States District Court, sitting at Fort Smith, Ark., November, 1917. The mine workers appealed, and arguments on the appeal were heard in St. Louis last December. The United States Circuit Court of Appeals handed down on May 2 a conditional affirmation of the judgment rendered by the District Court.

Judge Trieber, with the concurrence of Judge Sanborn, in his opinion dismissed all the assignments of error made by the miners' counsel with, however, one exception. Judge James D. Elliott, who tried the case in the District Court four days before the case went to the jury and four days after the case came up for trial, granted the coal company the right to ask that interest be added to the judgment.

Judge Trieber ruled that this fixing of the interest to be added, while the trial was in progress, was an error. He ordered that the coal company, within 40 days, file a remittitur of this interest. Unless this is done, the decision says, the case will be remanded to the District Judge for retrial. Judge Hook handed down a dissenting opinion in which he said the case should be remanded because of instructions given by Judge Elliott, which had the effect of coercing the jury into returning a verdict in favor of the coal company.

Leave Your Explosives Outside

Safety Letter of
Consolidation Coal Co.
To Its Safety Committees.

RECENTLY, at a neighboring mine, a miner set down a keg of powder in the blacksmith shop. As is only too usual, he had punched a small hole in the top with his pick. The blacksmith was making a weld as the man set down his keg. A red hot spark flew in the open pick-hole and set off the powder.

One man was killed instantly and another horribly burned. Just a moment of carelessness, but it cost one man his life and frightfully mutilated another. The hole that was open in the top of the keg was not over a quarter of an inch wide and yet a spark which might have landed anywhere in the shop chose this little quarter of an inch of space for itself and found its way into the powder.

The unexpected, the improbable or the seemingly impossible, not only can happen but does happen frequently. You cannot depend on luck to prevent accidents. You must prevent accidents by not taking chances. Explosives are made to explode, that is their business, and you would be the first to complain if they failed to explode. In the interests of your safety, rules have been made concerning explosives. They must be stored in a safe place. Powder jacks must be airtight and a top must be kept on them. Blasting caps must be kept separate from other explosives. These rules are only the teachings of common sense, and if common sense teaches you that you must not stick a lighted match into a keg of powder, does it not teach you just as plainly that you must use constant care in handling your explosives from the time you receive them at the magazine, until you explode them in the blasting of your coal?

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Perils in Reconstruction

Letter No. 6—In reading the several letters that have appeared in *Coal Age*, regarding the work of reconstruction following the great war, I have tried to view the question from the angle of each writer and beg to offer a few thoughts of my own.

All will agree that we have entered a new world in which changes follow each other so rapidly that, before we can adapt ourselves to one set of conditions new ones arise. The period of reconstruction following the great war is already here and has brought with it difficult problems that are proving troublesome to adjust satisfactorily. Many of these problems are without precedence to guide us in dealing with them. Their solution will call for the exercise of the best qualities of patriotic and thinking men. The business opportunities in the industrial world are such as have never before been witnessed.

The remark of Thomas Hogarth, *Coal Age*, Feb. 13, p. 333, appeals to me as practically correct. He says, "Before there will be any great change for the better, we shall experience a change for the worse," and we are now expriencing that prediction. The industrial world, today, is almost paralyzed, the condition being one of expectant waiting. Thousands of working men are idle. Our own mine, employing 100 men, shut down recently; and the mines in many other places are working but half-time, a number being closed for lack of orders.

Facing this industrial paralysis, which it is hoped is only temporary, are the high prices of provisions, clothing and other necessities of life. The high cost of building materials of every kind has caused the cessation of all work of construction, except what is absolutely necessary. Merchants decline to purchase more than what will satisfy their present needs, fearing a general drop in prices. Even iron furnaces are run only to fill urgent orders. How long this state of affairs will continue can only be suggested.

PATRIOTISM AND THE LABOR QUESTION

My thought is similar to that expressed by Joseph R. Thomas, on page 332, of the same issue to which I have just referred, where he says, "We are now facing a crisis that will demand the best judgment of miners and operators alike. The most difficult of the problems liable to arise is the adjustment of labor questions." It is my belief that the present labor problem is a serious one and its adjustment must, to a large extent, depend on the patriotism of both capital and labor.

Never has there been a time, in the history of our country, when a mutual spirit of coöperation was more needful than now. Labor must bear in mind that it cannot destroy capital and live, and capital must remember that to crush labor is to despoil its own usefulness. Both are vital forces in the industrial world and must work in harmony, displaying a spirit of patriotism and common sense, in order that each may live and prosper.

War conditions have spoiled manufacturers and producers, as well as wage earners. Such was the demand for labor that men without skill received from $6 to $8 a day for attending a machine that almost any boy could operate. The common hatchet-and-saw carpenter was paid from $5 to $7 a day for his labor. Producers of all classes of materials and supplies made enormous profits, amounting to 200 and 300 per cent. on the cost of production.

These conditions now no longer prevail, and it is difficult for men to get down to the old pre-war prices. Labor is restless, and a new basis of values will have to be established, before any adjustment of industrial problems can be reached. To avoid serious consequences, however, there should be no reduction of wages, until the cost of living has ben reduced. Then, as Thomas Hogarth has remarked, "let us look boldly at these perils and do what we can to overcome them before they are upon us."

In closing, allow me to say that we shall come nearer to the true solution of our problems through the exercise of good business sense and patriotism, rather than by attempting legislation and adopting extreme views and methods. It is well to be optimistic, but there is danger in an optimism that is not warranted in the world of facts. It is not possible to operate a coal mine long on optimism alone. Let us start right and allow our business sense to prevail, making it possible for all classes to live and prosper.

JOHN ROSE,
Dayton, Tenn. Former District Mine Inspector.

Correct Accounting

Letter No. 3—A recent writer in *Coal Age*, speaking of mining costs, reveals the prevailing disgust or dislike that many mining men manifest when discussing costs of operation. I refer now to the letter of Thomas T. Brewster, which appeared in the issue, Mar. 13, p. 501.

While it is readily admitted that no amount of pen-and-ink work will render a physically unfit or poorly managed mine profitable, it is yet possible to humanize and make clear the cost of operating even the smallest mine, by adopting an accurate method of accounting for all equipment and material purchased and in use. Even allowing that what supplies and equipment are purchased during the year will be paid for by the year's business, let me ask if that is any reason why this year should be burdened with the expense due to the purchase of material and equipment that will be used for years to come?

Moreover, as suggested by the editor, who has added a few comments on this letter, how would it be possible to show the present condition of the operation, or arrive at a proper valuation of the property, if the plant were suddenly destroyed by fire and the book accounts were all that remained to tell the story? Suppose, for a moment, a haulage motor is purchased at a cost of $9000, and let it be assumed that the machine

has a probable life of five years; it would certainly be unfair to have the tonnage for the purchase year pay the capital sum of the cost of the motor, while the remaining four years are charged only with its cost of maintenance and repairs. Can anyone deny that it would be more fair to distribute the first cost of the motor so that each year of its life would bear the due proportion of that cost?

My opinion is that buildings and other equipment that become a permanent and improved part of the plant should be charged as capital invested, since they are an asset that must be reckoned in any future valuation of the property for the purposes of sale or insurance. All rails, timber and other supplies needed for daily use should be charged as supplies to the stock or supply account and only carried to the expense account when taken out and used.

However, it is important to remember that a system may be as complex as you choose to make it and yet fail of the desired effect if the actual operating heads of the different departments are indifferent or incompetent. The question of how large a stock of castings or supplies must be carried is one to be decided by each manager. But, ample supplies are insurance against idleness and often prevent very costly delays.

———, Penn. SUPERINTENDENT.

Firebosses as State Officials

Letter No. 3—In the issue of *Coal Age*, Mar. 20, p. 544, Robert A. Marshall asked to hear what arguments can be advanced for and against the employment of mine firebosses by the state. While I can think of no good reason why firebosses should be thus employed, a number of reasons suggest themselves in opposition to such a plan.

In the first two paragraphs of his letter, Mr. Marshall sets forth clearly the necessity of the employment of firebosses, who he claims should be considered as acting in the capacity of "mine examiners." He states that he is not in favor of their employment by the state. In his third paragraph Mr. Marshall argues that "these men should be in the mine during the entire day."

Analyzing the Situation Carefully

Now, it is well known that most state laws require that the firebosses shall examine the mine before the men enter the mine for work in the morning, and a few state laws require, besides, a second examination to be made by the same or other firebosses during working hours, while the men are in their places. In my opinion, it is obviously out of the question to expect that the firebosses making the first examination, in the early morning, shall remain in the mine throughout the day. Furthermore, that is not necessary, inasmuch as most if not all state laws require the mine foreman and his assistants to look after the safety of all men employed underground.

In addition to the arguments already set forth against the employment of firebosses by the state, I want to ask why it is not just as important that mine foremen and assistant foreman should be likewise employed by and under the authority of the state. All of these officials are charged with the same duty of caring for the safety of the men who work in the mine. For a failure to discharge those duties, any of these officials can and should be prosecuted. It is my belief, however, that their employment by the state would neither emphasize these duties nor insure their faithful performance.

On the other hand, assuming that the fireboss is a state official, would it not be true that it would remove him from the jurisdiction of the foreman and prevent the latter being held responsible for the conduct of the mine, in respect to its safe operation? Would not such a condition of divided authority result in a lack of mine discipline?

Under the present system, state authority in mines is represented by the state mine inspectors, who are charged with the duty of seeing that all mining operations, in their respective districts, are prosecuted safely and in compliance with the requirements of the law. It is up to the state inspectors to see that any violators of the laws are punished.

Practical Effect of State Employment

Let me say, here, that a state-employed fireboss, having an exaggerated idea of his own importance and clothed with state authority, could cause a mine foreman all kinds of worry and trouble and seriously hamper operations in the mine. There is hardly a question but that some firebosses, if clothed with such authority, would not be slow to make their presence felt, in which case relief would be hard and slow to obtain.

To my mind, there is no more reason for state-employed firebosses in mines than for our state-employed factory and mill inspectors being used as operatives and made a part of the organization of the factory or mill. State mine inspection is a very proper and necessary precaution and safeguard, and is welcomed by every well-meaning mine operator. But, there would be strong objections to the presence of state-employed operating officials in the mines. Let me say emphatically that the mine foreman is and, properly should be, responsible for the safe operation of the mine; but he cannot be charged with this responsibility without he has full authority over everyone employed underground.

EDWARD H. COXE, Gen. Mgr.,
Braznell, Penn. Snowdon Coke Co.

Exhaust from Steam Pump

Letter No. 3—Referring to the question of disposing of the exhaust steam from a pump located in a mine, allow me to cite an instance of this kind that occurred in a mine where I was employed some years ago. The pump was located in the bottom vein and handled all the water coming from the four veins above. The heat from the steam pipe that supplied the steam to the pump, and from the pump itself, together with the annoyance of the steam exhausted into the airways, made it necessary to resort to some means of disposing of the exhaust in some practical way.

The arrangement of the mine was such that it was possible to carry a split of fresh air through the pump-room, after which it was conducted, by means of an air bridge built over the main intake airway, directly into the main return and passed out of the mine. Another split of fresh air was carried directly to the men working east and west of the main slope. Notwithstanding these facts, however, such was the heat caused by the pumping arrangements that the men were forced to strip to the waist while at work.

The plan that was adopted to overcome this difficulty was as follows: A condenser was provided and placed in the main airway, at a point where a 4-ft. dam was

built across the airway. The dam is always full of water, which is permitted to flow over the top of the wall and run a short distance down the airway to the sump. The exhaust steam from the pump, which was located about half-way between the sump and the dam, was conducted to the condenser at the dam where it was condensed and passed off with the water. The cold water continually flowing into the dam kept the condenser cool and enabled it to do its work.

Previous to building the dam and erecting the condenser, the exhaust steam from the pump had been conducted into the sump below. But, by this arrangement, the sump water was kept in a boiling condition, which greatly interfered with the efficiency of the pump. I should also state that another dam was built in the airway at a point below the sump, so as to prevent any water from running further down the slope.

Although it is not stated in the inquiry that started this discussion, where the pump is located, my advice to the assistant superintendent is to try and conduct all the hot air and steam, from the place where the pump is located, directly into the return airway. Steam or hot moist air almost invariably makes a dangerous roof condition in a short time. As a general thing, it acts also on the pillars and entry ribs, causing them to crumble. RICHARD BOWEN.

West Pittston, Penn.

Letter No. 4—Referring to the inquiry regarding the question of whether the exhaust steam of a mine pump should be conducted into the suction or into the column pipe, *Coal Age*, Mar. 20, p. 549, let me say that I agree fully with the editorial reply given on the same page.

As there explained, the exhaust of a mine pump operated by steam is often conducted directly into the tail pipe of the pump, but using the precaution to enter the pipe at a point sufficiently below the pump to insure that the steam will be injected into the water. Then, with a little care in starting the pump, there should be no trouble from back pressure or pounding.

On the other hand, however, should the exhaust connection be made with the discharge pipe, water-hammer would result and water would undoubtedly flow into the pump through such connection.

In addition to the above, let me suggest attaching some form of a condenser to the exhaust pipe, which will not only increase the power of the pump but require less speed to run it and obviate the disadvantage of exhausting into the air or even into the suction pipe.

Of course, the use of a condenser on a small pump that is used for local pumping only, is not economical; but wherever any considerable pumping is to be done in the mine a condenser should be installed.

Sugarloaf, Penn. JOSEPH LAWRENCE.

Cost Reduced in Machine Mining

Letter No. 2—Since reading the letter of John H. Wiley, *Coal Age*, Mar. 13, p. 501, I have been looking for something further on the matter of cutting coal with machines. To my mind, it is certainly a subject that should interest all coal men, and I cannot but feel that others than myself were surprised at Mr. Wiley's statement that his cutters "easily cut from 15 to 20 places in a single night." That is going some and certainly speaks volumes for either the cutters or the machines.

While not familiar with the machine he mentions or the "special bit" used in that machine, I made a little calculation somewhat as follows: Assuming that Mr. Wiley's machines cut an average of 18 places, 20 ft. in width, in 8 or even in 9 hours, this would mean $18 \times 20 = 360$ ft. cut, or an average of 45 ft. an hour ($2\frac{1}{4}$ places), for an 8-hour shift; or 40 ft. an hour (2 places), for a 9-hour shift.

All mine bosses should read Mr. Wiley's letter to their cutters. He states that he has installed two machines, the performance of which has more than exceeded his expectations, no machineboss being required to look after the machines and keep them in good condition, as the machinemen themselves easily repair their own machines.

If these machines are new, they should not need much attention in the way of repairs. But, let him wait until the mine has developed sufficiently to require 10 or 12 times that number of machines. Most of them will then be old and need frequent repairs, and things will not be apt to run along so smoothly. This is not to say, however, but that machinework is far superior to pickwork, both in economy and output.

As an illustration of what some machinemen are doing, let me cite an instance, by way of contrast. Only a few days ago, while waiting for the mine foreman to come out of the mine, I was approached by a big strong-looking fellow who was seeking a job. He claimed to be a coal cutter and stated that he had been working in a mine only a few miles from here.

In response to my inquiry as to the cause of the man's leaving his old place, he said that he had no good boarding place. He added that he had a good job cutting by the shift and admitted that he was paid for a whole shift whether he cut one or five places, the latter being the largest number he had cut in a single shift. At that moment, the foreman came in sight and I was glad to tell the man that he had better stick to his old job and left him with that advice.

TWO POINTS OF INTEREST IN MACHINEWORK

There are two things worthy of note in Mr. Wiley's letter. In the first place, he should have given a full description of the special bit used in the Sullivan machine he mentions. It must be the particular form of the bit that enables those machines to cut from 15 to 20 places in a single shift. A description of the bit would be of interest, and I hope this will be forthcoming in some later discussion.

Another point to which attention should be called is the amount of bottom coal that Mr. Wiley says they are leaving. When using the Sullivan machine, it is possible that it may be necessary to leave "from $4\frac{1}{2}$ to 5 in. of bottom coal"; but this is not required in the use of the old Goodman machines that we have at work in our mines.

With us, the cutters are expected to catch the bottom on the back of the cut, while leaving but 2 in. at the front where the cut is started. I wonder if it has ever occurred to Mr. Wiley that the leaving of 5 in. of bottom coal when making a 6-ft. cut across a place 20 ft. wide means a loss of $\frac{5}{12}(6 \times 20 \times 80) \div 2000 = 2$ tons of coal, which is then left in each place. Or, when cutting an average of 18 places a night it would mean the loss of 36 tons left as bottom coal, each shift.

We are all anxious to know how to reduce costs in getting out coal and will gladly receive any suggestion

having that as its object. There is nothing new in the superiority of machines over pickwork. But the avoiding of delays in the movement of the coal from the face to the tipple is an even greater factor in reducing the cost of operation.

In our mine we are doing everything possible to keep the roads in good condition, so as to prevent wrecks and expedite haulage. Machine bosses look after the machines and make needed repairs; an electrician supervises the power lines, sees that the rails are well bonded, and attends to other electrical matters; the foremen and firebosses look after the ventilation of the mine, which is provided with a good ventilating fan and good air-courses.

Our men are not required to work in bad air or wet places and are promptly supplied with all needed material in their working places. They do not need to hunt in other places for timber or rails, and are not kept waiting two or three days for a switch to be laid before they can get cars up to the face. By attention to these details, we try to increase the daily ouput of coal, which will certainly reduce the cost of operation.

McIntyre, Penn. THOMAS HOGARTH.

Efficiency of Mine Officials

Letter No. 7—For some time past, my duties have been to study the organization of industrial plants both large and small, and it has given me great pleasure to note the drift of the discussion in *Coal Age*, relating to the efficiency of mine officials.

Long and close observation has convinced me that, in nine cases out of ten, when a foreman is upbraided by one of his superiors in office it is not the foreman who is at fault as much as those above him. The real source of the trouble can generally be traced to the fountainhead, which may prove to be the general manager or even the president of the company.

The average coal-mining man will claim that, almost without exception, the mining of coal is fundamentally different from the work in other industries. It will be explained that the complexity of the operations necessary to extract coal from the ground and prepare it for the market makes it difficult to operate a coal mine on an especially efficient basis. That this is a fallacy has been proved by the success of men who have made the greatest advances in coal-mining methods and practices.

Criticizing the Higher Officials

The thought of criticising the president or general manager of a large coal company may cause a feeling of horror. While it is known that these high officials have often been severely arraigned behind their backs, few have attempted to lay the blame for low production, or increased cost of operation, on the shoulders of these higher officials.

Let me say, here, that I am not a disgruntled foreman, a disappointed salesman of mine equipment, an unsuccessful efficiency engineer, or a minority stockholder. I am simply a man who has had the privilege of traveling through many coal fields and interviewing many coal officials, in an unofficial capacity. In other words, I am an "observer," without prejudice or malice. From this viewpoint, allow me, then, to give a few illustrations prompted by my personal observations:

Suppose, for instance, the management of a large bakery hires capable bakers but supplies an inferior flour or yeast and, on receiving complaints from customers regarding the poor quality of the bread, went into the bakeshop and upbraided the bakers, only to be told that it was the flour or the yeast that was to blame, and he replied, "A d——poor excuse for a baker to offer when his bread is poor." But, it is just as foolish to expect that any good foreman or superintendent can produce results in a mine when he is not provided with suitable tools and equipment for the work.

Defective Power Distribution and Poor Equipment Cause Loss in Tonnage

As another illustration, let me cite a large coal company operating two mines, one in Ohio and the other in Alabama. The Alabama mine falls far short of producing the results attained in the Ohio operation. The management calls for an explanation and is promptly informed by the Alabama superintendent that he has not the power required to haul the coal.

An examination of the books, however, shows that the Alabama mine has apparatus that will give twice the electrical energy available at the Ohio plant. The prompt dispatch of an electrician, from the home office to Alabama, results in the discovery that the distribution system at the mine is defective, the installation having been poorly made, which is causing excessive line losses. Here, also, the blame for the poor results obtained in the Alabama mine should rest on the shoulders of the management, who alone were responsible for the equipment of both the mines.

Below the "Mason and Dixon line" there are, to my knowledge, four mine superintendents who, for the past three years, have been wanting certain equipment that would enable them to produce a much larger tonnage for the same cost of operation, besides keeping a more satisfied lot of men. The arguments of these superintendents, however, have fallen on the deaf ear of a general superintendent who is an autocrat. While he tells his men that they can have anything they want, their requisitions sent to the office are regularly changed to conform to his own ideas and inclinations.

This same high official, at the time of a recent election, absented himself an entire week from his office, being more concerned over a $1500 bet he had made on the election than about anything connected with the mines. Notwithstanding these untoward conditions, the aforesaid superintendents are being constantly upbraided for their failure to produce the increased tonnage demanded by the president. Speaking plainly, in this case, the president of the company is responsible for the general superintendent employed by the company, and is the real man who is to blame for the lack of tonnage produced at these mines.

Other instances could be mentioned where the high officials of companies are the ones to blame for the inefficiency of those in charge of operations in their mines. It has been said that "He who scorns with a lordly air the suggestions of his subordinates will, if given enough rope, eventually hang himself." The saying aptly applies to coal mining, and expresses the demotion or ousting of a number of gentry whose names have been adorned with high-sounding titles.

Within the past two weeks I have noted the passing of an assistant manager whose subordinates had all been forced to lead a dog's life. For 14 years this official had occupied, not to say held, a job, being the oldest man in point of service though young in years and without experience. For six of those years, he had acted as assistant manager. Any new idea that chanced to be

brought to his attention by one of the men was sure to be greeted with a sarcastic remark and an aggravating smirk. He had "thought of the same thing for years and turned it down as not being practicable." In fact, he threw cold water on everyone who served under him and was a veritable joykiller.

The change produced by the successor to the man just mentioned was indeed remarkable. The newcomer is a young man also, but possessed of different characteristics. Tactful and bright, he never thinks that he knows *all* about anything, but gives sincere consideration to any suggestions coming from his men. His maxim is "No man can make a success of any job, unless he lets the other fellow help him run it," and he means every word he says.

Effect of Change in Management

Soon after this new assistant manager took charge, another change for the better occurred, and no one felt sorry when, five days later, the superintendent was handed his walking papers. That official had been a particular friend of the "sarcastic dub" previously ousted, and had been getting fat around the waistband. He seemed fairly glued to his comfortable office chair, which he seldom left for a trip into the mine. Sitting in his office, his particular delight was to tell filthy jokes and yarns whenever he could get an audience. The company lost none of their assets when he was shipped.

The new superintendent who succeeded to the office is a fine type of Irishman—the kind of a man that makes everyone want to help him "put the job across." Though he is here, there and everywhere, he never seems to be in a hurry; but you can be sure that he knows what he is after when he starts for the tipple or the mine. There is no worry or fret, and he always has the time and humor to pass a word of greeting with the men. He is not a windjammer, but *he is efficient.*

It is unnecessary to say, in closing, that these changes in the official management of that company wrought a wonderful change in the operations in the mine and that this was quickly apparent on the monthly cost-sheet of the mine. OBSERVER.

Philadelphia, Penn.

Letter No. 8—Speaking of the efficiency of mine superintendents reminds me of an incident that occurred in my own experience, when it was my misfortune to have to serve under a superintendent who was what I would term a "grouch." Almost every time he came into the mine, he wanted to change some plan that I had started.

On one occasion this super visited some pillar workings and stopped the work then in progress on eight pillars, explaining that it would only be temporary as he wanted to work out a plan of his own. I listened to his explanation and then told him that we had tried the same plan some time before he came to the mine and it had failed. This, however, did not satisfy him and, although our present plan was working successfully and we were troubled with very few "bounces," which had been such an annoyance previously, we were compelled to follow his instructions.

The result was just what I had expected. The bounces again occurred more and more frequently; and, I regret to narrate that we had one or more fatal accidents, lost considerable coal and lowered our daily tonnage before he was convinced of his mistake and would permit us to resume the plan he had interrupted.

There is no encouragement in working under such a superintendent. No opportunity is given to a foreman to show his ability, while he is always in a position to bear the blame of others' mistakes. On the other hand, it is a pleasure to work for a superintendent who is anxious to see what ability a foreman possesses and who leaves him to exercise his own judgment until he proves his inefficiency.

On another occasion, I worked under a superintendent who invited all his bosses to attend monthly meetings, for the purpose of discussing problems pertaining to efficiency in mining. He also held first-aid meetings, once a month, when men received training in first-aid work. Those who trained with breathing apparatus were given an allowance of two hours for the work.

There was a safety-suggestion box hung in the mine foreman's shanty, and the men were invited to put their suggestions regarding safety into the box. In this way, many useful ideas were evolved and greater efficiency resulted from the superintendent's efforts to educate and train his men.

Ways of Inefficient Superintendents

Many of the so-called "hundred-per-cent. supers," today, are men who can get out coal, at a smaller cost per ton, without regard to the methods they use or the property they destroy. The cheap coal produced by these men is often the most expensive when a true estimate is made of the losses that follow the adoption of their poor methods of mining. The foreman is not allowed to pay out one cent for cleaning up falls in the air-courses, timbering travelingways and making certain necessary provisions for the safe drawing of pillars.

On the other hand, men are started to skipping entry ribs and room pillars, till these supports become too weak to carry the overburden, and a squeeze cuts off, perhaps, 25 or 50 per cent. of coal that should have been mined later but is now lost beyond recovery. In the working of a high seam, I have observed from 4 to 6 ft. of coal abandoned because the foreman was not permitted to pay two men, each, two days' wages to perform the work necessary to reach the coal.

Too often a superintendent who does not expect to remain long in his place will attempt to make a good showing by building wooden stoppings where rock or cement should be used, and buying second-hand material that will hardly outlast his time, all the while planning to let the other fellow bear the expense when he himself has gone.

My idea of an efficient superintendent is one who is a practical miner, from experience, and has a good technical education that enables him to be familiar with all the uptodate electrical and mechanical appliances used in mining. He should be able to draw plans and superintend all work of installation or construction in and about the mine. He should be a good accountant so as to be able to make correct estimates and reports, both of work and material.

A superintendent should visit the mine regularly and often enough to be fully familiar with its requirements, and be able to discuss the work in hand with the foreman. Should a disaster occur when the foreman and fireboss are both in the mine, the superintendent should be able to lead the rescue work, by his knowledge of the workings and the ventilation of the mine.

———, Utah. CARBON.

[The discussion of "Efficiency of Mine Officials" will close with Letter 11, now on hand.—Editor.]

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

Mixing Acid Solutions

In preparing some electrolyte for lead and acid batteries, it was found that there was on hand two bottles of acid diluted with water to different strengths. The first bottle contained 12 per cent. acid and 88 per cent. water; the second bottle, 72 per cent. acid and 28 per cent. water. We required a solution containing 15 per cent. acid and 85 per cent. water and, there being no hydrometer available, it was necessary to calculate the proportion for mixing the two solutions on hand, so as to obtain one of the required strength.

If pure distilled water had been available, it would, of course, have been possible to dilute the stronger solution with water, until the required strength was obtained; but no suitable water was available. In the emergency, I remember a very simple formula was used to determine the proportions in which two solutions of different strengths should be mixed to produce one of a required strength. Can *Coal Age* give me such a formula and explain how it is obtained. I think this will be of interest to others than myself.

Pittsburgh, Penn. ELECTRICIAN.

It is evident that a larger proportion of the weaker and a lesser proportion of the stronger solution must be taken in order to produce a solution containing a medium percentage of acid, greater than the first and less than the second. Hence, for every part of the stronger solution let n parts of the weaker solution be taken, making $n + 1$ parts in all. The percentage of acid in the new mixture will then be expressed thus:

$$\frac{0.12n + 0.72}{n + 1} \times 100; \quad \text{or} \quad \frac{12n + 72}{n + 1}$$

But, since the required mixture must contain 15 per cent. of the acid, we write

$$\frac{12n + 72}{n + 1} = 15$$

$$12n + 72 = 15(n + 1) = 15n + 15$$

$$15n - 12n = 72 - 15$$

$$3n = 57$$

$$n = 19$$

Therefore, it is necessary to take 19 parts of the weaker solution to one part of the stronger solution.

Available Oxygen

Kindly explain why it is that a safety lamp will burn in the air, but not in carbon dioxide, when the latter actually contains a larger proportion of oxygen than the air itself. I am told that only one-fifth of the volume of air is oxygen, while carbon dioxide is two-thirds oxygen, by volume. And yet oxygen is the supporter of combustion. STUDENT.

Holsopple, Penn.

It is true that carbon dioxide contains a much larger proportion of oxygen than air. The percentage of oxygen, by volume, being: Air, 20.9 per cent. and carbon dioxide, 66⅔ per cent. But, while the oxygen of the air is free or uncombined, that of the carbon dioxide is chemically combined with the carbon. In other words, the oxygen of the air is what is called "available oxygen," while the other is combined.

The combustion of the carbonaceous matter, in the burning of a lamp, depends on the amount of available oxygen present in the atmosphere surrounding the lamp. Where there is no available oxygen the lamp will not burn.

The Halby Shoveler and Loader

I was much interested in reading the description of the Halby shoveling and loading machine, which appeared in *Coal Age*, Jan. 9, p. 67, under the title "Portable Coal Loaders."

Having recently contracted for driving a rock tunnel, 9 x 10 ft. in section, and including 4 miles of gangways, I would like to ask one or two questions relating to this machine. Our gangways must be driven half in coal and half in rock, as the seam of coal has a pitch of 45 deg. It occurred to me that if the Halby machine is applicable to such work, it would be of great assistance to me in the carrying out of my contract.

Kindly advise me which of the two types of the machine described would be best adapted to my work. Also, I want to ask if the front part forming the shovel of the machine is fixed so that it can move vertically. If it moves sideways, does the shovel *only* move or is it necessary to turn the whole body of the machine? Please inform me where I can secure a catalog of the machine. E. N. ALLEN.

Newcastle, Wash.

As was stated in the article to which this correspondent has referred, there are two types of the Halby machine mentioned, the one being 6 in. wider and requiring nearly 18 in. more headroom than the other. The smaller of the two machines, known as the T700, is designed to work in a 5-ft. seam, while the other, the T600 machine, is adapted to higher openings. Both of these types have practically the same length; but in the smaller machine the power and truck sections are separate, while in the larger they are combined.

As stated in the previous article, the discharging conveyor at the rear of the machine is arranged, in the smaller type, to swing, so that it can discharge its material into a car standing on a track at one side of the machine. In the larger machine, the material handled can only be discharged into a car standing behind the machine and on the same track with it, or in direct line with the shovel.

As these machines are well adapted to the class of work mentioned by this correspondent, we do not wonder that his attention was arrested by their description, and we gladly recommend their use for the work in question. For a descriptive catalog, write the Lake Shore Engine Works, Marquette, Mich.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Bituminous (Penn.) Mine Foremen's Examination, Apr. 8-10, 1919

(Selected Questions)

Ques.—(a) For what does the bituminous mining law of Pennsylvania provide? (b) What is meant by the term "bituminous coal mine" and the term "excavation and workings"?

Ans.—(a) The bituminous mining law of Pennsylvania is an act intended to provide for the health and safety of persons employed in and about the bituminous coal mines of the state, and to secure the protection and preservation of mining property.

(b) In the meaning of the bituminous mine law, the the term "mine" includes the shafts, slopes, drifts, or incline planes connected with excavations that penetrate the coal strata. The law continues:

"Which excavations are ventilated by one general air current or divisions thereof and connected by one general system of mine railroads over which coal may be delivered to one or more points outside the mine, when such is operated by one operator."

This addition to the definition of a mine would seem to exclude such excavations in coal strata as are void of ventilation, besides restricting the application of the word "mine" to excavations in coal strata that are operated by one operator, which is obviously not the intent of the law.

The expression "excavations and workings," in the meaning of the bituminous mine law, includes all the excavated portions of a mine, both abandoned and working, together with all shafts, tunnels and other passageways and openings, both in use and in process of making, together with their equipment of material and machinery below the surface of the ground.

Ques.—As mine foreman, what observations would you make in your daily examination of the working places?

Ans.—The mine foreman must closely observe every operation going on in the mine, to see that no unsafe practices are employed and that everything is done in compliance with the requirements of the mining law and the mine regulations. He must examine the condition of each working place to see that the roof is safe and the coal properly mined. He must give particular attention to the ventilation of the working faces and all abandoned areas and other void places in the mine, and see that there is no dangerous accumulation of gas and that all places are healthy and safe for work. He must see that there is a sufficient supply of timber and other material, on hand in the working places and that the same are being properly used.

Ques.—What are the principal requirements on haulage roads to insure the economic haulage of coal?

Ans.—Main haulage roads should be driven as straight as possible and have sufficient headroom and clearance at the side of the track to insure the safe and speedy movement of the cars. The track must be well laid and ballasted and the roadbeds drained. Where electric haulage is employed, careful attention must be given to the bonding of the rails. As far as practicable, steep grades and sharp curves must be avoided on the haulage roads and no doors must be constructed at the foot of a grade where a motorman or driver may be unable to control the movement of the cars.

Ques.—In a certain mine where the heaving of the floor has thrown the track out of alignment and reduced the headroom so much that bottom must be lifted on the haulage roads or the roof shot down to permit the passage of mules and cars, the entries are driven 10 ft. wide on 40-ft. centers and rooms turned off the entries on 30-ft. centers and driven 24 ft. wide. What is the thickness of the room pillars; and, assuming you were taking charge, what suggestions would you make to eliminate these troubles?

Ans.—The chief cause of the trouble, in this case, appears to arise from the small room pillars, which are only 6 ft. in thickness while the rooms are 24 ft. wide. It would be better to drive the rooms on 40-ft. centers and reduce their width to 20 ft., making the thickness of the room pillars also 20 ft. If practicable, the entries should be driven 8 ft. wide, instead of 10 ft., as at present. All rooms should be turned narrow, the roomnecks not exceeding 8 ft. in width and driven a distance of 10 yd. before the room is widened out. Every precaution should be taken to drain the workings and prevent the accumulation of water on the roads or in the rooms, which would soften the bottom and increase the trouble, if permitted.

Ques.—How would you render first aid to a person with a broken forearm?

Ans.—Having sent at once for a doctor, proceed to examine the injury and place the broken limb in as comfortable a position as possible, observing whether the break is a simple or a compound fracture. In the event of the latter, great care must be exercised to prevent the sharp splinters of bone from tearing the muscles and increasing the danger of the wound. If the injury is a simple fracture and the skin is not broken, however, there is little danger of the wound being infected, and the principal object, while awaiting the coming of the doctor, is to prevent any undue movement of the injured limb by binding it carefully to a temporary splint or otherwise securing it in a manner to prevent further injury from the broken bones penetrating the flesh.
